29/11/18

JANUARY to JUNE, 1918

MINING AND
SCIENTIFIC PRESS

420 MARKET STREET

SAN FRANCISCO, CALIFORNIA

INDEX

A	Page		Page
Accidents in Colorado mines.....	454	American Metal Co. and Compania de Minerales y Metales.....	361
Acid chambers, etc., for sulphuric.....	441	New directors.....	Editorial..... 526
Sulphuric, production in 1917.....	265	American Mining Congress, work of.....	Editorial..... 216
Adams, Huntington.....	Nitrate lands in Chile..... 678	American Smelting & Refining Co., company report.....	636
Aerial tram at Midas mine, Alaska.....	275	El Paso plant.....	679, 711
Africa, gold production of, 1912 to 1916.....	645	Fluctuations in lead prices.....	353
Mineral production of South.....	91	Metal business of.....	660
Agitator into continuous thickener, converting.....		v. Bunker Hill & Sullivan Mining & Concentrating Co.....	Editorial..... 109, 503
V. T. Edquist.....	658	American Zinc Institute.....	894
Agricultural land, mineral on.....	44	American Zinc, Lead & Smelting Co., company report.....	842
Air blasts.....	584	Royalties to Minerals Separation.....	574
Compressor, testing.....	W. S. Weeks..... 479	Ammonia, by-product.....	482
Froth flotation, what is.....	505	From by-product coke-ovens.....	446
Ajo, copper-leaching at.....	Courtenay De Kalb..... 187	Haber process for.....	159
Copper mine, I. H. J. Courtenay De Kalb.....	115, 153	Prices fixed.....	653
Alaska, chromite deposits in.....	547	Supply of United States.....	402
Coal Leasing Law.....	405	Amorphous minerals.....	A. F. Rogers..... 266
Copper production in 1917.....	133	Amparo Mining Co., Mexico, operations.....	427
Cosna-Novitna district.....	868	Ore treatment at.....	575
Gold output in 1917.....	91	Anaconda Copper Mining Co., company report.....	875
Hot springs in.....	134	New fume-treatment plant at.....	D. M. Brown..... 895
Mineral output in 1916.....	22	To make ferro-manganese.....	357
Mineral output in 1917.....	92	2000-ton leaching plant at.....	
Mining in lower Copper River basin.....	785	Frederick Laist and H. J. McGuire.....	365
Railroad, progress.....	629	Analysis of Ajo ores.....	190
Alaska Gold Mines Co., affairs of.....	333	Of ore needed in describing plants.....	677
And Alaska Gastineau Mining Co., company report.....	347, 768	Andalusite, where found.....	227
Alaska Juneau Gold Mining Co.....	Editorial..... 183	Andes Copper Mining Co., company report.....	875
Ditto.....	J. H. Mackenzie..... 322	Antimony, bibliography of.....	353
Company report.....	776	In Humboldt county, Nevada.....	127
Monthly statements.....	347	Market, review every week.....	
Situation in April.....	492	Situation of United States discussed.....	899
Alexo nickel mine, Ontario, notes on.....	805	Uses of.....	798
Allen, A. W.....	Source of nitrate and iodine..... 522	Apache trail, Arizona.....	T. A. Rickard..... 257
Alloys, hardness of.....	694	Apex agreement at Goldfield.....	529
Of manganese.....	753	Sail at Pioche, Nevada.....	425
Almaden, California, operations at.....	386	Sail at Tonopah.....	Editorial..... 843
Alum prices.....	894	Suits in Nevada.....	Editorial..... 320
Aluminum alloys in zeppelins.....	784	Argentina and the War.....	Editorial..... 181, 567
And copper alloy.....	120	Credit in United States.....	Editorial..... 741
In bauxite.....	267	Mining.....	Editorial..... 2
Market, review every week.....		Trade with and exchange.....	283
New solder for.....	654	Wolfram in.....	204
Prices fixed.....	391	Argonaut Mining Co.....	383
Ditto.....	Editorial..... 777	Arizona, Apache trail.....	T. A. Rickard..... 257
Primary made in United States in 1917.....	654	Copper districts of.....	836
Production of United States in 1917.....	402	Fish in Roosevelt lake.....	288
Production of the world in 1917.....	304	Mineral output in 1917.....	168
Salts production of United States.....	824	Review of mining in 1917.....	135
Sulphate, notes on.....	658	Arkansas, manganese in.....	52
Aluminum Co. of America.....	267	Zinc discoveries.....	560
Alunite, locating metalliferous lodes containing.....		Armstead Mines Co., Idaho.....	276
J. F. Law.....	881	Arnstad Mines Co., Idaho.....	90
Mining in Utah.....	497	Arroyo gold-mining district.....	E. H. Clausen..... 615
America, North and South, gold production of, 1912 to 1916.....	645	Arsenic prices.....	590
American capital for the Rand.....	Editorial..... 535	Asbestos in Wyoming.....	388
Foreign commerce in 1917.....	Editorial..... 575	Platinized, use of.....	194
Owned vessels.....	719	Asia, gold production of, 1912 to 1916.....	645
Policy regarding silver.....		Assaying at Joplin.....	Editorial..... 842
E. D. Boyle and Whitman Symmes.....	403	Zinc ore at Joplin, Missouri.....	734
American Federation of Labor membership.....	452	Assessment work in Canada.....	835
Americanization.....	Editorial..... 467	Atkinson, E. J.....	Platination of semi-oxidized silver ore..... 575
A. L. P. affairs of.....	3	Atlanta Mines Co., company report.....	734
And iron and steel paper.....	607	Atolia, California, dressing tungsten ore at.....	710
And its name.....	705, 729	Atolia Mining Co. directors.....	386
Butterfield.....	Editorial..... 215	Austin, L. S.....	Operating conditions at Clarkdale smelter..... 487
Combined contract.....	Editorial..... 199	Australia, British Government to buy all zinc.....	634
Engineering, Coal and timber.....	898	Copper production sold to England.....	428
List of members in military service.....	Editorial..... 535	Gold production declines.....	Editorial..... 811
New contract.....	283	Gold production, 1912 to 1916.....	Editorial..... 645
Notes on New York section.....	343	Selective flotation in.....	612
War Minerals Committee.....	363	War expenditure of.....	556
		Zinc and Great Britain.....	Editorial..... 812

	Page		Page
Chemistry, inorganic, new book on.....	394	Colorado, protests against freight rates.....	868
Chetco Mining Co., California, operations.....	457	Report of Smelter Commission.....	276
Chief Consolidated Mining Co., company report.....	393	Smelter charges..... H. F. Lunt.....	470
Chihuahua Mining Co., property of.....	417	Splitting limits in ore-buying.....	620
Chile, copper production in 1917.....	583	Colorado Fuel & Iron Co., company report.....	349
Mining conditions in..... Fritz Mella.....	298	Colorado Mining Co., Philippines.....	615
New taxes.....	564	Colorado Scientific Society.....	395
Nitrate industry in brief.....	522	Colvocoresses, G. M..... Nickel-copper steel.....	152
Nitrate lands in..... Huntington Adams.....	678	Combustion of fuels, efficiency of.....	849
Chile Copper Co..... Editorial.....	877	Commerce Mining & Royalty Co., Oklahoma.....	292
Chilean nitrate, discussion on conditions.....	419	Commercial aspects of shale-oil industry.....	
Nitrate, some history of.....	300	J. H. G. Wolf.....	613
Chimney stack at Anaconda.....	895	Compania del Boleo.....	380
China, currency reform in.....	428	Compania de Minerales y Metales..... Editorial.....	501
Great engineering feats of.....	763	Ditto..... Otto Sussman.....	361
Spelter imported into.....	200	Company reports:	
Chinese antimony and the United States market.....	899	Alaska Gold Mines Co. and Alaska Gastineau Min-	
Mineral production..... Chung Yu Wang.....	288	ing Co.....	809
Chino Copper Co., company report..... 351, 770.....	775	Alaska Juneau Gold Mining Co.....	776
Chino concentrates, analysis of.....	712	American Smelting & Refining Co.....	636
Chloride, Arizona, description of.....	731	American Zinc, Lead & Smelting Co.....	842
Chloride in flotation. J. G. Parmelee, C. A. Wright.....	641	Anaconda Copper Mining Co.....	875
Chrome..... Editorial.....	466	Andes Copper Mining Co.....	875
Brick in reverberatory furnace..... F. R. Pyne.....	60	Atlanta Mines Co.....	734
Domestic production of..... F. A. Rapp.....	113	Barnes-King Development Co.....	356
Industry.....	762	Beaver Consolidated Mines Ltd.....	810
No direct Government assistance.....	872	Belmont Shawmut Mining Co.....	803
Ore imports..... Editorial.....	741	Belmont Surf Inlet Mines.....	876
Ore imports restricted.....	906	Benguet Consolidated Mining Co.....	346
Ores in Pennsylvania.....	488	Bingham Mines Co.....	600
Requirements of America.....	639	Brunswick Consolidated Gold Mining Co.....	393
Situation in California.....	598	Bunker Hill & Sullivan M. & C. Co.....	842
Chromite deposits in Alaska.....	547	Butte & Superior Mining Co.....	842
In Alaska.....	560	Butte Copper & Zinc Co.....	313
In North Carolina..... J. H. Pratt.....	516	Calumet & Hecla Mining Co. and subsidiaries.....	739
Churn-drilling at Sacramento Hill, Bisbee.....	554	Centennial Eureka Mining Co.....	459
Cinco Minas Co., Mexico, operations.....	426	Cerro de Pasco Corporation.....	810
Civilization, mining industry the keystone of modern.....		Cerro Gordo Mines Co.....	636
R. H. Stretch.....	791	Chief Consolidated Mining Co.....	393
Claim location in Portugal.....	863	Chino Copper Co.....	775
Location requirements.....	464	Consolidated Interstate-Callahan Mining Co.....	420
Clar, L. F..... Rifles.....	469	Cordoba Copper Co.....	534
Clark, C. W..... United Verde and labor.....	709	Crown-Reserve Mining Co. Ltd.....	704
Clarkdale smelter, operating conditions at.....		Denn-Arizona Copper Co.....	731
L. S. Autin.....	487	Dome Lake Mining & Milling Co.....	596
Classification of furnace-slugs..... Herbert Lang.....	619	Edna May Gold Mining Co.....	463
Clausen, E. H..... Arroyo gold-mining district.....	615	Electric Point Mining Co.....	563
Clay imports into United States in 1917.....	830	Engels Copper Co.....	348
In Louisiana.....	612	Franklin Mining Co.....	665
Climatic conditions at Ely, Nevada.....	858	Gemini Mining Co.....	274
Climax, Colorado, molybdenite deposits.....	662	Godiva Mining Co.....	274
Climax Molybdenum Co., Leadville.....	276	Goldfield Consolidated Mines Co.....	809
Operations.....	662	Goldfield Great Bend Mining Co.....	869
Cloverdale, California.....	697	Greene Cananea Copper Co.....	871
Coal and the fuel order..... Editorial.....	111	Guanajuato Reduction & Mines Co.....	700
Burned in stoves wasteful.....	584	Hancock Consolidated Mining Co.....	769
Dust firing at McGill, Nevada.....	802	Hecla Mining Co.....	739
Dust firing in British Columbia.....	802	Hedley Gold Mining Co.....	810
Exports of bituminous in 1917.....	152	Hollinger Consolidated Gold Mines, Ltd.....	534
In Alaska.....	405	Homestake Mining Co.....	463
In Canada.....	628	Inspiration Consolidated Copper Co.....	775
In piles, heating of.....	452	International Lead Refining Co.....	875
In Utah.....	583	International Smelting Co.....	875
New Method of burning powdered.....	830	Iron Blossom Con. Mining Co.....	388
Powdered, in blast-furnaces..... Editorial.....	877	Iron Cap Copper Co.....	584
Tar from coke.....	470	Iron Silver Mining Co.....	604
Used in lighting American cities.....	308	Judge Mining & Smelting Co.....	626
Use of powdered..... W. G. Wilcox.....	849	Kennecott Copper Corporation.....	704
Cobalt, Ontario.....	64, 100.....	Kerr Lake Mining Co.....	704
Coeur d'Alene region, Idaho.....	122	La Rose Mines Ltd.....	704
Dividends in first quarter of 1918.....	561	Luning & Idaho Mining Co.....	424
Metal output in 1917.....	494	Mary Murphy Gold Mining Co.....	837
Results of large mines in 1917.....	869	Nass Consolidated Mining Co.....	631
Cochill, Will H..... Flotation of chalcopryite-		McKinley-Darragh-Savage Mines of Cobalt, Ltd.....	704
pyrrhotite ore.....	195	Miami Copper Co.....	775
Ditto..... Molecular forces and flotation.....	747	Michigan-Utah Consolidated Mines Co.....	563
Coke, by-product output.....	832	Mines Co. of America.....	700
Coleman, Texas.....	384	Monarch Pittsburgh Mining Co.....	595
Colins, Edgar A., death of.....	806	Montana-Bingham Con. Mining Co.....	801
Collins, G. E..... Excess profit tax for mines.....	114	Mt. Bischoff Tin Mining Co.....	876
Colloid chemistry.....	266	Mysore Gold Mining Co.....	636
Colloids, tests on.....	238	Natomas Company of California.....	534
Colima, railroads in..... Editorial.....	109	Nevada Consolidated Copper Co.....	775
Commercial metal production in 1917.....	61	New Idria Quicksilver Co.....	768
Crucible..... A. J. Hoskin..... 203, 305.....	625	New Jersey Zinc Co.....	278
Cuba, mining in south-western.....	524	Nipissing Mining Co., Ltd.....	704
Cuba, shale area.....	509	North Butte Mining Co.....	734
Cuba, shale of..... R. L. Chase.....	445	North Star Mines Co.....	600

	Page		Page
Company reports, cont.		New method of determining	James Moir 725
Oseola Consolidated Mining Co.	463	Ore concentrated and smelted in United States.	823
Pittsburg-Idaho Co.	903	Ore imports restricted.	906
Plymouth Consolidated Gold Mines.	732	Prices	Editorial 148, 604
Porcupine-Crown Mines Co.	876	Prices re-fixed	Editorial 777
Portland Gold Mining Co.	356	Producers and price-fixing.	Editorial 357
Powder River Gold Dredging Co.	595	Producers and prices.	Editorial 844
Premier (Transvaal) Diamond Mining Co., Ltd.	609	Producers, small, ask for relief.	Editorial 705
Ray Consolidated Copper Co.	776	Production in 1917, State.	829
Ray Hercules Copper Co.	439	Production of Chile in 1917.	583
Richmond Mining, Milling & Reduction Co.	423	Production of United States in 1917.	119, 808
Reco Wellington Mining Co.	769	Reverberatory furnace, chrome brick in	
St. Joseph Lead Co.	393		F. R. Pyne 60
Santiago Mining Co.	875	Slags at El Paso, analysis of.	711
San Toy Mining Co.	534	Smelting at El Paso.	711
Shannon Copper Co.	842	Sulphide ore, heap-leaching of.	
Shattuck-Arizona Copper Co.	311		G. D. Van Arsdale 149
Silver King Consolidated Mining Co.	496	Copper Basin district, Arizona.	902
Snowstorm Mines Consolidated.	458	Copper Queen Consolidated, Sacramento Hill deposit.	519
South Hecla Mining Co.	666	Copper Queen mine, Arizona, controlling fires in.	
South Lake Mining Co.	424		Gerald Sherman 157
Superior & Boston Copper Co.	629	Smelter, record yield.	275
Temiskaming Mining Co., Ltd.	704	Copper River basin, Alaska, gold in creeks.	446
Tennessee Copper Co.	805	Basin, mining in lower.	F. H. Moffitt 785
Tintic Milling Co.	735	Cordoba Copper Co., company report.	534
Tom Reed Gold Mines Co.	698	Corrosion in float-valves, metal.	P. T. Bruhl 303
Tongkah Harbour Tin Dredging Co.	430	Of condenser-tubes.	364
Trethewey Silver-Cobalt Mines Co.	497	Corrugated iron, substitute for.	27
Tuolumne Copper Mining Co.	495	Cortese, E.	Phosphate in Egypt 374
United Copper Mining Co.	352	Costs at Bunker Hill & Sullivan.	842
United Verde Copper Co.	393	At Homestake mine in 1917.	463
United Verde Extension Mining Co.	393	Factor of labor.	28
Utah Copper Co.	776	Of commodities, rise in.	880
Utah Metal & Tunnel Co.	801	Of copper production by Calumet & Hecla and subsidiaries.	739
Vindicator Consolidated Gold Mining Co.	810	Of dredging tin in Siam.	430
Vulcan Dredging Co.	872	Of drilling in Siberia.	449
Wahi-Paeroa Gold Extraction Co.	739	Of excavation for mill.	340
Wellington Mines Co.	534	Of flotation v. cyanidation.	576
Western Utah Copper Co.	426, 787	Of gold mining.	649
Yellow Pine Mining Co.	371	Of living.	381, 603
Yukon Gold Co.	463	Of oil-shale plants.	613
Compressed air in mining, new book on.	280	Of Oseola company in 1917.	463
Air machinery in Komselter region.	763	Of powder at Homestake mine.	763
Comstock Lode, monthly output in June.	805	Of precipitating gold by charcoal.	763
Operation on.	530	Of producing copper in 1917 by porphyry companies.	764
Progress on.	351	Of producing gold and rising price of commodities.	253
Concentrate, drying flotation.	657	Of producing lead by Bunker Hill & Sullivan.	773
Local treatment of.	576	Of producing oil from shale.	514
Concentrates, analysis of Chile.	712	Of producing tin in Tasmania.	876
Concentrating zinc ores at Butte.	764	Of producing zinc concentrate at Joplin.	813
Concentration by dense solutions.	T. M. Chance 754		Editorial 813
Concrete, density of.	577	Of Yukon Gold Co. in 1917.	463
Fords for crossing streams.	17	Cottrell precipitating plant at Anaconda.	895
Influence of brine on reinforced.	302	Precipitators at Humboldt plant, Arizona.	737
Mixing in cold weather.	418	Crane, W. B.	Drawing pillars in metal mines 407
Rate of application of load.	897	Cresson Consolidated Gold Mining Co.	276
Ships, designing of.	L. R. Ferguson 586	Cripple Creek, Colorado, letters.	
Conic projection, Lambert conformal.	784	211, 208, 344, 382, 420, 489, 520, 571, 731	381
Conserving technical men.	Editorial 814	Crown Reserve Mining Co., Ltd., Canadian.	784
Consolidated Arizona Smelting Co. roasting plant.	335	Silver prices and costs.	98
Consolidated Coppermines Co., Nevada.	274	Crown Mines, review of history.	780
Consolidated Interstate-Callahan Mining Co., company report.	430, 827	Cuba, mining possibilities in copper.	656
Consolidated Kansas City Smelting & Refining Co.	679	Cyanamid plant in Alabama.	46
Construction of slime-dams.		Process for nitric acid.	790
Control of mineral production by Government.	J. E. Thomas and E. A. Osterloh 622	Cyanidation v. flotation, cost of.	576
	Editorial 537	Process for nitric acid.	790
Converters at El Paso.	716	Cyanide of sodium.	W. J. Sharwood 755
Conveyor for slag.	822	Price in June.	898
Copper and aluminum alloy.	120		
At Kolmezi, Belgian Congo.	287		
Blast-furnace at El Paso.	713		
Bliester, notes on.	324		
Deposits on Virginia-North Carolina border.	298		
Determination of non-sulphide.			
C. E. van Barneveld and E. S. Barker.	339		
Electro-deposition of.	197		
Exports.	Editorial 319, 637		
In American ores, average.	718		
In Australia bought by British Government.	428		
In steel, behavior of.	418		
In steel, test for.	127		
Leaching at Ajo.	Courtenay de Kalb 187		
Leaching at Anaconda.	365		
Market, review every week.			
Mines, ore-reserves and result of disseminated in 1917.	764		

D

Dams construction of slime.	622
Devis Daly Copper Co., company report.	801
Deadwood, South Dakota.	273
Debts of countries at war.	650
De Kalb, Courtenay.	Ajo copper mine, I. H. 115, 153
Ditto.	Calumet & Arizona sulphuric-acid plant 437
Ditto.	Copper leaching at Ajo 187
Ditto.	Man-power 815
Ditto.	Sacramento Hill disseminated copper deposit, I. H. 549, 578
Ditto.	Smelting at El Paso, I. H. 679, 711
Ditto.	Texas School of Mines 131
Del Mar, Algernon.	Flotation flow-sheets 221
Denn-Arizona Copper Co., company report.	731
Denver, Colorado, letters.	421, 454, 834, 900

THAT grand old mine, the St. John del Rey, in Brazil, is still vigorous. It is the deepest gold mine in the world, the lowest level being 6066 ft. below the surface. Last year this venerable enterprise yielded a profit of \$335,000, from the treatment of 94,300 tons, averaging \$12.50 per ton.

NERO fiddled while Rome was burning and lives in history as the type of the heedless spectator of a great event. So today, while civilization is sent to the shambles and nations fight for existence, there are people that enjoy dog shows and cat shows, and there are newspapers that think to find interesting copy in such silly performances.

GOLD production in South Africa is suffering from labor shortage. The output of the Rand for 1917 is about \$1,000,000 less than in 1916, Rhodesia and Australia show a decided decrease, while India and West Africa are holding their own fairly well. On the whole, despite the difficulties created by the War, the output of gold in the British dominions is being maintained at a high level, but no new and important discoveries have been made of late.

DIVIDENDS paid by copper companies during 1917 are estimated at \$179,000,000 as against \$157,000,000 in 1916, although the average price of copper was slightly lower. The fixation of the price at 23½ cents caused many reductions in dividends during the last quarter of the year. The Utah Copper heads the list with a disbursement of \$23,555,105 to its shareholders, as against \$19,493,880 in 1916. The Anaconda paid \$19,815,625, and the Kennecott \$15,832,194. Among the young producers the Inspiration paid \$9,751,228, the Miami \$6,537,360, and the United Verde Extension \$2,992,500. The prospect for 1918 is prosperity, but with less lavish distribution of profit.

ANOTHER highly successful amateur golf tournament is reported from Del Monte. Any man that has the spare time and the physical fitness to play championship golf ought to be serving in the Army or Navy. Such public exhibitions of detachment from the War justify the statement, made by the editor of the 'National Service' magazine, that "we are fighting, com-

pared with the other great fighters, approximately a 20% war, in the sense that compared with them we are using but 20% of available resources." By such slackening we face the danger of our failure to end the War, the possibility of such indecisive fighting as will prolong the calamity and increase needlessly our sacrifice of men and material. Let us put aside dog-shows, symphony concerts, and golf tournaments until we have seen this thing through.

ON another page we publish an article concerning industrial conditions by Mr. Charles T. Hutchinson, the manager of the business department of this paper. It is timely and written in a style that will be refreshing to the readers of technical descriptions. Mr. Hutchinson dwells upon the function of advertising and the purpose of such a periodical as ours, which, of course, is to furnish reading matter to those that buy, or direct the buying, of the manufacturers advertised through our medium of publicity. Fortunately those whom we aim to interest are more than commercial agents, they happen to be engineers and captains of industry, constituting a public whom any editor might be glad to address. The realization of that fact harmonizes the commercial and the idealistic elements into a task that lacks neither interest nor usefulness.

BUTTE has had an eventful year, as is shown in the review by Mr. Ben F. Evans appearing in this issue. Besides its copper, with which gold and silver are extracted as by-products, this district is now yielding manganese, so urgently needed in steel-making. We publish a short article on this phase of the local industry. We note with pleasure that the general search for manganese is proving successful, for the U. S. Geological Survey reports that during the first nine months of 1917 the production of first-class ore was 70,225 tons, by 88 operators, as against 26,997 tons, by 55 operators, during the whole of 1916. It is estimated that the total output for 1917 will be 122,275 tons, and that in the current year shipments may increase to 200,000 tons. The States prominent in this good work are Montana, Arizona, California, Utah, and Nevada. In our issue of November 17 we gave details concerning the manganese deposits of Philipsburg, Montana, and in that of November 24 simi-

lar notes concerning the manganese resources of Leadville, Colorado.

THAT the lack of developed mines in the Argentine republic is due to ill-conceived mining laws that fail to stimulate prospecting and exploitation is a statement of great significance coming, as it does, from Mr. Horace V. Winchell, one of the world's foremost economic geologists. In his letter on 'Mining Laws for Russia,' published in this issue, he affirms that the eastern slope of the Andes, lying within Argentine territory, contains mineral resources as great as those in Chile. The liberal policy toward mines on the part of Chile is credited with being the chief cause for the great expansion that has resulted in stimulating her output of mineral products until they now reach a value of \$140,000,000 per year. The contrast between this and the paltry sum of \$300,000, which represents the yearly total of the Argentine output, should arouse to action the president of that republic, Hipolito Irigoyen, a man of practical sense, whatever we may think of his politics. He is not likely to overlook an opportunity for the improvement of his country when the proper course is made convincingly clear to him. For the sake of any who may be inclined to let the bad impressions created by Mexico influence their opinions of her well-behaved sisters in South America, we may point out that the Argentine government, to all appearances, has become as stable as our own. That involves progress in the arts and in the making of rational laws. The criticism offered by Mr. Winchell does not mean that the Argentine government is illiberal and restrictive in the sense applicable to recent Mexican legislation; it means merely that a great pastoral and agricultural people, blessed with rich pampas lying close to the sea, while their minerals are hidden in the remote western mountains, necessarily developed first the accessible riches, and that they have not awakened to the reality of the opportunities for the production of metals. The same course of tardy development characterized the United States. Prior to 1866 there was no Federal mining law on our statute books, and the one adopted in that year was slipped through Congress as a rider on a ditch-law. It is interesting to be assured, by so trustworthy an authority as Mr. Winchell, of the existence of these virgin resources in a country that has passed through the revolutionary measles and whooping-cough to mature healthiness. Favorable legislation will unlock the Argentine treasures in due season.

RUSSIA will need a stable government before any mining laws can be effective. Mr. Winchell's recommendations were made when the Kerensky administration was in the saddle and, it was hoped, so firmly as to be able to ride the storm of revolution. We have not always agreed with Mr. Winchell as to the advisability or otherwise of changing our own mining laws, but that does not prove necessarily that his ideas are wrong. What he says to the Ministry of Commerce at Petrograd concerning the American law of mining is well expressed

and to the point. His suggestions are wise, particularly as to the need for simplicity and uniformity in the proposed regulations; also for the withholding of mineral land from persons or corporations unable or unwilling to develop them, that is, to discourage the speculative holding, or 'shepherding' of claims, as they call it in Australia. Likewise he places emphasis on the desirability of free markets and the absence of vexatious restrictions to operation. He refers to the regulation compelling foreign companies to employ Russian engineers as managers. This has proved a hindrance, rather than a help, in most cases, causing a duplication and conflict of management not at all favorable to profitable enterprise. It would be better to leave the engagement of Russian engineers to the discretion of the operating companies, which would find it useful, in more senses than one, to employ some of the many capable technical men now available among the Russians themselves, but the delegation of supreme local authority to a person nominated by anybody but the board of directors only works for trouble. This has been one of the drawbacks to operating in Russia, and we hope to see it adjusted in a friendly manner for the benefit of all concerned. Meanwhile the many capitalists and engineers interested in Russian mining, and anxious to participate in the exploitation of Russian mineral resources, must possess their souls in patience. No business is possible until sane government has been restored.

ON another page we publish a review of operations during the fourth quarter of the past year in the zinc-lead region that extends over parts of Kansas, Oklahoma, and Missouri, to which we have ventured to give the name of Komselter. Whether this convenient name will prove acceptable to those most nearly concerned, we do not know yet. It will be noted that the mining of zinc deposits, containing lead in proportions varying from a mere impurity to an important by-product, has spread south-westward from Joplin to Picher, and then nearly northward to Crestline, transgressing the borders of three States. Our correspondent, Mr. Otto Ruhl, has long been identified with the Joplin mining industry and is especially qualified to write on the important developments in that part of the country. He will not be offended if we mention the fact that we had to correct his use of the term 'ore' in order not to confuse those of our readers that are unfamiliar with the local terminology. It is the custom at Joplin and its tributary mining communities to use the word 'ore' to signify 'concentrate,' although the same word is also applied to mill-feed or crude ore as it comes from the mine. The significant quotation on the local market is the price for 'ore,' which means a concentrate containing 60% zinc. Other local terms include 'dirt' for mill-feed and 'chats' for a jig-product that needs re-grinding to liberate particles of blende. To these there is less objection because at least they will not be taken to signify something quite different, but to speak of a concentrate as 'ore' is

about as silly as the custom, in Gilpin county, Colorado, of giving the name of 'tailings' to the pyritic concentrate sent from the mill to the smelter, or the Lake Superior habit of calling copper ore 'rock.' The use of such self-contradictory terms may not confuse residents in the district, but it makes for confusion when they undertake to give information to those outside, and it is objectionable in a broadly basic way because it stultifies the language of technology. Now that the zinc region—not 'district'—of Kongsfelter is attracting the attention of operators and engineers all over the country, it would be well to use terms that everybody will understand.

Peace Talk

The new year opens with talk of peace sufficiently serious to test the morale of the Allies. The idea of peace is heavenly. None but a criminal lunatic would wish to prolong the War by one day, provided the purpose of our fighting were fulfilled. That proviso is the crux of the matter. Our purpose is to check the military aggression of a government and a people that have gone mad in an intensive effort to dominate the world and that, in making the effort, have reverted to methods of warfare that shame civilization. We fight to restore the world to sanity and orderly living; that can be assured only when the aggressor is defeated and so hurt by his attempt that he never will be able to make another effort of the same kind. This War is a pitiful tragedy, but there is a worse possible, namely, that the War shall have been in vain, that thousands of young lives shall have been sacrificed only to give Germany an interval of recuperation for another preparation before she tries again to do what she nearly succeeded in doing the first time. There must be no second time. The three years of the present struggle have seen the invention and development of death-dealing instruments and methods at a rate so rapid as to indicate that if the Prussian machine were granted twenty years of peace for a second preparation it could fashion weapons of war that would simply blight the earth like a collision with a comet. The present calamity must be the means of preventing a greater catastrophe. If we endure the horrors of this war, with all its calls for sacrifice of life and happiness, if we face a continuance of the bitter struggle, it is with the determined purpose that this shall be the last of such wars. From the achievement of that purpose we shall not be diverted by the poisonous gas of German propaganda nor by the delirious drivel of the Russian anarchists. The horror of war is impressed upon us; we want to end it and to make the guilty breaker of the peace so sorry that he too will be deterred from another outbreak. Those that have seen the shambles of the battlefield and even those that have read the realistic descriptions, particularly by French writers, will be in agreement that to say that war is inevitable is to utter a blasphemy against the human spirit. It shall not be inevitable; it must be made impossible.

The Affairs of the Institute

An amendment to the constitution of the American Institute of Mining Engineers, with a view to a closer definition of the qualifications for membership, has been proposed and is now to be the subject of a vote. It has long been felt that the Institute suffered from including a number of persons to whom the terms 'engineer,' 'metallurgist,' or 'geologist' were not correctly applicable. This injured the status of the organization and diminished its professional solidarity. Therefore the proposed restrictions, all reasonable and moderate, will be welcomed. Besides restricting the election to membership it is proposed to create a class of 'associates,' to be qualified by "interest in, or connection with, mining, geology, metallurgy, or chemistry." This, at first sight, may seem to be so vague as to perpetuate the worst features of the nondescript membership to correct which the latest constitutional amendment has been proposed. The natural fear of a loyal member of the Institute would be that this 'associateship' may open the doors to non-professional persons without technical training and allied rather to the promotion of mining schemes than to the operation of mines. We understand, however, that this danger has not been overlooked, and that ample protection against it is assured by the scrutiny to which every candidate's name is exposed by the Committee on Membership, a committee that is doing yeoman service. The aim is to make the Institute thoroughly representative of all the respectable and worthy elements in the diverse personnel of the mining industry and yet to restrict full membership to those taking a responsible part in its technical work. This it is expected to accomplish satisfactorily by having both 'associates' and 'members.' During the last five years the additions to membership have been 433, 921, 553, 750, and 1005, the last figure, however, not including any elected after December 15, 1917. Thus 3662 have joined the Institute in the five years, proving the vitality of the organization and the energy of the Membership Committee, the chairman of which is our former associate, Mr. Thomas T. Read. The big gain has been made, with few exceptions, without lowering the standard of past membership. Nor do we see any immediate danger of lowering that average, even after the class of 'associates' has been created, because as much care will be taken in electing the latter as was taken formerly—say, ten years ago—in the election to full membership. The only danger we can see, as a consequence of a big addition of names, is that of straining the finances of the Institute by the publication of papers and volumes that cost more than the annual dues. Less quantity and better quality, a smaller mass of material and closer editing, are needed; and these we shall expect now that Mr. E. K. Judd has been appointed editor of the Transactions. On the whole, even a somewhat detached critic must allow that the management of the Institute during recent years has been such as to inspire confidence.

A Nationalized Railway System

President Wilson has followed the recommendation made by the Federal Trade Commission last June in taking the railroads under Government control. The suggestion at that time was regarded in some quarters, particularly in railroad quarters, as premature. No careful observer could fail to be struck with the fact that a great and peculiar hush fell upon the daily press of America so far as this topic was concerned immediately after the printing of the initial dispatch, which said simply that the Federal Trade Commission had formally advised Congress that the transportation systems of the country, by rail and by water, should be "pooled and operated on Government account, under the President, . . . as a unit, the owning corporations being paid a just and fair compensation." It will be seen how literally the President has carried out the plan advocated by this competent Commission to whom it had become clear, after less than three months of confusion following the declaration of war, that the common carriers, as then constituted, were unable to cope with the national crisis. The succeeding six months have added force to that conclusion. The nation has lost time in military preparation through lack of co-ordination in the transportation service, and the people at large have suffered extreme inconvenience and enormous increases in the costs of doing business over and above the rising prices produced by other economic difficulties. While efficiency would have been gained by prompt action last June, it must be conceded that the trial which is now to be made of Government administration of the railroads will meet with less hostile criticism in consequence of the opportunity given by the President to test the ability of the railroad managers to meet the crisis by themselves. Furthermore, Government aid was afforded them through a committee of practical railroad men whose purpose was to facilitate an effective co-operation under the system of private ownership and control, but in the end it became apparent to the whole country that the net result had been failure. The public therefore accepts the decision of the President with feelings of relief and confidence.

The significance of the step is enormous. Although not directly involving Government ownership it does mean the nationalization of the railway system, and many Congressmen have said that the continuance of Government control for all time depends entirely upon the success attending this experiment. If necessary for the welfare of the nation at a moment when inefficiency dare not be tolerated, it will be logical to ask why public business should be subjected again to demonstrated wastefulness and inefficiency in times of peace. If the War is to bring any great and lasting benefit it must be found in the amelioration of the conditions of human life, and the pivotal question around which revolve the social struggles that have disturbed the world since the growth of the factory system is that of reducing the

hardships of gaining a proper livelihood. Economy in the distribution of commodities is of the utmost importance in planning to alleviate the burdens that press upon the people. In the first months after we entered the War it became evident that the two largest factors in the high cost of living were the evils of profiteering and the inefficiency of transportation. The Government unhesitatingly grappled with the first of these so as to inspire confidence that the middleman will be regulated within another year in such manner as to perform a useful function as a public servant; and now the solution of the transportation problem is undertaken by a master-stroke that promises long-needed relief. It is doubtful if the owners of railway stocks and bonds will consent to have their properties returned after the War to the control of financiers and speculators who would manipulate them for narrowly selfish purposes as they were accustomed to do in the past.

The ownership of nearly one-third of the railroads of the world has already been vested in the governments of the respective countries where they operate. In the British dominions 55% of the mileage is so controlled, and the entire 24,000 miles of railroad in Great Britain itself is temporarily and successfully administered by a Royal Commission. The action of President Wilson affects 265,218 miles of railroad in the United States, making a total of 502,228 out of a world-mileage of 713,120 now operated as public utilities. The time has gone when we need fear political graft and perfunctory service in the administration of nationally controlled enterprises. The Post-Office is a shining example of efficiency and economy. The Panama Canal has afforded another instructive object lesson, enlarging the confidence in Government ownership and control that had been created by such beneficent projects as that of the Sault Sainte Marie locks and canal, which have made possible the great expansion of our iron and steel industry. Government work today is conducted on business principles, for civil service reform has spoiled the larger opportunities for private graft. Railroad employees will pass under similar rules, affording them protection greater than any they can secure through the costly mechanism of labor organizations. They recognize already the advantages flowing from their new status as Government employees, in consequence of the announcement that the exorbitant salaries of the high officials are to be trimmed down, thus enabling higher remuneration to be offered to the humbler workers. It is evident that the salaries paid to senators, departmental heads, bureau chiefs, and other responsible officers of the Government, will constitute a measure of the stipend appropriate for the managers of the railroad system. It is perfectly understood that the princely rewards distributed among railway officials have been in recognition of special ability in aggressive competition, in financial manipulation, and in the control of politics and legislation, rather than for services in the routine of practical operation. Under Government control the need for such qualifications instantly

disappears, and incidentally one cause of political corruption thereby will be eliminated. The great organizations maintained for the solicitation of patronage will now be unnecessary, and many of the minor competing lines can be consolidated, not only insuring better service, but relieving them from an unnecessary burden of administrative expense. The wastefulness of separate terminals will be greatly reduced; the luxurious and half-filled passenger trains will be adjusted to the actual needs of the traveling public; the tourist business, especially during the continuance of the War, will no longer embarrass more necessary service. Under the old system many of these extravagances were unavoidable. To a large extent the duplication of roads and terminals, and the consequent overhead cost, were the only means that offered escape from crushing monopoly. The profligacy of the system stands out in strong relief as soon as we contemplate a single national system operated for the welfare of the whole people. Major Smith W. Brookhart, one of the best-known railway statisticians in the country, recently estimated that Government ownership would save \$400,000,000 per year through elimination of competitive waste, and \$500,000,000 in interest upon funds required for betterment because of superior Government credit. Major Brookhart's figure for the saving to be made by abolishing competition is regarded as conservative. No less capable a witness than C. P. Huntington affirmed some years ago that the competitive waste in New York City alone amounted to \$100,000,000 annually. It is likely that the consolidation now consummated will effect economies in excess of a billion dollars per year, quite apart from the advantages of effective assembly of military supplies and the cheaper and more systematic distribution of the necessities of life throughout the United States. On the outbreak of hostilities in Europe the railroad managers, professing not to realize the inevitable expansion of business that would ensue, took a pessimistic view of the industrial future of the United States. At a moment when orders for equipment, barely adequate for the needs of normal traffic, might have been placed at most advantageous prices, they curtailed the outlay for maintenance and improvement. A few months later, when the flood of war-orders from England and France began to inundate our manufacturing the railroads proved unequal to the task of handling the business successfully, and operating costs were increased by the necessity for ordering rolling-stock and other supplies at war-prices. Under Government control it would be possible to take advantage of periods of market depression to provide needed equipment, and this would act as a stabilizer of industrial conditions. Already the Administration has suggested the necessity for providing money to make good the shortage of rolling-stock. All the funds that are needed can be secured on guaranteed bonds at 4%, where privately owned roads would have to pay from 5 to 6%. Moreover, it is understood that the Government will seek authority to purchase such new securities, thereby becoming a creditor

and looking toward permanent control of our national transportation system. The real owners of the railroads long have been the general public. They now find themselves protected as never before, through the Government guarantee of dividends based upon the average return for the last three years. The effect on the minds of the people has been registered by the sudden rise of quotations on railway stocks. No step that President Wilson has taken has met with more popular approval than the nationalization of the American railroads. It makes for unity of effort in winning the War, for higher efficiency in our whole industrial system, and for reduction in the cost of everything that enters into the life of the people.

Gold and Credit

Although the threat to discriminate against freightage for gold mines has been withdrawn, it will be well for every thoughtful citizen to be on his guard against an economic heresy that would do much worse than threaten the welfare of a part of our mining industry—it would endanger our solvency as a nation. The net gain of gold to the United States from August 1, 1914—the day the War began—to November 16, 1917, is stated officially to be \$1,082,212,000. This gain is impressive, but it is small compared with the indebtedness being incurred at a growing rate by the Government for the purposes of the War. The expenditure in one year is twenty times as much as the value of the gold accumulated in three years. It is no wonder that the use of gold coins for Christmas presents was discouraged by those in authority nor that an embargo has been placed upon the export of this basic commodity. We must keep our gold where it can perform the greater service, and we should intensify the mining of the ore that will yield more of it. We shall need it, if we are to emerge financially safe out of the morass of international credits. The expansion of bank-credits caused by the flotation of huge government loans in Europe and in this country since the War began is tending to produce world-wide inflation, such inflation as is inevitable when a government borrows faster than its people are able to save. As Mr. Adolf C. Miller, of the Federal Reserve Board, has indicated, the rise in prices of all commodities is due to the fact that the purchasing media—bonds, notes, and other forms of credit—are being produced faster than the commodities themselves. "When the supply of currency and credit in its increase outruns the supply of purchasable goods, the price of goods must rise," says Mr. Miller. That is sound doctrine. Let us see now where it leads us. The normal, conservative, credit-expanding power of gold is usually taken at about the ratio of seven to one, that is, the gold reserve of the United States, now estimated at \$3,089,000,000, is good for a volume of adequately secured commercial paper amounting to a little more than 21 billions of dollars. Moreover, the expansive power of the British gold reserve is also being utilized in this country through the fiscal agents of Great Britain, thus

adding to the volume of credits available, while exchange is protected through daily purchases of surplus bills drawn against London, thus stabilizing the value of the pound sterling. In effect, the British banking system has become unified with that of the United States, and other allied countries are doing the same. Accordingly no paralysis of credit is in sight at present, and our resources have not yet been over-strained. The available inter-allied credit-limit is not far short of 40 billions of dollars. On the other hand, the increase in the nominal value of commodities represents a shrinkage of purchasing power, so that the commodity-volume to which the expanded credits apply has actually cut our financial resources nearly in half, viewed with relation to supplying the needs of our own country and of our Allies. This explains what Mr. Miller meant when he pointed out the disproportionate increase of credit-paper over the corresponding actual volume of commodity-output. The ultimate effect would be disastrous were prices to fall at the end of the War. That would mean ruinous liquidation. Apparently the stability of business depends in no small degree upon maintaining the scale of prices and wages established under the stimulus of the wild speculation that followed the receipt of big war-orders from Europe in 1915 and 1916. Had our political leaders foreseen, as did a few of our broad-minded financiers and political economists, that this was our war from the moment when the Germans, frustrated at the Marne, began to dig themselves in for a long and stubborn contest, we would not have disturbed the financial structure of America and the world by proceeding to exploit the nations then involved in the struggle against Prussian aggression. The mob of commission men had much to do with adding to the enormous cost of supplies in the earlier period of the War, but, after this evil had been corrected in part, the manufacturers continued to quote prices out of reason, as the soaring quotations of industrial stocks accurately recorded at the time. It is not to be expected that the laboring man and the producer of raw materials will consent to receive the pay corresponding to periods of normal business when the evidence of profits that can multiply the value of stocks many times over is presented daily to him in the stock-exchange reports. Failure to realize our grave responsibility at the right moment, coupled with our persistence in squeezing the last dollar we could get from the nations that were then fighting the battles that protected us from the Prussian menace, has precipitated a new difficulty that calls for the wisest statesmanship and the soundest finance. Inflation of prices has resulted, and the world must not only adopt these fictitious values, but may need to maintain them for an indefinite period, in order to avert collapse. Our dollar is no longer the dollar of 1914; it is about 58 cents as compared with the purchasing power of the dollar of that period. The dollar of today is an altered monetary measure, and it will require more gold to cover the transactions of the future in equal quantities of wheat and corn and meat than it did in the past. To

talk of restricting the accumulation of a gold reserve at a time when the purchasing power of the dollar has shrunk one-half is to limit the volume of credit to a point that will prove insufficient for the growth of commerce. Fortunately Great Britain and the United States have a corrective in their resources of gold-bearing ore. Between them they control directly 80% of the world's annual production of that metal, and indirectly at least 10% more. The gold production of the world is \$150,000,000—not much in these days of billion-dollar loans, but enough to stiffen the base on which a vast system of credit is reared. Of the world's silver the British dominions produce 30,000,000 ounces and the United States 75,000,000 ounces, out of a world's total of 177,000,000. Indirectly the Allies control the output of at least 50,000,000 ounces more, so that 155,000,000 ounces, worth now about that many dollars, is available annually for maintaining the basis of credit. Thus the two English-speaking Allies, by their own mineral resources and the enterprise of their citizens in other regions, control 90% of the precious-metal production forming the hard bottom of international credit. The enemy countries—Germany and her vassals—cannot place their hands upon more than 2% of the gold and silver annually produced. This is a factor of prime importance at this juncture in the world's history. It represents a decisive economic advantage, if properly utilized. In conjunction with the reserves on hand, it constitutes an adequate foundation for a complete and well-balanced industrial organization, outside the confines of any Teutonic hegemony. We can suffer the Hun to rage within the barbed-wire entanglements that now fence about his empire of wrath. The nations outside possess nearly five-sixths of the total gold and silver that is so necessary for universal credit and exchange. This is exclusive of the reserves that the old regime left in the State Bank of Russia. Despite the improvident exaggeration of prices that was induced largely by a scramble for sudden wealth through war-contracts, and which, like a noxious germ, has developed its own toxin in the form of an attenuated dollar, the exterior nations are prepared, both industrially and financially, for continued growth as a world apart. Even the abstraction of materials for belligerent uses may not defeat the natural expansion of industry when it is considered that all elements are available, and in a quantity greater than served the needs of commerce before Germany and her *ames damnées* became barred from intercourse with the champions of freedom. Problems of extremest gravity, no doubt we have; conservative financing must guide us in meeting the changed conditions brought on by top-heavy governmental burdens; but the spectacle of a world provided with all the essentials, so that the maintenance of commercial equilibrium does not require the Central Powers, is a pleasing thought as we step into the New Year. It suggests an adjustment between the free nations of the world that will ease the economic hardships that have been so pronounced at the beginning of the struggle.

DISCUSSION

Water in Stamp-Milling

The Editor:

Sir—There are many and varying factors that govern the ratio of water to ore in stamp-milling. Recently there came to my attention an example of present practice on the Mother Lode, California.

Crushing with 950-lb. stamps, through a 20-mesh screen, at 110 drops per minute, a $7\frac{1}{2}$ -in. drop, and a low discharge, the output per stamp is 7.5 tons per 24 hours. The ratio of water to ore is 2.4:1. The pulp flows over amalgamating plates having a fall of one inch to the foot, thence to tables.

One would expect with an output of 7.5 tons per stamp per 24 hours a water-ratio approximating 5 or 6 per ton of ore. Seeing a high crushing-duty was desired, the question naturally arises why so little water is employed, water being plentiful. It appears beyond controversy that, within limits, an increased water-supply gives an increased output, by liberating the particles when ground. Would an increase of water in this instance have added to the already high stamp-duty?

In modern milling practice, using coarse crushing, a water-ratio of at least 6:1 appears necessary to wash rapidly the coarser particles through the screen. I infer, therefore, since water is the vehicle of discharge, that coarse crushing requires a higher water-ratio than fine crushing. The point I wish to bring out is this: is not the tonnage crushed high relative to the water used, and would the output not be further increased by an addition of water?

Possibly other workers on the Mother Lode may afford further data.

Scotch Philosophy and the Lead-Smelters

The Editor:

Sir—The greatest glory of Scotland, one of the highest honors that could be possessed by any nation, is found in the achievements of those transcendent intellects which adorned and embellished her literature in the latter part of the 18th century. During that period there sprang forth from her bleak and misty hills upon an astonished world the amazing and comprehensive conceptions of Adam Smith, the clear and skeptical logic of Hume, the profound and far-reaching discoveries of Black. Adam Smith produced order from the chaos of the collective actions of men. His 'Wealth of Nations'

and the ideas contained in that monumental work transformed the English policy of trade. Hume, with unparalleled lucidity, tore the mask from superstition and cant, and lastly Black made his generalizations on the existence and behavior of latent heat. Lesser lights in the constellation of Scottish greatness might be cited, but the object here is not to exalt Scotland, but to justify a system of thought that appears to have been transplanted to America, and to have further justified itself by success in American industrial fields, as well as in the Scotch philosophical world.

It is not my purpose to tire the reader with prolix philosophical distinctions between the various methods of reasoning. There are, however, two sharply defined systems of thought, one being known as the 'inductive' method, and the other as the 'deductive.' The inductive was, and probably is, the typical English method. In this system great stress was laid upon experimentation, and the proving of principles by a multitude of facts. The deductive method, on the other hand, by great flights of the imagination, established its principles and proceeded by 'deduction' to arrive at results without the laborious efforts required by the opposite system.

Perhaps no field of American industry displays a more profound knowledge, or greater skill in the application of the principles that underlaid the work of the Scotch philosophers, than the one occupied by the lead-smelters. A thorough study of the typical settlement sheet displays an intricate—indeed, a dazzling and incomprehensible—knowledge of deductive methods. The men who outlined the process of ore-buying, of which a settlement sheet represents merely a summary, show a rare skill, which for general scope compares favorably with Adam Smith, and for finish and touch, was never excelled by the delicate efforts of Hume. An instance to the point is where the smelters make a deduction of 1% for moisture regardless of any efforts to prove inductively that it is there. In fact, the magnificent sweep of their intellects steps over the presence of such a small item. It is sufficient for these able men that they make a fitting and proper application of their basic principles.

Their next step is to ascertain what percentage of lead is contained in the ore. This they first firmly establish, ignoring the old fire-assay, which, of course, is low. By latter-day methods the amount of lead in the ore is determined. Once this point has been reached, deduction philosophically steps in and proves incontrovertibly that although the lead is not absent, neither is it all present, and no matter what is there, there are two units less

than whatever it may be. Thus is the antiquated fire-assay reconciled to its more modern successor by a clever adjustment of differences that, in the end, leaves everything pretty much as it was in the beginning, and obviates any confusion that might have resulted from the introduction of the later method.

The reader's attention should now be concentrated with particular intensity upon the next step. Here, unless great care be taken, one will be apt to jump to the conclusion that deductive methods are being ignored, as with apparent abandon they yield the seller 90% that may exist at this stage of the deductions. Reflection, however, will show that the smelter is entirely consistent and that a little thought on the part of the reader, without further argument, will prove that precisely the same result may be reached by deductively abstracting 10% from the amount existing at the stage marked by the beginning of this paragraph.

We now come to the master-stroke, the point where the deductive process becomes overwhelming to the mere miner. There is another fine touch here, a neat and clever distinction, and at bottom a profound appreciation of the difference between scientific and empirical knowledge. If lead is selling at five cents per pound, and the smelter usually determines whether it is or not, one and one-quarter cents is deducted presumably for shipping, refining, and selling expense. After the price has passed the five-cent mark, one-quarter of a cent is deducted for each cent paid over five cents. Now, without reflection, the average person will no doubt consider that the deduction before the five-cent price, and the deduction after the five-cent price were one and the same thing, and that after all a 25% deduction would attain the same result as the more complicated system. It is manifest, however, without recourse to any fine reasoning, that the cost of refining, shipping, and selling does not vary with the market-price of the lead, and that the smelters must be guaranteed a reasonable compensation for this service independent of the price of the product. Here for once we find a deduction that is not the result of deductive reasoning. It should be noted, nevertheless, that the deduction, although not deductive, cannot be said to be inductive, as the facts upon which this deduction has been based have not been established as actually existing. In other words, the smelter has not proved that the costs are actually one and one-quarter cents, but might be any figure, say one-half a cent, one cent, or even two and one-half cents. After the price has passed five cents, however, the smelters come again under the unrestricted sway of their deductive principles. One-quarter of a cent per pound here means 25% of the value of the lead, a splendid stroke as the most enthusiastic inductive philosopher would be obliged to admit.

For money the Americans have been branded as mere money-makers, dollar-chasers, and Mammon-worshippers. We were held up to view as a people glorying in vain shows of power and wealth, sensual ambitions, and all forms of material success. The refinements and intel-

lectuality of Europe were supposed to be wanting in our lives. We were a nation devoid of ideals, uncultured, uncouth, and altogether beneath the more refined civilization of the older nations. But is this found to be true? Have we not, on the contrary, discovered that some of our biggest business men are steeped in the learning and wisdom of by-gone days? Is not every action found to be guided by deep-set principles? Acts, heretofore inscrutable, have become understandable. What previously has appeared capricious is suddenly shown to be governed by reason and logic; and as a great scientist will, from a multitude of apparently unrelated and chaotic facts, formulate a theory that will disclose an almost divine order and system, in the place of a supposed disorder and confusion, so do we see here, through an understanding of the great Scotch philosophers, that the apparently capricious and arbitrary deductions of the smelters are only what a philosophical mind should reasonably expect.

Geology of the Success Mine

The Editor:

Sir—There has been considerable controversy as to priority of the ore and monzonite (locally known as granite and will be so designated hereafter) in the Success mine, in the Coeur d'Alene. F. L. Ransome of the U. S. Geological Survey, in Professional Paper 62, took the view that the granite was there first. Oscar H. Hershey, after an extensive examination, concluded that the granite was post-mineral, and so expressed himself in a paper in the MINING AND SCIENTIFIC PRESS about two years ago. Joseph B. Umpleby followed this with an examination about a year ago and confirmed Mr. Ransome. Mr. Umpleby based his conclusions upon the replacement of the granite by ore, which he determined by sections under the microscope. Not being a geologist I am unfamiliar with the proper weight to be attached to microscopic work, but, from a physical point of view, there always appeared to me to be a doubt, since, in all specimens of granite containing stringers of ore, these are invariably a continuation of quartzite stringers partly replaced, and the question always comes to my mind whether these stringers might not be a replacement of quartzite stringers in the granite, the quartzite having been entirely replaced. I have, however, recently obtained a specimen of a nodule of granite entirely surrounded by ore. A chunk of apparently solid ore was broken open and found to contain a nodule of granite nearly as large as a hen's egg. It was taken from a spot where numerous stringers of granite extended into the ore. The neck of granite which connected this nodule to the parent body must have been wholly replaced by ore. This seems to me to give conclusive proof that the granite was there first. If I am mistaken I am willing to be corrected.

Sunset, Idaho, December 10.

THE EDITH AND THE CONCRETE SHAFTS, AND MR. DOUGLAS'S HOUSE.

The Story of the U. V. X. Bonanza—I

By T. A. RICKARD

The most remarkable discovery of ore made in recent years is that which has given more than local fame to the United Verde Extension mine, at Jerome, Arizona. Jerome¹ is in Yavapai county and 25 miles north-east of Prescott, formerly the capital of Arizona and always an important mining centre. See map, Fig. 1. For about forty years Jerome has been identified with the United Verde mine, although the first claim² in the district was located as early as 1876. The ground now included in the United Verde is said to have been worked for silver ore between 1880 and 1885. No silver-reduction plant, however, was erected. The ore was smelted for copper as early as 1883, when a 42-inch water-jacket furnace was erected. The president of the company that operated the United Verde at that time was F. A. Tritle, formerly governor of Arizona, and still earlier the manager of the Yellow Jacket mine on the Comstock lode. The secretary and treasurer of the company was Eugene Jerome, of New York, and it was after him that the town of Jerome was named. This company produced a considerable quantity of copper, in the form of black copper and

matte, until 1887, at which time the resources of the mine appeared to be depleted. In 1888 William A. Clark, subsequently Senator from Montana, bought the property and started fresh exploratory work.

In 1884 Mr. Clark was appointed commissioner to represent the State of Montana at the New Orleans exposition. Among the mineral exhibits he noticed some samples of copper ore from the United Verde mine; these interested him because the assays attached to the specimens showed that gold and silver were associated with the copper. In his usual methodical manner he recorded a note on the subject. Returning to Montana, he forgot about it. His mines at Butte, which were highly productive, supplied ore to the Port Orford Copper Co. in New Jersey. When this refinery went into liquidation, in 1886, Mr. Clark was one of the chief creditors. He assumed the control of the refinery and operated it for a year or more. When examining the records he found assays of shipments of ore from the mine in Arizona that had supplied the specimens he had noticed at New Orleans. Thereupon he sent Joseph L. Giroux to examine the United Verde. Mr. Giroux found that the controlling interest in the property was under option to some people represented by James Douglas, so he arranged to have the refusal. Dr. Douglas decided not to exercise his option, because, so I am informed, the lode was spotty; whereupon Mr. Giroux informed Mr. Clark, who came at once, and, after an inspection, purchased 70% of the stock, acquiring most of the remainder in after years. The Senator for Montana had no liking for geologists, he did not retain a geologist on his staff, and he excluded visiting geologists. Therefore he failed to inform himself concerning the geologic structure of the Jerome district, and it remained for the son of Dr.

¹On a map accompanying a paper by the late John F. Blandy on 'The Mining Region Around Prescott, Arizona,' in Vol. XI, Trans. A. I. M. E., the position of Jerome is indicated by the name 'Wade Hampton' and the description 'Copper mines.' This paper was read in February 1883.

²The Verde, so named on account of the green stains of copper, is usually mentioned as the first claim located in the district, but, on inquiry, I find that the Verde was located on May 16, 1886, whereas the Azure (another reference to oxidized copper mineral) Northwestern, Azure Southeastern, Chrome Northwestern, Chrome Southeastern, Eureka, and Wade Hampton claims constituted the earliest group of locations. Of these the first to be recorded was the Chrome Southeastern, on February 19, 1876, by John O. Dougherty and John P. Kelly.

Douglas, as we shall see, to find and develop a mine as rich as the United Verde in the immediately adjacent ground.

In 1892 the United Verde paid its first dividend and shortly thereafter this mine took rank as one of the great copper enterprises of the world. The United Verde has

not permit visitors to inspect his mine, his policy being to exclude operators from the vicinity.

In 1900 a surveyor named J. J. Fisher located a fractional claim out of which grew the enterprise now known as the United Verde Extension. Fisher was not in the employ of Clark; he was a U. S. Deputy Mineral Sur-

FIG. 1. MAP OF ARIZONA, SHOWING POSITION OF JEROME

produced 800,000,000 pounds of copper and is credited with a reserve of ore likely to yield as much more.

During the greater part of its history the Jerome district was a 'one-mine' camp. It could boast only one noteworthy enterprise. No extension of the United Verde orebodies was found, mainly because a master-fault with a big throw spoiled the chance not only of tracing the ore-zone but of exploring the adjacent claims, except at a prohibitive cost. Senator Clark did

veyor and in that capacity had been employed occasionally by Clark and by others in the district. At the time when he discovered this fraction of vacant ground he was surveying for the late George W. Hull, a successful miner, merchant, and State legislator, who had lived at Jerome for many years and was keenly alive to the importance of tracing the United Verde ore-zone into outside ground. Fisher found a fraction covering less than an acre, between the March claim, belonging to Hull,

and the United Verde property. He located it under the name of the Little Daisy and persuaded L. E. Whicher to take an option on the property, the latter selling enough stock to start the sinking of a shaft, under the superintendency of E. A. Powers. That was in 1900. This shaft was sunk 300 ft. through the lava and limestone covering the ore-bearing formation, which is schist. At about 100 ft. the shaft penetrated ground that

In order, however, to explain the true relation of Fisher's enterprise to that of Hull, it is necessary to record the vicissitudes of early exploration and promotion. In 1899 the first company to prospect this area was organized by Hull; it was called the United Verde Extension Gold, Silver & Copper Mining Co.; it became known as the U. V. X. and its successors have had the various modifications of the name abbreviated likewise.

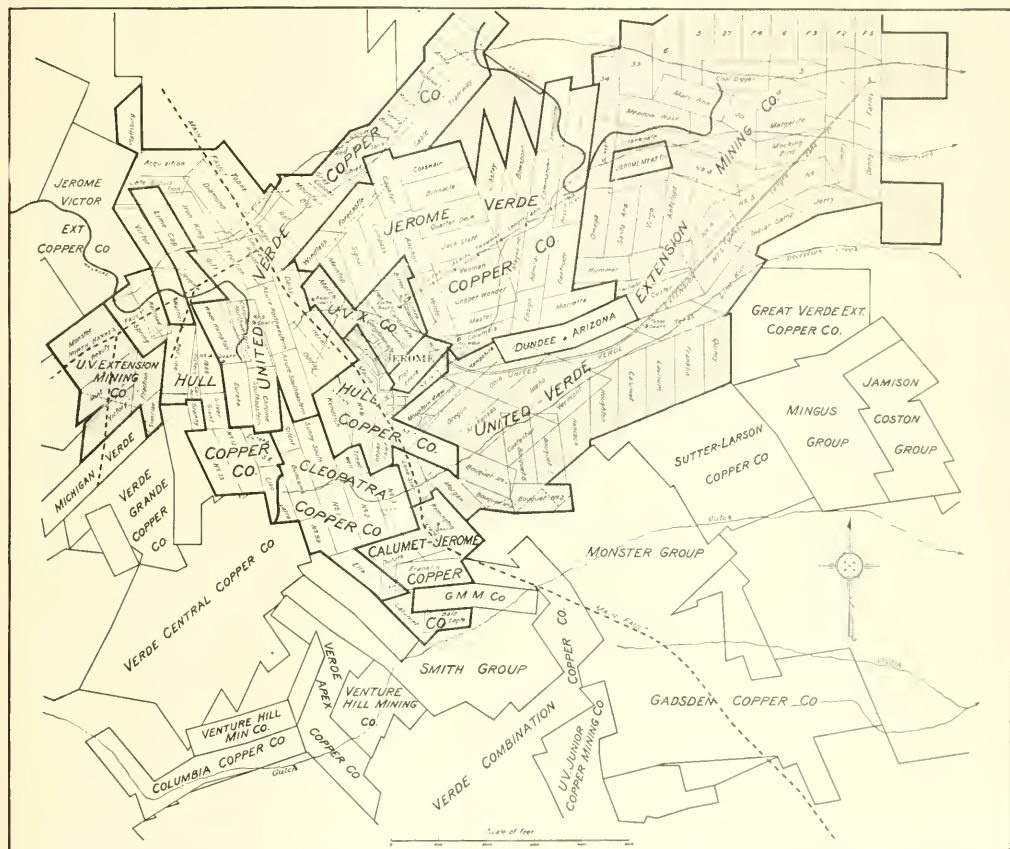

FIG. 2. PLAN OF MINING CLAIMS IN THE CENTRAL PART OF THE JEROME DISTRICT. THE UNITED VERDE EXTENSION PROPERTY IS SHADED

showed signs of ore, but nothing of value was discovered in the drifts and in 1901 operations ceased. The enterprise seemed to be blighted by the fact that the most promising workings were within a hundred feet of the March claim, owned by Hull, as already stated. Fisher found it difficult to obtain any additional financial aid and the Little Daisy remained idle until Mr. Whicher acquired the claim for 5000 shares of a company that he organized in 1906, and shortly thereafter the shaft was deepened to 800 ft., again under Fisher's direction. He unfortunately did not live to see his hopes fulfilled, for he died in 1911.

Throughout Arizona the mine is known by its initials. This first company controlled a dozen claims, including the territory directly west of the United Verde, with the ground north and south, so as to enclose Senator Clark's property on three sides. This company was capitalized for 300,000 shares of \$10 each, and was organized under the laws of Arizona. In March 1899 Louis E. Whicher, of Schotfield, Whicher & Co., at Boston, became interested in the promotion of the company at the instance of the late Franklin Farrell and associates. At the last moment Farrell had some disagreement with his associates and withdrew, but Whicher proceeded with the business, the

result being that he and his clients acquired 190,000 shares, Hull retaining 110,000 shares. Mr. Whicher became the largest individual shareholder, his holdings representing \$100,000, which also was the amount of cash available for exploratory work. A shaft was sunk on the claim called '1888' (See map, Fig. 2), this shaft being within a stone's throw of the United Verde shaft. Mr. Whicher obtained the professional advice of a competent engineer, Milton F. Johnson, and was encouraged in the belief that if there were any ore to be found outside the United Verde, it would be east of that property. At this time, in 1900, Fisher had located the Little Daisy fraction, and was trying to get money for prospecting. Whicher obtained an option on the Little Daisy for \$50,000 and sank a shaft upon it to 300 ft., of which 125 ft. passed through oxidized coppery rock, too low-grade to be ore, but so promising that Mr. Whicher was prompted thereby to begin negotiations with Hull for the acquisition of the claims adjoining the Little Daisy, namely the March, Conglomerate, Iron Carbonate, and Bitter Creek locations. This transaction followed upon a curious episode. In 1900 Hull had begun divorce proceedings at Providence, and was arrested on the train, while passing through this town, for having sworn incorrectly that he was a resident of the State of Rhode Island. At this juncture he appealed to Whicher to help him out of his predicament; Whicher took Hull to Boyd B. Jones, of Boston, then District Attorney of Massachusetts, and by his aid Hull was extricated from his entanglement. The immediate sequel was that Hull, now in a docile state of mind, made a trade with Whicher, whereby Hull transferred his 110,000 shares to the U. V. X. company and also deeded the four claims above-mentioned, in exchange for the properties originally owned by the U. V. X. company. These four claims had been incorporated under the name of the King Development Co. In return, the U. V. X. company transferred to Hull all the various claims that it owned around the United Verde property. By this exchange the U. V. X. company became the owner of Hull's four claims and, shortly thereafter, of the Little Daisy fraction, which Whicher acquired for the company from Fisher for 5000 shares of U. V. X. stock.

These deals having been consummated, the U. V. X. company was re-organized, in 1902, under the laws of Maine, but with the same capitalization, namely, 300,000 shares of \$10 each. In 1910 another re-organization was effected, this time under the laws of Delaware, the capital being increased to 400,000 shares of the same par value.

Meanwhile Mr. Whicher persisted in his prospecting. The Little Daisy shaft was sunk to 800 ft., and a search for ore was made under Fisher's direction. From 1907 to 1911 C. C. Burger was consulting engineer to the company and showed sustained confidence in the outcome of the exploratory work. In March 1911, Mr. Whicher arranged for an examination by R. M. Atwater, Jr., who reported favorably. In his report, which is before me as I write, Mr. Atwater stated that his experience led

him "to expect high-grade copper orebodies at or near the water-level." He concluded by stating: "I believe the chances of finding valuable orebodies are excellent." This is dated April 8, 1911. At the same time Mr. Burger reported the finding of ore assaying 2.6 to 3.1% copper, with \$2 in precious metals, in a winze then 65 ft. below the 800-ft. level. The copper was in sulphide form, but it showed signs of leaching. This 'near-ore' looked promising, but a more important find was a patch of 39 to 42% ore cut in an eastern cross-cut from the 700-ft. level. This chalcocite ore was 5 ft. wide and 15 ft. long, averaging 18.7% copper, as stated by Mr. Burger. Along the 800-ft. level a much larger body of low-grade oxidized material had been exposed and its downward persistence was indicated by the winze. Yet the enterprise languished. The finding of the chalcocite patch caused the shares to jump to \$4. It was a mere flash in the pan. Several other experts came to Jerome to make an examination, they reported adversely, and in kindness to them I abstain from giving their names. They accounted for the copper in the schist, particularly in the main east cross-cut from the 800-ft. station, by supposing it to be due to solutions originating in the United Verde orebody. The patch of chalcocite failed to impress them. In the summer of 1911 Whicher interested Theodore Gross and A. Chester Beatty in the venture and on Mr. Beatty's initiative a mining geologist of acknowledged ability inspected the U. V. X., but he reported that the conditions were unfavorable.

Up to this time about \$500,000 had been spent in the search for a real orebody. Fisher had been serving as manager for the U. V. X. company until January 1911, when he was succeeded by Thomas A. Varden, of Butte. Mr. Whicher was president of the company.

In 1908 Major A. J. Pickrell had purchased stock from Fisher and for a time he had served as a director of the company. Through him the U. V. X. was destined to obtain the financial assistance needed to bring the enterprise to fruition. In December 1911, shortly before Fisher died, Major Pickrell wrote to James S. Douglas, urging him to come to Jerome and look into the business. Mr. Douglas is the son of James Douglas, the dean of copper mining in Arizona, long identified with Phelps, Dodge & Co., and with all that is honorable and scientific in the mining industry of the South-West. In April 1893, while James S. Douglas was in charge of the Senator mine, ten miles south of Prescott, he came to Jerome to repair a compressor-shaft, simply because Senator Clark's machine-shop at the United Verde mine was the nearest available. Subsequently he visited Jerome a number of times to see George Hull, and in this way he acquired some familiarity with local conditions. In June 1899 he met Colonel D. P. Bosworth, of Marietta, Ohio, the enthusiastic promoter of the Verde Queen mine, which is on the limestone cap just east of the town of Jerome. The Colonel had uncovered a little carbonate ore in the bed of Bitter creek on the Columbia and Verde claims, the latter an early location covering the ground on which Mr. Douglas's house now stands. Bitter creek crosses

the line of the big fault and collects the drainage of the hillside below the United Verde mine. This property of Colonel Bosworth was re-organized later, becoming the Jerome Verde, now prominent among the prospecting ventures in the district. Bosworth consulted Douglas, who, in this way, obtained some further knowledge concerning the local geology. Upon his arrival at Jerome in December 1911, on the invitation of Pickrell, as already stated, Douglas was shown the workings on the 800-ft. level of the U. V. X., but he was unable to examine the winze or the lower workings, then down to

business, whereupon Major Pickrell again urged the younger Douglas to interest himself in the enterprise—this time successfully.

In the summer of 1912 Mr. Douglas and George E. Tener, of Pittsburgh, took the venture in hand and invited their friends to join them in providing \$225,000 for the development of the property. These two gentlemen decided that it was futile to attempt further search for ore from the bottom of the Fisher winze, but that the prospect justified the sinking of a new shaft at a spot 2000 ft. east of the Little Daisy shaft. Under date of

1200 ft., on account of water. However, what he saw impressed him so favorably that negotiations were commenced, leading to an option. This option was submitted to Phelps, Dodge & Co., whose counsel (William Church Osborn) at New York, disapproved of the transaction on account of some fancied defect in the title, in which supposition he proved to be wrong. The organization of the U. V. X. company and the examination of titles had been placed by Mr. Whicher in the hands of Brandeis, Dunbar & Nutter, the senior member of this firm being Louis D. Brandeis, now a Justice of the U. S. Supreme Court. Dr. James Douglas and his associates were favorably disposed to the deal, but the technical objection of their legal adviser caused them to drop the

August 14, 1912, they sent the following letter to a number of mining engineers, metallurgists, and mine operators:

"George E. Tener and J. S. Douglas have secured an option on 450,000 shares of stock of the United Verde Extension Mining Company.

"The United Verde Extension Mining Co. is capitalized at \$750,000,^a with 1,500,000 shares of a par value of 50 cents each.

"The original stockholders own, in round numbers,

^aThis represented an increase to 1,500,000 shares of 50 cents each, as compared with the former capitalization of 500,000 shares of \$10 each, as covered by the contract between Douglas and Whicher, the president of the company.

400,000 shares, and George E. Tener and J. S. Douglas have an option on 400,000 shares and have paid \$25,000 into the treasury of the company for 50,000 shares.

"500,000 shares will be left in the treasury.

"The option on the 400,000 shares runs to June 15, 1915, and the shares are to be purchased as the Treasurer may require funds for development work, at the discretion of the Board of Directors who will be controlled by Mr. Tener and Mr. Douglas.

"As a commission for services the United Verde Extension Mining Company are to pay Mr. Tener and Mr. Douglas 150,000 shares proportionately as the money is placed in the treasury. A proportion of the stock received by Mr. Tener and Mr. Douglas as commission from the United Verde Extension Mining Company is being used by them for organization purposes, but to comply with the law of the State of Delaware it must be issued to them for services rendered.

"They propose to extend to you the privilege of subscribing for . . . shares at \$0.50 per share, equals \$. . . , this subscription being subject to the call of the Treasurer, Mr. C. P. Sands, at 280 Broadway, New York, who will most likely call for 20% of this amount on close of this subscription list, and the balance as needed, which will probably be at the rate of 20% every three or four months. The Treasurer will forward stock to you as amounts are received in response to each call.

"It is proposed to expend \$25,000 in development work on the present 800-ft. level of the United Verde Extension Mining Company's property at Jerome, and if the results are satisfactory to expend \$200,000 at the rate of about \$10,000 a month, cross-cutting and drifting at that level.

"Mr. Tener and Mr. Douglas are not asking their friends for subscriptions, but believe that their plan for the development of the United Verde Extension Mining Company's property will result in the discovery of valuable orebodies, and in sending you this letter, it has occurred to them that you might consider it a favor to be permitted to join in a speculation which they recommend as such."

I have given this letter verbatim, so that the reader can decide for himself whether it would have caused him to take a share in the gamble, for it was that frankly. The last paragraph makes it clear that the two promoters of the enterprise were not begging for financial assistance. The letter is unlike the ordinary prospectus in that it states the principal conditions plainly and truthfully, without any iridescent touches. It seems to me that my own response—supposing that I were not an editor under a self-imposed obligation not to speculate in mines, in order to conserve my position as an unbiased commentator—would have been guided entirely by my confidence in the integrity of the two promoters and my opinion of their sagacity in such a business. Mr. Tener was known to most of the invited subscribers as an experienced and honorable mine-operator; he was the organizer and one of the directors of the Calumet & Arizona venture, and he had been connected for many years

with the Oliver Mining Co., a big iron enterprise in Minnesota. He lives at Pittsburgh and is the brother of a former Governor of Pennsylvania, John K. Tener. But it is no reflection on him to say that it was mainly on the recognition of Mr. Douglas's good sense and practical experience, plus unquestioned confidence in his good faith, that the money was subscribed promptly.

More than a third of the stock of the company, then reorganized as the United Verde Extension Copper Co., is held in Arizona. James Hoatson, of the Calumet & Arizona Copper Co., visited the prospect and approved the venture cordially. He owns 16,000 shares. George Kingdon, a Cornish mine-captain,⁴ then in charge at Cananea, endorsed it heartily before the new work was commenced. Today he owns 18,000 shares. Among the other subscribers were Charles Briggs, W. H. Brophy, H. Kenyon Burch, Chester A. Congdon, James Douglas, Walter Douglas, John C. Greenway, Thomas Hoatson, Arthur C. James, L. D. Ricketts, John D. Ryan, Casper Schultz, W. D. Thornton, and J. S. Williams, Jr. It will be noted that Mr. Douglas's father and brother both supported him by taking stock. The money was raised by means of five successive calls for \$40,000 each at 50 cents per share, so that with the \$25,000 that Messrs. Douglas and Tener themselves furnished, before they asked their friends to come in, there was \$225,000 available for exploratory work.

In April of the same year an examination of the mine was made by Ira B. Joralemon, mining geologist to the Calumet & Arizona Mining Co. In his report Mr. Joralemon said that he would expect to find good sulphide ore at a moderate depth below the leached and mineralized material on the 800-ft. level. He suggested that "the leached and crushed area in the Little Daisy might be part of a shear-zone, like that in which the great orebodies of Jerome occur. While the result of the work is a gamble, there is chance of finding a mine worthy of being compared with the United Verde." He concluded by stating: "I think the chance is worth taking."

This advice justified a group of men in spending money that they could afford to lose. It confirmed the previous opinions of Messrs. Burger and Atwater. Mr. Joralemon received some shares in part-payment for his report, but took his profit prematurely when they rose to \$6.50. Here I may anticipate by saying that the shares rose to \$45 when the wonderful orebody was uncovered on the 1400-ft. level. Before that consummation was reached, however, several shareholders showed reasonable conservatism, or 'cold feet,' as you will, and sold out almost as soon as they could get back the money they had put in. However, most of the original subscribers held on, becoming rich men, if they were not rich already. Captain Hoatson persuaded a number of his friends in Michigan to buy stock and I doubt not that

⁴Formerly superintendent of the Old Dominion mine, at Globe, and a fellow-worker with Mr. Douglas for many years in Arizona and Sonora. He is now resident manager for the U. V. X. company.

he increased his personal popularity thereby. Most of those that were too 'sane' to go into the 'gamble' are very sorry indeed, and I fear that some of them may smile engagingly at the next 'wild-cat' that grins at them amid the Arizonan cactus. But I am far ahead of

Jerome Verde company, under an option whereby the two properties were to be consolidated if ore was found. Under this agreement 2760 ft. of exploratory work was done on the 800, 1200, and 1400-ft. levels, without productive result. The search for ore in the U. V. X. ground

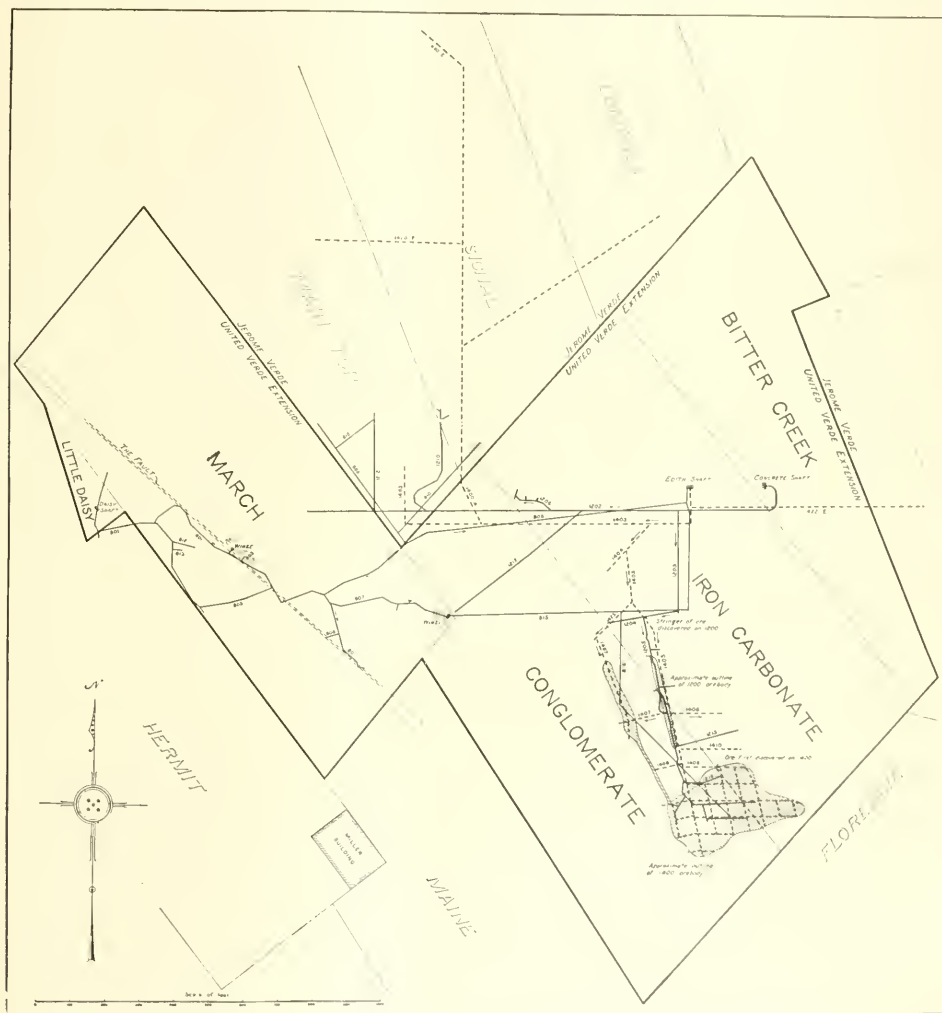

FIG. 3. PLAN OF THE U. V. X. WORKINGS. NUMBERS INDICATE THE ORDER IN WHICH THE WORK WAS DONE

my story, the most important part of which remains to be told.

In June 1913 a new shaft, called the Edith, after Miss Edith Tener, was started at a point 1900 ft. east of the first, or Little Daisy, shaft. This new shaft penetrated 180 ft. of lava, 400 ft. of limestone, 90 ft. of sandstone, and then reached the schist at 570 ft., which was equivalent to the 800-ft. level of the old shaft. A cross-cut was extended to the Main Top claims of the

likewise proved disappointing. It was decided to sink 200 ft. deeper, to the 1400-ft. level, and to cross-cut into the Main Top ground at this level, also by request of the Jerome Verde company. No ore was found. By September the \$225,000 of working capital had been spent and it became necessary to call upon the U. V. X. shareholders to subscribe for their proportion of additional stock at \$1 per share. This they did unhesitatingly. The issue, however, was previously underwritten by

Messrs. Douglas and Tener. Thus \$50,000 was raised by the sale of treasury stock. The company was capitalized at 1,500,000 shares of 50 cents, making \$7,500,000, of which now \$525,000, or 1,050,000 shares, had been issued. The old company had 500,000 shares of \$10 each, and of these 380,000 had been issued. When the re-organization was made by Messrs. Douglas and Tener they exchanged shares with the former stockholders, thus accounting for 380,000 shares. They received 170,000 shares as the profit of the promotion and of this amount they paid some of those that had helped them in the deal. They bought 50,000 shares at par, paying \$25,000; they placed 400,000 shares at par among their friends, thereby raising \$225,000 for working capital; and finally they issued 50,000 treasury shares at \$1 for further working capital. Thus 1,050,000 shares had been issued. No ore having been found in the Main Top ground of the Jerome Verde, that option was dropped in June 1915. Meanwhile all the available funds having been exhausted, including the last \$50,000 obtained from the sale of the 50,000 treasury shares, Messrs. Douglas and Tener, not wishing to ask their friends to take more treasury stock, advanced \$25,000 personally in the fall of 1914, and concurrently they engaged the services of one of the foremost geologists in the country to examine the mine and to show them where they had erred in looking for ore and to give them such advice as might haply lead them to find something before abandoning the entire project, which at that time seemed doomed. After a thorough examination, the distinguished geologist, whose name is purposely withheld, condemned the mine and strongly advised his clients to cease operations. This opinion was so strong and stated in such positive terms that the management felt relieved of a great responsibility and appeared justified in stopping work. As one of the principals says: "The position looked so bad that all further work seemed useless: it appeared time to gather up what salvage there might be, and close down the mine, swallow the loss, and forget it." However, as the Cornishman says, "Never abandon a drift until you have driven 20 ft. farther." The management persevered a little longer, and in December a cross-cut being driven toward the centre of the U. V. X. ground from the main 1200-ft. level, connecting the Daisy and Edith shafts, cut five feet of 45% copper ore. This proved to be part of an orebody 120 ft. long and reaching a few feet above the 1100-ft. level. From this orebody about \$600,000 worth of ore was mined during 1915. The prospect had become a mine, but its resources had only been touched. A drift was started on the 1400-ft. level to intersect the continuation of the ore discovered on the 1200-ft. level, but it went beyond the point where ore was expected without finding anything. No cross-cutting was done until January 1916 because a heavy flow of water had been cut south of the ore on the old 1200-ft. level, which at this time was not drained. It became necessary to install pumps at the 1400-ft. station and to provide bailers. The exploratory drift extending under the upper orebody had been stopped in a kaolinized rock,

which encouraged expectations. This point was 850 ft. south of the Edith shaft. See map, Fig. 3. As soon as the pumps were in place, a cross-cut was driven both east and west in the hope of cutting the north end of the high-grade ore uncovered on the 1200-ft. level. Both of these cross-cuts drew a blank, for, as was shown later, the orebody had taken an abrupt dip westward at a point 60 ft. below the 1200, so that the cross-cuts were too far east. The next cross-cut eastward was started 100 ft. south and found nothing, but the third (now labeled 1408) cut 16% ore when it had been advanced 40 ft. from the drift, and it continued in ore for over 200 ft. The main drift was extended into the orebody and cross-cuts were driven at intervals of 50 ft., proving a new orebody that reached to within 180 ft. of the Florencia side-line, which is the south-eastern boundary of the U. V. X. property⁵; indeed, the south-eastern end of the orebody reaches to within 30 ft. of that boundary. This, of course, was not the orebody cut on the 1200-ft. level, but a new and much bigger orebody, as the map shows. The smaller orebody discovered on the 1200-ft. level corresponds to the one known on the 1400-ft. level as the 1407, which was opened up subsequently by extending the first cross-cut run in a westerly direction.

On the 1400-ft. level the main orebody has an extreme width of 260 ft. and a length of 440 ft. It covers 62,400 sq. ft. One ton of ore occupies 7 to 7½ cu. ft. The upward termination of the main orebody is at 1240 ft. The ore is chalcocite, of secondary origin, of course. When I first saw a carload of it, just off the cage at surface, it looked like bituminous coal; it blackens the fingers. That carload assayed about 40% copper or as much as the concentrate made laboriously in the Miami and Inspiration mills. Indeed, it is a concentrate made by nature. In April 1917 the mine produced 4390 tons of 38% ore and 7029 tons of 26% ore, containing therefore 6,991,480 pounds of copper, worth \$2,167,358. The primary ore succeeds the secondary somewhere between 1500 and 1600 ft. Between 1250 and 1500 ft. there is estimated to be 2,000,000 tons of 15% ore, representing 600,000,000 pounds of copper, to be produced at a cost of 7c. per pound, leaving a profit of 10c. per pound, even if the price of copper averages no higher than 17c. during the period of exploitation. Thus a profit of \$60,000,000 is indicated. Experience in the United Verde shows that the primary ore averages 5% copper, and vertical development in that mine reaches to a depth of 1500 ft. in the schist. The U. V. X. may obtain 5000 tons of such ore per vertical foot, so that 1,500,000 tons of 5% ore, equivalent to 150,000,000 lb., is calculable. This ore, if exploited at a cost of 8c. per pound, would give another \$13,500,000 in profit. The management assumes no responsibility for any of these estimates. I give them on my own responsibility, as an essential part of the story. There should be enough rich ore to last for eight years and during this period there will be ample opportunity to ascertain the further riches of the mine. It is not

⁵The U. V. X. company owns two-thirds and Mr. Clark one-third of the Florencia claim.

likely that the output of the mine will consist only of the richer ore until all of it has been exhausted; on the contrary, reasons, economic and technical, will prompt an admixture before smelting. Therefore 3,500,000 tons of 10% ore may be taken as more nearly representing the assured resources.

Rich as it is and splendidly productive, the U. V. X. is a little mine; as measured in tonnage it makes a small output compared with the big low-grade disseminated-copper mines in other parts of Arizona. The Inspiration produces 20,000 tons per day of \$9 ore; the U. V. X. produces only 300 tons of \$150 ore, or \$45,000 per day. This is a wonderful output to be made by a small base-metal mine. During 1916 the U. V. X. produced 36,402,972 lb. of copper from 77,461 tons of ore, an average of 23.5%^c copper, besides 2570 oz. of gold and 128,468 oz. of silver, the total output being worth \$9,949,918, of which \$7,400,000 was profit. It had proved a glorious bonanza!

(To be continued)

Concrete Fords for Crossing Streams

The construction of concrete-paved fords in place of bridges across shallow intermittent streams with sandy bottoms is discussed in an article in a recent number of 'Portland Cement.' Where the bed of the stream is considerably lower than the banks, or where the normal flow of the stream is considerable, such fords are not recommended.

In constructing a ford, 2 by 6-in. timbers should be used for side-forms and drag-guides. The top of the form should be placed at the average elevation of the sandy bed of the stream. The sand between the forms is then removed to a depth of 6 in. A trench is excavated just inside the forms so as to provide a mold for a concrete baffle-wall. The trench is made deeper on the down-stream than on the up-stream side, since the former is more subject to wash. The baffle-walls are also carried across the ends of the ford. The ford should be made level at the bottom, and inclined, where necessary, at each end. The concrete is then placed. Triangular mesh or else $\frac{3}{8}$ -in. twisted bars may be used for reinforcement. When required, some sort of apron-construction can be used. If the stream is not entirely dry under ordinary conditions, a concrete box-culvert can be combined with the ford. A plain concrete ford 16 ft. wide can be built for \$2.50 to \$3 per lineal foot.

A TANK-STEAMER with no reciprocating machinery in the engine-room is being built in a shipyard on the Delaware. The propelling engine will consist of a low and a high-pressure turbine geared to a single propeller, a surface-condenser with a centrifugal pump driven by a turbine, two centrifugal hot-well pumps also driven by a turbine, and a rotary oil-pump for the turbine and gears, driven from the main gears.

^cThe output for 1917 will have averaged about 4,000,000 lb. per month.

Bureau of Mines Pyrometer

To measure satisfactorily the temperature of molten metal a pyrometer that will combine accuracy, long life, and speed of reading is essential. No pyrometer on the market is fully satisfactory for this purpose, but in the Bureau's work one was devised that has given good service for laboratory use. The illustration shows the details of the instrument. The protecting tube consists of a nickel tube tipped with molybdenum and encased in

another tube made of silfrax (graphite coated with SiC), as shown. The thermo-couple consists of a platinum element and a platinum-rhodium element carried in Marquardt porcelain insulating-tubing. The graphite and molybdenum come in contact with the molten metal, but neither is attacked by it. The nickel tube resists oxidation. The small molybdenum tip heats up quickly, the lag of the device averaging 50 seconds in metal at 1200° C., with the tip cold at the start. Other nickel tubes are threaded into the lower one to give a tube three or four feet long, and the outer end is fitted with any suitable handle.

Mining at Butte

By BEN F. EVANS

For a short time prior to June 1917 the labor element in the Butte district passed through a period of unrest. This was caused by many unusual factors, namely, the general prosperity of the working people throughout the country, caused by high wages, the war crisis, numerous strikes, the pro-German propaganda, professional agitation of the I. W. W. type, and undesirable working conditions. All of these factors tended to bring the majority of the miners to a common understanding. The unrest was brought to a climax by the fire in the Granite Mountain shaft, on June 9, when 160 men lost their lives. Two days later the Butte Metal Mine Workers Union was organized. This was inevitable and would have happened in a short time even if there had been no accident, but the opportunity, when all the miners had so much in common to talk and think about, was seized by the labor-leaders. Demands were then drawn up and presented to the operators. They included an increase of wages, changes in working conditions, abolition of the rustling card, committees composed of company representatives and union men not only to settle disputes but also to examine and make reports on underground conditions. These demands were not accepted. A strike followed. It can be added that many of the demands in a modified form were agreeable to the operators, but as modified they did not suit the union.

During the period between June 11 and September 24 the production of copper in the district was practically nil. Most of the miners had only enough men to keep up repairs and operate pumps. Miners left Butte by hundreds, as there was plenty of work in neighboring mining and construction camps, while many men went to the harvest and hayfields. Those with families, forced by circumstances to remain, received financial aid from the miner's organization, it is understood. Several local societies and business concerns contributed financially to the aid of the union. It is known that the organization also received help from organized labor outside the Butte district. During the early part of this period the crafts also were in an unstable condition. Some were, and others were not, in favor of affiliating the new union with this organization, and a strike was daily expected, but when it came to a vote the majority of the different crafts decided against affiliation. This decision was disliked by the members of the new union; they maintained it was unfair, and based their claim upon the fact that an organization with a small number of men had the same power as one with a great many; thus the decision was not representative of the men's feelings or sympathies.

It must be understood that the miners' strike in Butte

automatically closed the concentrators and smelters in the cities of Anaconda and Great Falls, as these plants depend upon the Butte mines for their ore. The members of the smeltermen's union were then easy victims for the strike germ, which pervaded the atmosphere at that time.

About this time, or, to be exact, on the thirtieth day of July 1917, an agreement was entered into between the Anaconda Copper Mining Co. and the State Metal Trades Council, affiliated with the American Federation of Labor, through its local unions, which apparently satisfied all concerned, and went a long way in straightening out the labor situation. It conceded a rise of 25 cents per day (beginning at \$3 to \$5 as the standard wages for different occupations) for each two cents rise of copper above 15c. per pound, as set out in a detailed schedule annexed to the contract. All over-time (including Sunday work) to be paid for at the rate of time and a half. A weekly pay-day is established. The company agrees to employ none except members of the affiliated unions. The State Metal Trades Council agrees to expel or discipline any rebellious 'locals' breaking the contract. The company absolves itself from settling any question of jurisdiction between local unions, leaving that to the Trades Council and American Federation of Labor.

From the time the agreement went into effect no trouble of any consequence has arisen from the crafts, although there was a walk-out (but no strike) among some of the electrical workers. This was of short duration. The fact that the Government set the price of copper at 23½ cents per pound at this time would have naturally meant a reduction of wages, due to the sliding scale in use, based on the price of copper. The companies, however, decided that it would be better to maintain the existing rate of wages, which was based on copper at 27c. per pound. This scale is to be in effect until the first of January 1918, at least.

During the strike period, one noticeable condition was observed, namely, the absence of serious violence, such as ordinarily accompanies these strikes. The union men had an understanding that violence or lawlessness was not desired, and would not be tolerated. The one black mark in the entire trouble was the hanging of Frank Little, a well-known I. W. W. leader and organizer. The presence of Federal troops in Butte during the height of the trouble and at the present time no doubt had a great influence upon all law-breaking people. The fact that wages were based on 27c. copper, that a great many men were tired of loafing and out of funds, and that no end was in sight for a final settlement, started the men back to work. The dearth of miners in the district at this time was noticeable.

ELM ORLU MINE, OWNED BY W. A. CLARK

PARK STREET, BUTTE, LOOKING WEST

The smaller operators, particularly the zinc-producers, the Butte & Superior Mining Co. and the Clark interests, were the first to approach anything near normal ore production. The Anaconda Copper Mining Co., not being able to start all of its properties at once, and having to get its smelters into working order, was just a trifle slower in getting into its stride again, but soon took the lead in number of employees. As soon as it was generally known around the country that the Butte mines were again working, the men gradually began to come back. All of this in spite of the fact that placards were circulated in many places advising the workers not to return to Butte, because the strike was still on. That the men wished to return was no more than to be expected, as a great many who went away did so just to avoid trouble, and not because they had any particular grievance against the operators. It is also recognized among the miners that Butte affords the best living conditions of any camp in the country. There are no bunk-houses or mess-houses at the mines. The men find accommodations wherever they choose, and most of them have well-heated rooms, with hot and cold water, in some of the most modern blocks in the city, where they are close to any recreation they may desire.

The Anaconda company has been starting up its largest mines as fast as the return of men warrants, until at this time, January 1, 1918, the company is employing 94% of the normal force, and working most of the mines to capacity. This seems remarkable in view of the fact that so many men have left the city to join the colors. In the month of November the output of copper was 21,666,332 pounds, while the output of zinc was 3,955,707 lb. These figures afford ample evidence that operations are rapidly approaching normal.

The high price of silver has helped generally. Old silver properties that had been lying dormant for the past 25 and 30 years suddenly sprang into activity. Practically all of the present large producers in the district showed interest in local silver properties. The demand for manganese for the steel industry went hand in hand with the silver development, most of the old silver mines having good surface showings of manganese. The Anaconda company is developing the Nettie, Orphan Girl, and Bonanza claims. The Butte & Superior Co. is working a group of claims in the silver district, the most important of which are the Germania, Tzarina, and Humboldt. The Clark interests are working the Moulton, Anselmo, and Travona properties. The Butte-Detroit Copper & Zinc Co. has been mining manganese ore at the Britannia and concentrating it at the re-modeled Ophir mill, situated in the south-western part of the city. The Davis-Daly Co. has been doing extensive development work at the Hibernia and Mount Moriah claims, both old silver-producers. This work means a great deal for Butte's future as it enlarges the mining area about one-third and extends almost four miles south-west of its present productive area. These operations have caused much property to change hands, a good omen in the mining world.

The North-Butte Mining Co. has been under great handicap as far as production was concerned. Much repair work had to be done at the Granite Mountain and Speculator shafts. At present the Granite Mountain shaft is being concreted. This is the first work of that kind yet attempted in the district, and the result will be awaited with keen interest. The walls will be solid concrete and heavily reinforced with steel rods. A great many arguments have been advanced in connection with this work. The contention among some mining men is that this work will be more expensive and will not have any greater fire-resisting qualities than a cheaper construction. The heavy moving ground so common in the Butte district is liable to cause considerable trouble and make repairs run high. Ore is being hoisted from the Speculator shafts and shortly after the first of the year a normal production is expected. The company is carrying on development work in the eastern part of the district, a new territory that has not been extensively developed.

In conclusion, I would summarize recent changes as follows:

On December 18 the Metal Mine Workers Union voted to call the strikes off, and return to work. Wages for miners before the trouble were \$4.75 per diem, and at present are \$5.25. Payment is based on the sliding scale with a base of \$3.50 per day when copper is under 15c. and advancing 25c. for every 2c. increase in the price of copper. The rustling-card has been modified. A weekly pay-day is now in operation and has been received with much gratification by the miners. The Anaconda pays in cash, whereas the other companies pay by check as formerly. The weekly pay-day eliminates the wage-scalper or assignment-shark. Formerly all employees were paid monthly.

A great deal of work has been done for the safety of miners, and on precautionary measures in case of fire. This is shown clearly by extensive work that has been done in concreting the Tramway shaft, by the Anaconda company. This concrete is comparable to cement plaster on metal lath. The metal lath is stretched over the shaft-timbers and walls, then nailed in place. The cement is then applied with a cement-gun. This is said to be fire-resisting, and when proved so, it no doubt will be generally adopted at all mines in the district. The same system is being used in underground stations and on fire doors.

Ninety-four per cent of the normal working force is at work, a great deal of development work is going on in a long-forgotten portion of this mining district, and a general feeling of prosperity prevails, as is clearly shown by the increase of business, the successful flotation of the Liberty Loans, Y. M. C. A., and Red Cross campaigns. When these were carefully examined it was found that the numerous small contributions from the mining men, not including the operators, when taken collectively, went a great way in making up the grand total, amounting to a local over-subscription of each allotment.

Mining Laws for Russia

By HORACE V. WINCHELL

[Mr. Winchell was asked by the Ministry of Commerce and Industry at Petrograd to submit suggestions for framing mining laws, in Russia, based upon his experience in the United States. He complied with the request and we are enabled to publish herewith a part of his recommendations, believing them to be interesting to mining engineers in Russia and America.]

We are accustomed to dividing mining laws and regulations into two parts: first, mining laws proper that concern the relations between the prospector and mine-operator and the Government or private landlord, which define the status of the prospector, establish method of procedure, protect him in his possession while searching for mines, and give him assurance of title when all the required conditions have been fulfilled and valuable minerals discovered; second, mining regulations concerning the operation of mines and the safety and health of the employees. It is my purpose to discuss here only mining laws as defined under the first class.

Experience has shown that the prosperity of the mining industry and consequently in large measure, the prosperity of a country, depends largely upon the character of its mining laws. If they are favorable there will be great activity in the operation of mines and great collateral development, such as the building of industrial communities, the construction of railroads and large manufacturing establishments. If the laws are not such as meet with the general approval of the prospector and the capitalist the mining industry languishes and the industries of the country, which is thus compelled to rely upon imports from other lands, also fail to reach their highest development. As an illustration of this fact permit me to call attention to Chile in South America, which lies upon the west slope of the Andes mountains, and which, although not exceptionally rich in minerals, still, because of a liberal progressive mining code, has a mineral production valued at more than 140 million dollars per annum. Contrasting this with Argentina, which is a country of more than double the population of Chile, and which lies upon the eastern slope of the same mountains, and has equally great mineral resources, and yet, because of a difficult code of mining laws has a mineral production of less than \$300,000. As a further illustration of the great importance of the mining industry permit me to state that the western half of the United States was developed first for its mines: railroads were constructed, steamship lines established, and the large and important industrial communities of the West grew up around these mining centres and as a direct result of their activity. It is a significant fact that 60% of the business of all the railroads of the United States

is derived from the products of the mines and quarries. These facts and the further fact that metals are greatly needed not only in times of peace, but in time of war for maintaining and defending a country's territory, are ample justification for a serious consideration of the question.

Mining laws, in order to be operative and just, should be brief, simple, clear, and uniform. They should be brief and simple because they are to be read and interpreted by individuals who have little knowledge of legal phraseology. In this connection permit me to point out that the Federal mining law of the United States, a copy of which I happen to have with me and enclose with this letter for your consideration, comprises only 28 articles and requires for its presentation but 9 printed pages. There has been considerable supplementary legislation and the Land Department has promulgated a considerable volume of regulations for the carrying out of the terms of the law, but the law itself is ideal in its brevity and simplicity. The law should be uniform so far as possible in order that the prospector may understand clearly the requirements and may not unwittingly make mistakes and fail to comply with the provisions of the statutes. Thus, if there is a different law for the location of copper and gold and iron, and other metals, confusion will inevitably arise.

The ideal mining law is one that protects the Government and the public interest on the one hand and at the same time protects the miner, and is so liberal in its provisions as to induce him to take the chances inevitable in the mining business and expend his time and money in search for and development of new properties.

The Government should be protected, first, by requiring a reasonable amount of development in each year. No individual or corporation should be permitted to hold indefinitely large tracts of land for mining purposes without making serious effort to develop the same, and to work the mines on a reasonable scale. The Government should likewise require as nearly constant operation as is consistent with economic conditions. On the other hand, the Government should not attempt to prescribe rigorously how much ore should be produced every year nor at what price the product should be sold. It is manifestly impossible to thus control economic laws. The owner of a good mine will work his mine to its maximum capacity whenever he can dispose of its product, but when marketing conditions are difficult and the price of metals is low so that the mine cannot be operated at a profit, he should not be required by law to continue to do so.

In the third place, the Government expects and should receive some revenue from its mines in the form of taxes

or royalty. By this I do not mean to imply that the Government should attempt to make large profits out of the operations of individuals or corporations. This has been a temptation in times past and has not worked out to the advantage of the community. A reasonable tax upon the product based either upon the valuation of the property or upon the net profit of the operation is always fair and cannot be objected to. But there are so many uncertainties connected with the mining industry that unless a large reward is possible the prospector and the miner will not exercise their activities. Furthermore, the benefits to the community and to the Government that arise from the development of mines in an indirect fashion is so much greater than that which could be derived by a heavy tax upon the mines themselves that it has now been generally accepted as true that a liberal policy produces the best results.

The miner must be protected in exclusive and undisturbed possession of his property. Many countries require an actual discovery of mineral in place before granting to the prospector any form of possessory titles. This practice is based upon ancient laws and customs. The more modern codes of mining law permit the prospector to stake his claim wherever he desires to prospect and protects him in his possession for a reasonable term of years so long as he continues in good faith to search for ore within his claim. The mining law of the United States requires a discovery before location, but this provision of the law will probably be changed in the near future.

The miner should have freedom of operation. He should not be unduly hampered by governmental restrictions and regulations. It has been my experience that the mining engineers employed by governments and given authority over the operation of mines owned by individuals and corporations are not nearly so well qualified to direct such operations as the men employed for the purpose by the mine-owners. There is in the United States no such supervision of mining operations by Government officials or engineers. The only control exercised is in connection with regulations for safety and health. It is my understanding that in Russia mines owned by foreign companies are compelled by law to employ Russian engineers as managers. I know of no other country where such a law prevails. It is apparent from brief consideration that such requirements are not only distasteful to the owners, but actually a handicap upon the Russian mining industry, since mining companies of large capital and resources, with well-organized technical staffs, are not likely to view with favor the installation at their mines of men whose qualifications are unknown to them.

The mine-operator should not be restricted in the marketing of his product. He should be permitted to seek the best market and make the best possible terms either at home or abroad. Referring once more to the United States I may be permitted to point to the fact that there is no limitation whatever upon the exportation of its mineral products, either raw or manufactured. Contrast this situation and the consequent magnitude of

American business in iron and steel products with that of Brazil, where there exist the largest deposits of high-grade iron ore known in the world, and yet a condition of industrial depression certainly attributable to at least a limited extent to the refusal of the Brazilian government to permit the export of iron ore and other crude minerals. Look again at Sweden, where there exists one of the largest deposits of iron ore known today. This mine, at Kirunavara, contains enough iron ore to supply Sweden for more than 600 years, and yet the Government restricts its operation and production and thereby prevents extensive and large development.

The fundamental idea that I have in presenting these few considerations is that no pound of coal, or iron, zinc, copper, or lead is of value until it is used. It does no one any good to keep it in the ground. It is useless to fear for the prosperity of generations yet unborn. They will look out for themselves. The art of metallurgy and the use of metals are so constantly changing that no one can foresee what will be required centuries hence. Consequently the nation which makes the freest use of its mineral wealth, throwing it open most liberally to the initiative of the world's miners, is the nation which in the immediate future will benefit most largely through the possession of these mineral deposits. American capital, like the surplus capital from other countries, will go where it finds the best opportunity for employment and is promised the best return. Russian mines will be developed rapidly and extensively if the Russian laws are as favorable as those of other countries.

THE mineral output of Alaska in 1916 is valued at \$48,632,138, being an increase of nearly 50% over the output of the previous year, which was \$32,854,229. This increase has been due mainly to the activity in copper mining. The output of that metal for the year was 119,602,028 lb., against 86,509,312 lb. in 1915. During the year 18 copper mines were in operation, nine in the Ketchikan district, six in the Prince William Sound district, and three in the Chitina district. The average copper content of the ore mined was 9.7% and the value of the combined gold and silver content was \$1.60 per ton. Twenty-nine gold-lode mines were operated during the year, and the production was valued at \$5,912,736. The average value of the combined gold and silver content for all silicious ores mined in 1916 was \$1.70. The value of the placer-gold production in 1916 was \$11,140,000, an increase of \$660,000 over 1915. This increase came from the newly developed Marshall and Folorana districts. During the year 139 tons of metallic tin, valued at \$121,000 was produced, chiefly from the York district, in the Seward Peninsula, where four dredges were operated, two of which worked on gravels carrying gold as well as tin. Much stream tin was recovered from the placer deposits in the Hot Springs district. About 1500 tons of antimony ore, and about 47 tons of scheelite concentrate, including a little wolframite, was produced, mostly from the Fairbanks district.—Bull. 662 A, U. S. Geological Survey.

The Business of War

By CHARLES T. HUTCHINSON

Commercial United States doesn't know 'where it is at,' and no wonder! Proprietors of big business enterprises, presidents, managers, and what not, find themselves no longer in authority. They are order-takers, not order-givers. Our Uncle Samuel is the one and only order-giver. Take thirty billion dollars, an inconceivable sum of money, chuck it into the manufacture of all sorts of material utterly foreign to peace times, and it is not surprising that most people find themselves at a temporary loss to see anything farther ahead than the exigencies of the moment.

Nevertheless, it will not take long for business to accustom itself to the new channels, although it may be rough going for a few months longer. As military needs become more clearly defined and standardized, and as requirements whether of men, ships, ordnance, or supplies become resolved into definite quantities within definite time, business men will be able to see what proportion of their product they may devote to maintaining their hold on former customers. As it is, the digestive apparatus of commerce is trying to assimilate an altogether new diet. A certain amount of economic dyspepsia, under these conditions, is not surprising. This condition is most pronounced in the great manufacturing districts. New York is the focal point, the nerve-centre of the War's industrial activities, while Washington, only a few hours away, issues its mandates to the captains of industry. From one end of the country to the other everybody's doing it, and doing it with a will too. There are no half-way measures about the American manufacturer. "Any part, or all of my output is at your disposal." That is the way they talk, and that is the way they act.

Some twenty years ago, we had a slight unpleasantness with Spain. In those days the country's need was regarded as the business man's opportunity. The vendor of obsolete transports, embalmed beef, shoddy uniforms, and adulterated medical supplies clustered around headquarters like flies. An altogether different man is clustering today. His job is to give rather than to take. Those who have private means are working for nothing; those who haven't are giving their services for a fraction of their earnings in civil life, while big and small industrial enterprises are, in large part, giving up their normal lines to devote their productive capacity to Government needs. Of course, there is some profiteering. This is not the millennium. Such profiteering as there is, is relatively small and unimportant. There are parasites who, possessed of some capital, are hoarding food-stuffs, especially such necessities as sugar, and are plying their nefarious trade through back alleys and behind

closed doors, selling in small quantities at famine prices to those whom necessity makes an easy prey. If that class of profiteer could only be reported to the nearest office of the Food Administration their activities would soon be stopped. Another kind of profiteer is going into the market, buying anything from scrap-iron to tin-plate, wherever he can find it, and taking his chances of being caught and his stock commandeered by the Government. This might be regarded as legitimate speculation, and so it is except during times such as these, when such materials are so urgently needed by the Government for a more urgent purpose.

Then there is the inn-keeper, whose activities are most pronounced in New York City. He deserves a paragraph to himself. His menus are decorated with the slogans of the Food Administration. The victim, whose business compels him to visit the metropolis, reflects upon the all-pervading spirit of patriotism, until he sees the prices. That is the first shock. The second comes when he views the size of the portions. Apparently patriotism has enabled the Boniface at one time to increase his prices about 25% and decrease the size of portions another 25%. Glorious economy! Splendid patriotism! It has been said that the saving in foodstuffs has aggregated some thousands of tons monthly, and elicited the commendation of the Food Administrator himself. Here we have economy de luxe, while the ultimate consumer, scorned as usual, folds his tent and silently steals away, all the while trying to devise ways and means of camouflaging his expense account.

The most stupid profiteer of the lot is the man who, placed on his honor in the execution of a war contract without fixed price, renders a bill carrying an exorbitant profit, with the thought that he won't be caught at it. Here is a case in point. The execution of a certain order for war material was placed with a manufacturer. In due course the work was finished. Then came the bill. It amounted to \$37,000. The engineer who was acting as purchasing agent made an estimate of cost at \$16,500. He called in an independent engineer, who estimated \$16,700 as the probable cost. A Government department made an estimate based on the cost of duplicating the work elsewhere. Their figure was something under \$17,000. All the documents and exhibits in the case were forwarded to the powers that be. Something is likely to happen to that contractor.

Uncle Sam is an indulgent taskmaster, and will go to extraordinary lengths to help those who are 'on the level,' but woe betide those who are not. Manufacturers who have turned their entire plants over to the Government are practically working on a cost-plus arrange-

ment, generally 10%. They can't lose money on this basis. All they are asked to do it to devote their best efforts to the production of perfect work and material in record time. Others who are taking work at fixed prices, find that the Government will aid them in obtaining materials at costs that would be impossible for the execution of private contracts. Then, again, contracts are made based on the costs of labor and material at the time the contracts are executed, and subject to adjustment for any fluctuations that may take place between commencement and completion. What could be more fair?

The Government has at its disposal any quantity of expert engineers, estimators, cost-accountants, and other specialists who are devoting their time to see that work is well done, and that the expense is in keeping with present conditions of labor and material. The Government will not knowingly pay for defective work any more than a private individual.

There are two divisions of work in this country today: that which is directly contributory to the conduct of the War, and that which is not. The two basic industries, agriculture and mining, are in demand as never before. Lessons taught us by the experience of our Allies have been taken to heart. Governmental supervision of both these great essentials is already an accomplished fact, and while the administration of both is still in process of development in many details, yet the foundation is there and the rest will follow, it is to be hoped, with as few blunders as possible.

Industries not directly or indirectly pertaining to war-needs will suffer, and in some cases, cease altogether until Victory perches on our banner. Work will be available for all willing men and women, perhaps at something other than that to which they have been accustomed, but work nevertheless, and at record high wages. The labor problem is not to find work, but to make those work who don't want to work.

Governmental assumption of power to fix prices must be extended to the fixation of those elements that make costs. The one element of uncertainty is labor; in fact, in the labor situation lies at once our greatest strength and greatest weakness. Enemy propaganda is doing its utmost to attack us at this point, and it is to the credit of far-sighted labor-leaders like Samuel Gompers that thus far our productive capacity has not been materially impaired. If the elements entering into the cost of living can be held within reasonable bounds, so, in turn, can the question of wages be settled. As it is, wages in some trades would be attractive to bank presidents, while the clerks, book-keepers, salesmen, and other members of the unorganized 'submerged tenth,' between the upper and nether millstones of low pay and the H. C. L., are being ground to dust.

What is more serious than wages is the tendency on the part of the workmen to limit output. This evil has been growing for years, and, according to some investigators, is worse now than ever before. To discover the cause involves an investigation of industrial conditions

for many years back. In a few words, it is the effort of labor to fight one evil with another. Not so many years ago, capital operated on the principle of get all you can in exchange for as little as possible. Labor has adopted at least in part this same principle. It is defenseless. Capital was the first to see the light. Whether this improved vision is due to higher morality, or whether it was forced by the growing strength of the labor-unions is of little consequence. It is sufficient to consider conditions as they are today, and that is that the capitalistic boss has been succeeded by the labor boss. Neither is for the best interest of the Nation. Both represent the quintessence of selfishness—a selfishness that, in view of the country's present need, is treason.

Some of the more advanced thinkers among labor-leaders, notably Samuel Gompers, are trying to stem the tide that they themselves started. Certain it is that conditions will not improve without the active co-operation of labor-leaders, great and small, who will join with employers in doing their utmost to point the way of duty and patriotism. There is even a greater need for the co-ordination of the forces of labor than of the Administration at Washington. Every man who calls himself an American should be made to realize his responsibilities in this great struggle of struggles. Every one of us is an integral part of the fighting force of the United States, whether he be clothed in olive drab, navy blue, or the unsightly but practical overalls of the workman or farm-hand. There is no five o'clock whistle on the Hindenburg line. There are no Saturday half-holidays at Essen. We have to defeat a nation in arms, and only by a greater nation in arms can it be defeated.

Before long the war-after-the-war will receive attention. It is receiving attention now from the more far-sighted business men, who can see farther ahead than the ends of their dignified noses. In the conduct of a successful business enterprise, brains and money are spent lavishly in the creation of that intangible something known as 'goodwill.' Many have tried to describe it, many have tried to capitalize it, and many have made a hash of it, nevertheless there is no such thing as business success without it. It is, in effect, the feeling of confidence and security that forms the invisible connection between those who serve and those who are served; that depends, for its maintenance, upon continuous upkeep in good working order. It is the continuous upkeep of it that, in these days, is the sticking point. "How am I going to serve my old customers when the Government is taking 85% of my output?" said a distracted manufacturer a few days ago. This question may be answered by reciting the policy, if it may be so called, of a prominent manufacturer of certain specialized apparatus, whose output for the next two years is all sold for war purposes. Inquiries for the purchase of his apparatus continue to come in at an even greater rate than before the War. Every inquiry is answered promptly, stating, on the all-important question of delivery, that the condition of the market will be carefully examined and a reply sent as soon as possible. Then he carefully

canvasses all possible sources of supply, including every factory for apparatus similar to his own, all second-hand apparatus that may be in serviceable condition, and other apparatus that, in a pinch, might be used as a substitute. This information at hand, he is able to serve his customer, with apparatus other than that of his own manufacture, perhaps, but nevertheless the customer gets what he wants, and during these times will remember the man who did not desert him in his hour of need. Where nothing can be done, the manufacturer's willingness to help counts for a great deal, and will not be forgotten when the War is over, and everybody will be scrapping for orders in the good, old, time-honored way.

The British manufacturer has learned his lesson, and is looking far ahead with an eye to what will come afterward. The pictorial British weeklies carry practically as much advertising as they did before the War. It is many months since English manufacturers of automobiles have been able to execute an order for any private party. Nevertheless they are giving as much space as before to setting forth the merits of their product, its improvements, its record in the war-zone, and soliciting orders to be filled when the War is over. The same is true of class and trade publications. Our London contemporary is carrying as much, if not more, advertising space than before August 1914.

There is nothing so dead as that which is forgotten. American manufacturers will do well to ponder over this statement and remember its truth. There is no excuse for lack of attention to evil inquiries, even if nothing can be done with them at present. The commercial fabric of the Nation must be preserved, and the holes patched up, for the trade and industrial war that is to follow the present physical struggle will be waged none the less bitterly and relentlessly from the fact that blood-letting will have ceased.

Many manufacturers think they are worse off than they really are. A few inquiries or orders that for the present cannot be filled stampede the herd. If the salesmen would put in their time trying to obtain what is wanted from any available source, they would earn their pay through the maintenance of their employer's goodwill, and lay up for themselves treasures untold when the day of reckoning comes, as it surely will. After it is over, this war will bring about a separation of the industrial sheep and goats. Those who regarded their temporary prosperity during war-times as a permanent institution will collapse like pricked balloons when Governmental orders have ceased, unless they maintain their connection as best they can with those whose business they formerly solicited so eagerly. "We are so well-known that they will surely come back to us" is a dangerous viewpoint. Customers are fickle jades, as a rule, and the continual receipt of the weekly bunch of violets is more effective than the occasional splurge of a box at the opera. Nothing is so irritating as unanswered mail, especially when the man whose letters are unanswered is sitting on a red-hot stove waiting, hoping against hope,

that a needed replacement will arrive and enable him to go on with his work.

Metal mining is a war-necessity, and the machinery required should rank high in the rulings recently established by the Priority Board. Mining-machinery manufacturers and dealers in supplies for mines are doing their best to meet the requirements of their customers, while, at the same, building everything from ships to munitions for war purposes. Many factories are running at 100% load-factor for the first time in their history, while some are operating at as high as 200% overload. Here is a chance for the real efficiency engineer. The cry is always for tonnage, and yet more tonnage. In civil life the element of cost is paramount. In military life, it is the element of time. Cost is secondary. To hasten the end of the War a month, a week, a day, or even an hour, is to save untold wealth in human lives and energy.

One is proud of the way American business is putting its shoulder to the wheel. We know nothing definite as to the progress that has been made. There are military reasons why we should not. Nevertheless notes of cheer are heard above the din of battle. It seems that several submarines have gone to their final resting-place. Several ships flying the American flag are on the high seas, a novelty in maritime circles. Several American soldiers are now in France, and more are to go. Congress is in session, and may do something to the second-class postal-rate increase that will give the publisher a fighting chance. We have wheatless days, meatless days, and some of us are having sleepless nights. Nevertheless we are proud of our nation, the cause it has espoused, and are firm in the conviction that American brain, brawn, and dollars will supply the impetus that will give the finishing blow to Attila and his Huns.

JAPANESE steel production is increasing rapidly. Through recent investigations by the Mining Bureau it is learned that the total producing capacity of Japanese steel mills was 888,000 tons, in round figures, at the end of August. During the first half of the present year 289,000 tons of various shapes were produced exclusive of the colonies. Of this amount 200,000 tons came from the Government Steel Works. The Japan Steel Tube Co. turned out 22,000 tons; the Japan Steel Works, 14,000 tons; the Kawasaki Dockyard Co., 12,000 tons; and the Kamaishi Steel Works, 10,000 tons. By the end of this year the products of those mills will reach at least 570,000 tons net. Compared with the preceding year this is an increase of 50%. If this rate of increase is maintained, next year will see a further increase at least to 850,000 tons net.

PLATINUM has been found in basic rocks in many parts of the world. Chromite is also common in similar rocks, and consequently it is sometimes accompanied by small amounts of platinum, in one case, reported from South Africa, the amount being 1 dwt. per ton.

Joplin and the Komspelter Region

By OTTO RUHL

The past three months has represented a period of re-adjustment in the zinc and lead districts of Missouri, Kansas, and Oklahoma; it has been one of the most severe from the point of view of strained credit, wholesale closing down of mines, and even abandonment of some localities ever experienced, with perhaps the single exception of 1907. This is partly brought about by low prices and partly by gradually rising costs of production. The only relief in sight has been the transfer of operations from the low-grade properties to the high-grade, a relief often obtained at great sacrifice and disorganization of working-forces. The transition from a prosperous industry in 1916 to a fight for existence in 1917 has been marked by many struggles. Nevertheless the momentum of the highly prosperous times of 1916 and the earlier part of 1917 has been such as to carry the annual production for lead and zinc to new high levels, and records have been made that can hardly be expected to be attained again for some time. Eleven months of 1917 shows an increase of 100,000 tons of zinc concentrate over 1916. The increase in lead concentrate is 11,835 tons. The increase in zinc was over 34% and the increase in lead 25%. The net increase in value for the two products is \$5,000,000 on shipments alone, and to this must be added the surplus in the bins, totaling 33,000 of zinc concentrate and 8500 tons of lead concentrate. All of this increase was made in the face of a decrease in the average price of zinc concentrate. This decrease amounted to \$9.18 for blende concentrate and \$27.30 per ton on calamine concentrate. The increase in zinc prices therefore has come from the gain in tonnage, and not in price. The increased value of \$19.11 for lead concentrate comes from both an increase in price and an increase in tonnage.

The falling price for zinc concentrate and the rising prices of supplies and labor have steadily ground down the operators in sheet-ground until every item of profit has been extinguished and the balance, in many cases, is on the wrong side of the ledger. Only in a few instances, where units of operation were large and where the percentage of extraction was high, have they been able to hold out. Out of 150 mills in the sheet-ground district, around Webb City and Cartersville, one can count on the fingers of two hands those that have survived. Even these may succumb; the end of the year may see further additions to the plants closed-down or removed to other localities. This will wipe out a district that supplied 50% of the entire production of the region, a production that ranks as high-grade and that apparently cannot be replaced elsewhere in the United States.

The impossibility of replacing this output is recognized by all. The concentrates are free of any lead or contain extremely low percentages of lead, making them highly desirable by smelters engaged in the manufacture of sheet-zinc or for some classes of 'brass special' spelter. A large proportion of these concentrates would assay 60 to 63% zinc, 0.005% lead, and 1% iron. Only mines in parts of Joplin and Alba Neck City would show the same degree of purity elsewhere in the district. On the other hand, throughout the year there has been a steady growth in a mill-product that runs 58 to 60% blende, 1 to 1½% lead, and 2% or better in iron. It is evident from the trend of production that no such tonnage of high-grade ore can be expected from any part of the region now showing increased development. If anything, the grade is likely to be lower than higher.

The only locality where high-grade ore is being developed is at Waco, north of the old Lawton mines. Here a number of new mills are yielding high-grade concentrates. The ore itself is not only rich but of good quality, and while the developments have not yet reached such a stage as to ensure a large production the mines already developed, together with the drilling now in progress, offer considerable promise for the future. The whole trend of development has been going toward the Oklahoma portion of the region, and the work already done may be rapidly extended north-east of Picher as far as Crestline, Kansas. One of the recent developments has been the testing of the Newton farm, east of Crestline, the results of which were so promising as to induce the American Metal Co. to pay \$78,000 for the tract. The development by the Union Metals Co. at Waco seems to be extending the productive area south-westward and north-westward so that a possibility of a continuous line of operations is now within the realm of possibilities from Picher, Oklahoma, to Ashury, Missouri. A large number of drills are now being placed on the Missouri side near Ashury with the idea of testing that portion of the prospective mining area. The year therefore has seen a tremendous development of new territory covering portions of the States of Oklahoma and Kansas with the promise of this same extension of development into Missouri at the northern end of the line.

Coincident with this prospecting and development work has been an era of mine investment that has not been altogether sane. The richness of some of the mines has induced the pyramiding of royalties. On top of the high royalties have come the gradual paying of higher prices for leases until there have been sales well above the million-dollar mark in single units, and some sales

have been reported as high as \$2,000,000 where combinations of properties were made. It is doubtful whether many of the high valuations can be justified. Gradually there is growing a better sense of values, but this better sense has come rather from the shock of a falling ore-market and the realization that exploitation in the new district curtailed the highest cost of production in the entire region, and that conditions were growing worse instead of better owing to the increasing cost of material and the growing inefficiency of labor. The latter is an extremely serious factor. It has been brought about by the unusually large number of new mines that have come into operation so quickly as to require large numbers of laborers. The constant bidding of one concern for men has tended to raise the price of labor and to lower its efficiency. This condition has extended even into the older settlements until it is no uncommon thing to hear a mine-worker say at Webb City: "They will pay me \$5 a day just to stay underground in the Oklahoma district, so why work up here." Conditions have gotten far beyond the control of the mine-operators in this respect, and while there is undoubtedly valid reason for paying higher wages at Picher, there is none for the failure to receive an increase in actual labor performed. If the operations showed the same efficiency in the Picher area as they do in the sheet-ground area of Webb City, the cost of production would not only be much lower than it is, but the production also would be greatly increased.

The opening of the winter season totally disorganized both railroad and highway traffic throughout the new mining area extending from Commerce, Oklahoma, to Baxter Springs, Kansas. In the very midst of repairing the rock highway between Joplin and Commerce came 18 inches of snow accompanied by cold weather. This, followed by thawing with heavy truck traffic over it, has been very disastrous and the highway is in an extremely bad condition. Very heavy traffic will be considerably delayed until such period of time has elapsed over a dry season to make possible the repairing of the damage already done. So far as dirt roads running off the rock highways are concerned, they have been impassable for the past ten days. This precludes any possibility of hauling coal to the mines or hauling ore away from them. These conditions have also seriously interfered with labor getting to and from the mining properties and their homes. Production here therefore suffered greatly for the past ten days and there is little hope of improvement for another fortnight at least. Both of the railroads into Oklahoma district are new. Their roadbeds have not been settled and the heavy snows have demoralized traffic over the railway until the efficiency is very low and little improvement can be expected here during this winter. In view of the prevailing conditions there can be little increase in output during the coming three months from the new district and it is doubtful if it will hold its own during that period if road conditions are not improved and a better supply of cars

becomes available for coal-supply and the transport of ores. Already the mill-bins are full and it would be surprising if shipping conditions are improved sufficiently in the next quarter to take care of this surplus. Unless this surplus is sold operations can hardly be financed, except by one or two strong concerns. This will act as a brake upon production during winter. An estimated output of 5000 tons per week from the new district during the next three months is believed to be conservative. The coming of the spring, however, will see a notable increase, if the market is favorable and fuel is available.

A Substitute for Corrugated Iron

The British, in their efforts to practice economy in the use of steel and iron, have developed and are now manufacturing a satisfactory substitute for corrugated iron and sheets. It is an asbestos-cement roofing material. During the last year a large plant has been built in England for manufacturing this product. The method of making it is as follows: After being finely ground and freed from extraneous matter the asbestos, which acts as the reinforcing agent, is mixed with portland cement in the proportion of about 1 to 6, and made into a paste with water. This paste is then taken to a machine of the paper-making type, where, on a large revolving drum, it is formed into sheets or felts. After the sheets have been trimmed to size, they have the corrugations impressed on them. The important condition for this operation is to insure that the tops of the corrugations are as strong as the other parts of the sheets. Finally the sheets are subjected to a 'seasoning' process. The corrugations are made to the 3-in. pitch which is usual with corrugated-iron sheeting, not to the 2½-in. foreign pitch, and they can therefore readily be used to repair roofs of corrugated iron. One of the chief advantages claimed is their durability and resistance to climatic conditions, especially to an acid-laden atmosphere, which rapidly destroys corrugated iron. The sheets are also fire-proof and are poor conductors of heat.

Brazilian manganese shipments, which, owing to the closing of other sources of supply, are now being made in large quantities to the United States, amounted to 245,088 tons having a declared value of \$5,733,000 during the first six months of 1917. The chances are that these will largely increase if the Brazilian railroads which carry the cargoes from the interior to tidewater and the conditions of South American shipping are able to cope with the increasing demand.

The British Minister of Munitions has forbidden, except under permit, all dealings or proposals for sale of tungsten or molybdenite ores, and will fix maximum prices at which these ores may be bought or sold. Applications for permits to export to allied countries must be made through La Commission Internationale de Ravitaillement, India House.

Manganese at Butte, Montana

Manganese is abundant in most of the lodes at Butte, Montana, heretofore worked for silver and zinc. In an area of about five square miles that surrounds the principal copper mines on the north, west, and south-west, all the lode outcrops are black with manganese oxides, and in the workings that penetrate below the oxidized zone there are deposits of rhodochrosite and rhodonite, minerals containing manganese.

A reconnaissance of the Butte district was made recently by J. T. Pardee of the U. S. Geological Survey, who reports that the development of manganese ores at Butte has heretofore been wholly incidental to the production of silver, zinc, and lead, in the ores of which manganese minerals are among the chief components of the gangue. Except a few small lots used for fluxing at the smelters, no manganese ore was mined for manganese prior to 1917. As ores containing less than 25% silica are rare in the district, the development of the lodes for manganese has lagged behind that in localities which produce ore of better grade. Systematic exploration of several of the larger mangiferous lodes has just begun, and search for pockets of marketable ore is being made in a small way by several lessees.

The manganese ore is mostly oxidized and silicious, and its content of manganese ranges from 10 to 37%, but there are small quantities of high-grade ore, both oxide and carbonate. Of the higher grades of ore small bodies that contain 40% or more manganese in the form of oxides, chiefly pyrolusite, occur in most of the lodes, but this ore generally carries a rather high content of silica. At several places near the surface, however, there are pockets or lenses a foot or two thick and 10 to 50 ft. long containing less than 15% silica and 40 to 50% manganese. Other small bodies that occur in certain of the lodes contain about 40% manganese and 5 to 25% silica. These are oxidized ores, but below depths of 40 to 100 ft. the manganese oxides generally give place to rhodochrosite and rhodonite, which are found down to the limits of exploratory workings. The carbonate and silicate ores are generally intimately associated with quartz and with sulphides.

The medium-grade ore occurs in bodies that contain 20 to 37% or more of manganese. They range in length from 50 to 400 ft. and in width from 1 to 35 ft. Their minimum depths or pitch-lengths, as shown by the surface workings, range from 10 to 80 ft. Persons familiar with the deeper workings, which are not now accessible to examination, say that manganese oxides occur at one or two places to a depth of 200 ft., but that they generally give place to pink manganese carbonate at depths of 40 to 100 ft. below the surface.

Material containing less than 20% manganese forms the larger parts of many lodes. This material is probably of too low grade to be considered ore at present, but it may be regarded as a possible future resource.

Incomplete estimates of the manganese oxide ore in

the Butte district, in which Paul Billingsley and A. C. Grimes co-operated with Mr. Pardee, may be summarized as follows:

	Tons
High-grade ore, low in silica.....	1,000
High-grade ore, silicious	1,600
Silicious ore with 20 to 37% manganese.....	130,000
Silicious ore with 10 to 18% manganese.....	270,000

A common variety of the ore is rather coarse-textured, showing irregular interlocking masses of manganese oxides and quartz. Another variety is coarsely cellular, with criss-crossed partitions of pyrolusite in a skeleton or honeycomb of quartz. Ore of these varieties could perhaps be easily milled. A third kind, not so common as the others, is compact, fine-grained, and rather jaspery, and all gradations occur between the three types mentioned.

The main problems to be solved before Butte can become a factor in the manganese market under present conditions are (1) successful milling of the ores to produce a low-silica concentrate, and (2) briquetting the concentrate or otherwise making it acceptable to buyers. Milling tests have already been begun, but the results have not been entirely satisfactory, owing chiefly to losses in the tailing by sliming. Methods of concentrating manganese ore are now being studied by the United States Bureau of Mines.

LABOR has become the largest cost-factor in productive industry and seems likely to continue its relative increase. The ideal of industry is a laborer who is sober, efficient, and steady. The first is in progress of attainment by the advance of prohibition of the liquor traffic. Efficiency in the workman is attained through better management and training of the worker. Lost time is overcome by the prevention of accidents and illness, and through a great variety of means that bear indirectly, as indicated above, on the labor supply. Industrial-accident prevention looms large in the public eye through the recent enactment of compensation laws, but as a source of lost time to the plant and lost wage to the worker it is much less important than illness. Health insurance is now being urged in many quarters, and if it comes about we may expect a transfer of emphasis from accident to illness prevention. Lost time through religious holidays and other personal activities, or inactivities, of the worker is much more important than either; their relative values being something like 1, 4, and 10, in most cases. The only practicable means of dealing with the latter seems to be the offering of a bonus, over and above wages, to the workmen who lose no time each month. The underlying purpose of personnel work is to conserve the labor supply and decrease the net cost of productive labor. Personnel work is human engineering, it requires natural aptitude and special study and is not a field for the well-meaning amateur, especially the amateur who is unfamiliar with the peculiar problems of the industry in question.—Thomas T. Read, Trans. A. I. M. E.

REVIEW OF MINING

MAMMOTH, UTAH

PANAMA MINING.—TINTIC DRAIN TUNNEL.—TINTIC OUTPUT.

John E. Brown closed a contract to haul a large tonnage of uranium ore in Dry valley to the railroad at Thompsons, where a warehouse is being built to receive it.—With a view to reaching the Cardiff contact as quickly as possible, the Tar Baby has left the fissure which has been followed for some time and is driving directly east.—Fred McCoy, who has been engaged for a number of years in the development of his property at Beaver basin, on the north end of La Sal mountain, has formed the Panama Mining Co. Attention was drawn to this property during the month, when Mr. McCoy shipped a car of rich copper ore to the Salt Lake smelters. The returns showed 27½ copper and 37 oz. silver per ton. The property controlled by the new company comprises 280 acres of valuable copper claims, situated in the Beaver basin. There are large bodies of low-grade lead ore which the company intends to develop. The high-grade ore that has been mined is found at water-level in a well-defined vein. The company has a capital of \$100,000, part of which will be spent in the erection of a small mill.—The Central Standard Mines Co., operating in the eastern end of the district, has levied another assessment of ¼c. per share.—A shaft accident at the Chief Con. delayed work during the early part of the week; one of the tanks used in bailing water caught in the shaft and tore out several feet of guides.—Joseph S. Wing, of Springville, and associates are testing the oil-shale near Millfork at Spanish Fork canyon. They have located 400 acres. Herman Harms, the State chemist, is now making an analysis of the shale.—Satisfactory work is being done at the plant of the Tintic Milling Co., which treats 250 tons per day and produces 50 tons of bullion per month.—Henry Barney, who is superintending the work at the Tintic drain tunnel, says that by the first of the year the machine-drills will be operating in the face of the tunnel. Work is proceeding by hand in a loose formation.—A large engine will be erected by North Beck Mining Co. shortly. The equipment now in use is not heavy enough for deep work and consequently will be replaced with the larger hoist when the shaft reaches a depth of about 500 feet.

McCarthy & Price is shipping three car-loads of manganese ore per week from the Chief Consolidated lease. The ore carries 38 to 39% manganese and is being shipped to the steel manufacturers in Pennsylvania. McCarthy & Price has succeeded in opening a second deposit of manganese, which is about 200 ft. from the main discovery; it is possible that the ore will be found to be continuous between these two points. The deepest workings are less than 100 ft.. McCarthy & Price has leased another deposit of manganese in the West Tintic district from which shipping will soon begin.—The annual meeting of the Grand Central Mining Co. will be held at Provo on January 8 when new officers will be elected and other business transacted.—During the week ended December 22 the mines of the Tintic district sent out 197 cars of ore compared with 206 the previous week. The shippers were Dragon Consolidated 51 cars, Eagle & Blue Bell 24, Chief Con. 16, Centennial-Eureka 14, Grand Central 13, Mammoth 12, Tintic Standard 9, Victoria 8, Colorado 7, Gemini 6,

Gold Chain 6, Scranton 5, and Empire Mines 2. The combined shipments of the other nine mines makes the total of 197 cars.—The appearance of considerable water in the bottom of the shaft at the Eureka Bullion is believed to indicate that the bottom of the cave, which has caused a great deal of trouble during the last few months, is near at hand. Heavy tale is also appearing in the bottom of the shaft, along with large boulders of foot-wall material, containing manganese, barite, and iron. Small bunches of gray carbonate also are reported to be coming in and the management is confident that the work is approaching a big carbonate orebody. The shaft is down 640 feet.

TORONTO, ONTARIO

DOMES.—HOLLINGER.—MCINTYRE.—KIRKLAND LAKE. NIPISING.

The closing of the mill at the Dome Mines has been followed by the suspension of operations underground. Most of the men who have been laid off have remained in Porcupine and relieved the situation in other mines. Development, it is understood, will be resumed at the Dome in January under the contract system and will include the sinking of the shaft to the 1500-ft. level. The directors anticipate that the mill will be started again in the summer to crush some 300,000 tons of \$6 ore now in the stopes, which cannot be extracted until all the ore overhead has been broken down. This, it is estimated, will yield another 100,000 tons.—The statement of the extent and value of the orebody recently discovered in the 400-ft. level at the Millerton section of the Hollinger was received with some incredulity, and it was feared that the figures had been considerably exaggerated, but during a visit of the directors early in the month all doubts were set at rest. The vein has a width of 71 ft. with an average gold content of \$28.60 per ton.—Rich ore is being found in the lower levels of the McIntyre. The drift across the McIntyre Extension at the 1000-ft. level is in a large orebody in the Jupiter area, said to be 50 ft. wide and to carry about \$10 per ton. An electric-haulage system is being installed on this level to facilitate the handling of the ore. Extensive diamond-drill operations are in progress.—The Crown Reserve is energetically pushing the development of the Newray, where one vein 30 ft. wide is yielding upward of \$10 per ton. The mill, which is being used as a testing plant, shows a mill-head of about \$10.—The McEnaney has tapped three rich veins in cross-cutting on the 100-ft. level. Diamond drilling will be undertaken to prove at depth a 16-ft. vein supposed to be an extension of the big Millerton vein of the Hollinger.

The shareholders of the Teck-Hughes at Kirkland Lake have endorsed the proposal to raise funds for further development and the enlargement of the mill by increasing the capitalization from \$2,000,000 to \$2,500,000. The new issue of stock will be offered to the shareholders at 30c. per share.—The cross-cut of the Kirkland Porphyry on the 170-ft. level has been in ore for 22 ft.; the formation is similar to that of other mines in the camp. The shaft will be continued to the 300-ft. level.—The Teniskaming, of Cobalt, is preparing to develop the Horne and Gazelle claims adjacent to the Kirkland Lake mine.—The Canadian Kirkland has put down two shafts, one of which, at 30 ft., is on a 16-ft. vein showing visible

gold.—The Aladdin Cobalt has arranged to use the mining plant of the Sylvanite for carrying on underground work on the Burnside property, which it acquired recently.—Most of the machinery for sinking the shaft at the Elliott below the 300-ft. level is in place. The vein, which is probably a continuation of the Kirkland Lake vein, is 12 ft. wide on the 300-ft. level with ore of commercial grade.

The Mining Corporation of Canada has started to develop the claim recently secured in the new camp of Rickard township. A mining plant will be erected as soon as possible, and two diamond-drills are on their way to the property. The surface showings are rich and the veins are of considerable size.—At the Murray-Mogridge mine, at Bourkes Station, the drift of the 200-ft. level is in 120 ft., the vein continuing a good width with high gold content. The fault, found on the upper level, has been cut on the 200-ft. level.—During November the Nipissing mined ore of an estimated value of \$305,572, and shipped products from its own and customs ores of an estimated net value of \$331,196. The production for the year will establish a new high record, the total value of the output for the first eleven months being \$3,018,280, as compared with \$2,920,714 in 1913, the banner year in the company's history.—The shareholders of La Rose Consolidated, the holding company, with an American charter, have authorized its dissolution and the distribution of the assets of the company, consisting of the shares in La Rose Mines, the operating company, among the shareholders. The capital will be reduced from \$6,000,000 to \$1,500,000 and the exchange will be made share for share.—The McKinley-Darragh has closed the re-grinding and flotation plant for treating tailing for the winter. It is proposed to substitute tube-mills for the present re-grinding equipment.—The re-modeled mill of the Provincial is giving good satisfaction, the tailing from the dump yielding 12 to 14 oz. of silver per ton. The mine has an extensive tonnage of medium and low-grade ore blocked out.

HOUGHTON, MICHIGAN

ISLE ROYALE.—MICHIGAN.—MOHAWK.—OSCEOLA.

The transfer of the railway service for the Mohawk and Wolverine mines, between the mines, mills, and smelters, from the South Shore subsidiary interests to the Copper Range interests, was concluded last week and the Copper Range now handles the business. This was one of the biggest railway deals that has taken place in the copper country for a number of years.—Nothing more is heard of the rumor of the absorption of the Isle Royale by the Calumet & Hecla. Now that the stock can be purchased in the open market for \$21 per share, it would seem to have been a bad error in judgment if the Calumet & Hecla had agreed to pay twice that figure. Today Isle Royale is operating on a larger ore-tonnage basis than ever before, and is maintaining its underground openings substantially. With a normal market condition and a normal copper price and production price Isle Royale would be attracting as much attention as any other mine in the district.—A 1000-ton test of the Michigan stock-pile showed 20 lb. per ton, not counting mass copper. It is believed that the rest of the stock pile will show just as good results. Underground openings in four different places are being carried forward, showing a good class of formation.—Franklin is sinking to the 18th level on No. 2 shaft. The best ore is coming from the Pewabic lode to the north where a good shoot apparently is opening. Ore tonnage continues 1000 daily.—Lessees of the Winona are getting out 420 tons per day, mostly from King Phillip No. 1, but some from 3 and 4 Winona proper. The mill is handling 150 tons per day from South Lake.—At Mohawk, December likely will show an increase both in ore tonnage and in copper output. New ground opened in No. 1 shaft is better than it has been for some time past. Cross-cuts to the west show a series of small amygdaloid

formations that are so good they are being investigated. Mohawk is shipping 2200 tons daily; Wolverine 1200. Wolverine has re-modelled its shaft-houses to accommodate the 50-ton cars now in use.—The Phoenix is the only property of the Keweenaw that has been operating for several years. When work suspended a few weeks ago it was understood that the suspension was temporary. But the pumps are being removed, which looks like permanent abandonment.—The most important news item of the week at any of the Osceola mines is the notable increase in ore output at the Kearsarge mines. Osceola now has a larger force than at any time during the year. For a week steady they got out 110 cars of ore per day, 3750 tons average from the Kearsarges; No. 3 North Kearsarge is showing a steady increase.—Locomotives for use underground at the Calumet & Hecla are helping to care for the trammer shortage, and the tonnage will soon be over 10,000 per day if present increase is maintained.—At South Lake the ore is running 18 lb. per ton and the Butler lode, which is being stoped from three places, is showing a lot of nugget copper.

PLATTEVILLE, WISCONSIN

VINEGAR HILL ZINC.—NATIONAL SEPARATING.—GRASSELLI CHEMICAL.

William N. Smith, general manager for the Vinegar Hill Zinc Co., says the labor situation at present is much improved; negroes have been introduced into the southern districts of the field and applied to common labor and shoveling at the mines, which has tended greatly to release the more experienced for the better classes of mine work.—At the Meloy mine, owned and operated by the Vinegar Hill, electric mining-shovels are employed, which, it is claimed, are doing the work of 20 men.—At the Jefferson mine, in the Hazel Green district, a newly developed property and now fully equipped, a heavy overflow has been struck and the pumps are lifting 2100 gallons of water per minute. The mine is about drained and underground work will be in full swing before the first of the coming year. A new 800-gal. Pomona pump is being placed in the main hoisting-shaft. Double-compartment self-dumping cages are used for hoisting and 1½-ton cars will be used underground in connection with electric shovels. An exceptionally good showing is being made by the Vinegar Hill at both the Graham and North Unity mines, in the Galena district, where colored labor is largely employed.—In the Mifflin district the Yewdall and Senator mines are operating steadily with about 100 men, making a daily recovery of from 55 to 70 tons of zinc concentrate. The Rundell orebody, fully proved on adjacent lands by drilling machines, will remain undeveloped until market and cost conditions are more favorable. The company is engaged in joint drilling operations with the Grunow Mining Co., on the east boundary of the Senator lease. Several drills are employed at the company's mines in the Benton district, but strikes have been few except on the Copeland lease near Shullsburg.

The National Separating Co. of Cuba is handling 200 tons of raw concentrate every 24 hours averaging 29.32% of zinc. This yields 100 tons of finished blende ore assaying 60.54%, the bulk of which is sold in open market to the highest bidder. Shipments are made weekly to the Illinois Zinc Co., Grasselli Chemical Co., and the American Zinc Co. of Hillsboro, Illinois. A new Cottrell electric dust precipitator is being installed. Warehouses, machine shops, assay laboratory, and truck garage have been added to the big plant during the month. The Vinegar Hill Zinc Co. is giving employment to 500 men. The completion of an industry spur into the New Diggings district the first of December proved immediately beneficial to both the Meloy and Blackstone mines of the Vinegar Hill group and a big saving is effected in transportation of supplies and zinc ore.

THE MINING SUMMARY

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—The new machinery at the Arizona Bisbee Copper Co. is now ready for operation, and sinking will commence immediately.

Bisbee, December 15.

MOHAVE COUNTY

(Special Correspondence.)—It is announced that the Schuykill Mining Co. has accepted an offer to take over the Tennessee mine and that operations will commence immediately to open the orebodies that pass from the Tennessee into the Schuykill ground.—A new company, the Standard Minerals Co., has taken over the Telluride Chief Mining Co. The ore is gold, silver, and copper, and carries some molybdenite.—The 64 claims of the White Hills Mining Co. are to be auctioned to pay a debt of \$1200.—Active work has commenced on the Gold Road Bonanza. A station is being cut at the 500-ft. level.—A consolidation of the Liberty Bell Gold Mining Co. and the White Chief Mining Co. has taken place. Machinery from the Liberty Bell has been moved to the White Chief and a cross-cut toward the vein at the bottom of the 125-ft. shaft will be driven.—The Gold Ore is deepening its shaft another 150 ft. in order to further develop the orebody opened up in the levels above. A tramway has been erected between the mine and the Gold Road mill, where its ore will be treated.—The first cross-cut through the recently discovered orebody of the Grey Eagle vein on the Tom Reed has been completed at 180 ft. from the point of discovery, showing 20 ft. of ore. It is estimated that the December production will be \$60,000.—A splendid strike of ore has been made on the Morning and Evening Star mines 24 miles west of Kingman.—Lessees on the Jamison mines in the Layne Springs section are shipping ore running as high as \$100 per ton in gold, silver, and copper.—While straightening out the shaft between levels of the Walkover mine a fine body of ore running better than \$50 per ton has been opened.

Kingman, December 22.

PIMA COUNTY

(Special Correspondence.)—A. W. McChen, of New York, representing Morgan and Frick interests, has taken an option on the Silver Queen group of claims, 35 miles north of Tucson, and has commenced drilling.—Roos & Tovote have purchased the smelter at Socorro, New Mexico. The smelter will be dismantled and shipped to Tucson, where it will be erected as a custom plant. It will handle 250 to 300 tons per day.—Prospectors have located extensive scheelite deposits along the range of the Gunsight mountains, near Ajo. These deposits, together with the recent discovery of gold placers in the same district, are causing a considerable rush.—Machinery for a mill to treat wolfram ores on the Canada Del Oro claims, 30 miles from Tucson, is being shipped.—The Greater Ajo copper property, composed of 64 claims, will be taken over shortly by Eastern mining capitalists.—The Stratton Copper Co., in the Old Hat mining district in the Catalina mountains, has been taken over by the Old Hat Mining Company.

Tucson, December 17.

PINAL COUNTY

(Special Correspondence.)—Water has been lowered in the old Silver King mine to the 220-ft. level. On the 250-ft. level several drifts are to be re-timbered and exploration work carried on. The company proposes to erect a modern mill and flotation plant.

Superior, December 15.

YAVAPAI COUNTY

(Special Correspondence.)—A rich orebody that is claimed to run 50% zinc, 6% lead, 2% copper, and 2 oz. silver has been opened at the Hillside mine.—A standard drilling-rig is being shipped to the Chino valley for the Arizona Oil & Refining Co.—Sulphide ore carrying 20 to 25% copper has been struck in the drift under the Maintop orebody, which is being driven preparatory to raising to the 1200-ft. level of the Jerome Verde.—Work is to commence within a few days upon the Verde Tunnel & Smelter railroad from the United Verde crushing-plant to Jerome.—A. G. Harbaugh has made an examination of the Verde Apex and Venture Hill Copper properties and, as a result, has taken half of E. L. Bartholomew's option on 100,000 shares of treasury stock. Money to develop these properties will be raised immediately.—A group of 10 claims, called the Old Corkscrew, in Pine Flat, near Goodwin, has been purchased by J. A. Peacock of Fort Worth, Texas. The Circle Park Mining Co. will be formed to operate these claims.—The compressor at the Abe Lincoln Copper Co. is in place; the 190-ft. shaft will be sunk to the 500-ft. level. A larger hoist is also to be erected.—J. R. McEwen and E. C. Evans have taken an option on the Belcher property in the Big Bug district.—The Vesuvius gold mine is being developed by R. B. McMahon, the owner.—The Copper Key property of 20 claims, in Black canyon, has been successfully financed. Sinking of a 500-ft. shaft will commence immediately.—The Big Copper Chief just south of Bumble Bee has also been financed.—New machinery is being erected at the Ada C. molybdenum mine north of Wickenburg, preparatory to sinking the 60-ft. shaft another 300 ft. The ore is wulfenite and is reported as averaging 5 1/2% of MoO₃.—The gravity tramway from the Wildflower mine of the Crown King to the Bradshaw Development Co. mill is completed.—The Grey Eagle mill in the Mars district will be running as a custom mill shortly.

Prescott, December 24.

YUMA COUNTY

(Special Correspondence.)—A strike of copper ore has been made in the winze on the Mars claim at the Jerome Wendon Copper Co., at a depth of 62 ft. It is claimed there is 1 ft. of 11.5% copper ore. A car of good-grade ore was recently shipped from a parallel vein on the Mescal claim.

Bouse, December 15.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—The Fremont Con. Mining Co., of Drytown, has started to sink its main shaft an additional 200 ft., to the 2900-ft. level. Prospects are excellent on the 2700-ft. level for a continuance of ore in paying quantities at

greater depth. Wales Palmer is the superintendent.—Sinking is in progress at the Old Eureka property, the intention being to put the shaft down 1000 ft. below the 2165-ft. level. From the 1600-ft. level down the new company has enlarged the shaft to conform to three compartments above and good headway is now being made in the new ground. The old crosscuts and drifts, particularly those on the 1200 and 1600-ft. levels, are being cleared and re-timbered. The Frakes and Goodman ranches purchased by the present company since closing the deal with Hetty Green for the mine will later be used for mill-site and tailing impounding area. T. Walter Beam is in charge of operations at this well-equipped property.—H. DeC. Richards of San Francisco has recently been appointed consulting engineer to the Central Eureka Mining Co., to work in conjunction with the superintendent, Fred Jost. Detailed mapping of the underground workings is being made for the better handling of the ore-reserve. Ore is being extracted from the 3425, 3350, 2700, and 2500-ft. levels and 30 stamps are kept in operation nearly, but not quite, paying expenses. A 1½c. assessment has been levied recently. During Christmas week, boilers, furnaces, and compressors have been repaired.

Sutter Creek, December 29.

NEVADA COUNTY

(Special Correspondence.)—With the 60-stamp Empire mill operating at capacity and 20 stamps dropping at the Pennsylvania mine, the Empire group is recording the heaviest output of its history and producing in excess of \$100,000 per month. Splendid ore is said to be coming from the 2500-ft. level of the Pennsylvania and 4600-ft. level of the Empire, with late developments in the deeper workings particularly encouraging. More than 350 men are on the payroll. George W. Starr is general manager.—At a point beneath the footwall of the Allison Ranch lode a new vein has been found on the No. 2 level of the Allison Ranch mine. The discovery was made in the south-west drift by lessees. The shoot averages 10 in. wide, assaying \$30 per ton in free-milling ore. Careful prospecting shows the shoot persists to the seventh level, the deepest point to which the water has been lowered. Twenty-five men are working on company account, and several sets of lessees are active. The mill is running two shifts. W. Harvey, the superintendent, is proceeding with unwatering the shaft to the 1700-ft. level.—The Grass Valley Deep Mines Co., composed of Nevada and Colorado people, has taken a bond and option on the Alaska-Pen Franklin group of quartz claims, situated seven miles south-west of Grass Valley. Extensive work is to start immediately with Thomas W. Hosanko as superintendent. Some good ore has been exposed near the surface.—Considerable activity is reported from Moore's Flat, above Nevada City.—At the Gold Canyon developments are proceeding and good ore is exposed. W. H. Griffith is superintendent. A. Fitzerald, the superintendent, is pushing work at the Fruitvale group. A large vein of profitable ore is reported exposed.

Grass Valley, December 31.

SHASTA COUNTY

(Special Correspondence.)—The Mountain Copper Co. is preparing to erect a large cyanide plant at Minnesota station, midway between the Iron Mountain mine and Keswick. The plans are drawn and material for the building is on the ground. The cyanide plant will be used to save gold and silver from ores that run high in those metals.—Neeley Brothers' chrome mine, 17 miles west of Castella, is making shipments of chrome. Thirty-five mules pack the chrome three miles to the end of the wagon-road, where auto-trucks are loaded for completing the transportation to the railroad.

Redding, December 27.

(Special Correspondence.)—G. C. Taylor has taken a two-year option on the Donkey copper property, near Ingot. The

option provides that a royalty of 10% shall be paid on ore running below and 15% on ore above \$35 per ton. The property was worked several months by the Mammoth Copper Co., and is stated to contain much ore of shipping grade.—High-grade shipping ore has been uncovered on the 1000-ft. level of the Anchor mine, one of the properties comprising the Bully Hill group near Delamar. The deposit was opened through the Rising Star shaft. Steady shipments are being made to the Kennett smelter, and local stockholders state it is probable that a large flotation unit will be erected next spring, and possibly an electrolytic zinc plant, similar to the one operated near Kennett by the Mammoth Copper Co. All ores of this district carry a heavy proportion of zinc.—Shipments of silicious copper-silver ore are going to Kennett from the Silver King mine, near Redding; the product comes from a dike 70 ft. wide and upward of a mile long. Considerable prospecting has been carried on and preparations are being made for deeper developments. San Francisco and Montana people are chiefly interested. L. E. Parker is manager.—The Gardella Dredging Co. has practically completed No. 2 dredge and expects to build two more in 1918. The holdings are situated on Clear creek, a few miles below Redding; No. 1 dredge has been operating two years at an excellent profit. The owners plan to reclaim much of the dredged area and devote it to agriculture.—J. A. Wilson and associates have arranged for extensive prospecting of dredging ground near Gas Point. The Shasta Dredging Co. has been working profitable territory in the district for several years. The new area is owned by the Drew estate.

Kennett, December 23.

SISKIYOU COUNTY

(Special Correspondence.)—New lessees are re-opening the Rancherie gold mine, one mile and a half from Hornbrook, and adding new machinery. The local power company is erecting a power-line from Henley to supply the mine with electricity.—John Ritz of Etna who has been operating the Advance mine in the Forks of Salmon district has reduced his working force until the spring.—John Traverse of Etna Mills is operating the Mercury American Co.'s mines at the head of Beaver creek.—Much progress is being made with the new equipment erected on the Know Nothing gold mine, near Forks of Salmon, under the management of W. R. Beall.—The Dewey gold mine, re-opened last summer after ten years idleness, is operating a ten-stamp mill and auxiliary machinery, driven with electric power. Recent development has uncovered a vein ranging from 10 to 20 ft. wide.—The California Bar placer mine, near Crox, owned by the Vina California Bar Co. of Oakland, has resumed operations under the management of H. J. Croy.

Hornbrook, December 27.

TRINITY COUNTY

(Special Correspondence.)—A vein ranging from 10 in. to 3 ft. wide has been discovered by R. H. Bailey on Maple creek, about four miles from Junction City. The ore contains gold and a little platinum. Mr. Bailey states he has traced the vein 3000 ft. and that much rich ore is exposed. Several claims have been located and development begun. Numerous placer mines were formerly working in this district.—Prospecting of dredging territory continues active along the Trinity river and tributary streams, and much new exploratory work has started along the Salmon river and into Siskiyou county. The Pacific Gold Dredging Co., a Guggenheim subsidiary, is reported interested. Several fairly rich deposits have proved unsuitable for dredging because of presence of numerous huge boulders and heavily cemented gravel. The Pacific Dredging Co. attempted to work deposits of this character in Morrison gulch, but was forced to abandon the enterprise and move its dredge to a point near Carrville. Several companies are now trying to devise a satisfactory method for economical working

of the refractory deposits.—The Oakland owners of extensive asbestos deposits near Cinnabar are planning to operate next spring. The mine is provided with a good plant and is connected with Castella, the nearest railroad point, by an excellent road. A large deposit of asbestos is exposed, much of it being of fine quality, according to the management. The indebtedness of the company has been liquidated and the treasury strengthened.—The Testy, La Grange, Hupp, and other hydraulic mines near Weaverville are active, and several small properties near Lewiston, Douglas City, and Junction City have been placed in shape for an active season. The outlook is favorable for a good year. Particular attention is being paid to recovery of platinum, which occurs in small quantities in the gold-bearing gravels. Representatives of the U. S. Geological Survey have recently advised local operators concerning the importance of recovering platinum.

Weaverville, December 30.

COLORADO

SUMMIT COUNTY

At the new molybdenite mining camp of Climax, situated on the South Park line of the Colorado & Southern railway near Fremont's pass, the American Metal Co., of New York, has almost completed a 250-ton concentration mill for the purpose of making a marketable grade of concentrate from the large body of low-grade molybdenite ore held by the company. Since August 1, about 130 men have been employed in the construction of the mill, boarding houses, necessary mining structures, and two aerial tramways, and in doing development. The mill is situated on a spur track from the railroad at an altitude of 11,300 ft. The mine is about a mile farther up the mountain. The deposit of 1% molybdenite ore outcrops about 800 ft. above the mill. The ore for the mill will be dumped into receiving bins at the mine, and from these will be taken by a two-bucket aerial tramway 500 ft. long, to crusher-ore bins at the foot of the hill. After being crushed the ore will be elevated to other ore-bins by a belt-conveyor, from which it will pass over a Leschen tramway 5000 ft. long to the receiving-ore bins of the mill. The ore will be ground in ball-mills and will then be concentrated in Callow and Janney flotation-machines, the concentrate being de-watered on a Portland filter. The mill will have a capacity of 250 tons per 24 hours. The mill and bunk-houses will be steam-heated. It is expected that the plant will be in operation by the end of February. The large body of molybdenite, running from $\frac{1}{2}$ to 16%, promises a steady supply. Recent sales of 60% molybdenite are reported as having been made at \$48 per unit.

The committee named by the Colorado legislature last winter, headed by Siewers Fincher of Breckenridge, to make a complete and exhaustive survey of the smelting industry of the State, in order to give the ore-producers information and data upon which they could figure with accuracy, and which would enable them in the future to deal intelligently in making contracts with the smelters, has completed its work. The investigation has been complete and thorough. O. R. Whitaker, a trustee of the Colorado School of Mines, was secured to take charge of the technical work. His report is replete with charts and tables. The law establishing the committee unfortunately did not provide funds sufficient for the publication of enough of these reports to fill the demand, but they will be made to go as far as possible and early applicants probably can be supplied. The Smelter Investigation Committee has offices in the Capitol building, Denver.

TELLER COUNTY

(Special Correspondence).—Thrift or war savings stamps took the place of gold coins for Christmas donations to employees by mining and leasing companies of this district this year.—The second discovery at the 500-ft. level of the Empire State shaft has been made by the lessee, Yakov & Co.,

on the rich Maloney vein. The shoot opened up for 15 ft. to date is making rich screenings. In the core of the Maloney vein a six-inch streak of fluorite and quartz carries large crystals of calaverite and is good for 100 oz. gold per ton.—Shipments have been resumed from the Wild Horse mine of the United Gold Mines Co. on Bull hill. Carl Evans, superintendent, has opened up a strong body of milling ore at the 500-ft. level of the Gleason shaft and is shipping two cars per week to the Golden Cycle Mining & Reduction Co.'s plant at Colorado Springs.—A new and rich discovery has been made on the Shoo Fly, a Stratton estate property on Womack hill, just beyond the eastern boundary of this city, by Simms Allbaugh & Willis, lessees from the Stratton estate. At a point about 70 ft. west of the Hickman discovery and at a depth of about 75 ft. from surface, the lessees are mining between 2 and 3 ft. of quartz carrying rusty gold and making screenings that will ship at close to five ounces gold per ton.—A new lease covering a three-year term has been secured from the Free Coinage Consolidated Co. by L. F. le Brun of Cripple Creek, with whom is associated F. H. Phillips of New York, on 1300 ft. of the Wilson lode. The lessees are driving into the leased ground from the 800-ft. level of the Lee shaft, giving them 400 ft. of virgin ground under the Murphy, Mercer, Reed, and Van Tilborg stopes on the Wilson, from which big money has been made by the different lessees named.

Cripple Creek, December 24.

IDAHO

LATAH COUNTY

The Luella mica mine, at Avon, has been sold by Arthur A. Booth of Spokane for \$30,000 to a syndicate of Seattle, North Dakota, and Minnesota men that has organized the Idaho Mica Co., with capital of \$500,000. The officers are John Patterson, president; John A. Soboe, vice-president; H. G. Otis, secretary; and H. S. Yarrow, treasurer. It is said that a quantity of mica is exposed in the Luella adit. Production was begun 20 years ago and a carload shipment was made to San Francisco before the fire.

SHOSHONE COUNTY

The Caledonia Mining Co. of Kellogg will pay \$78,150, at the rate of 3c. per share. The Consolidated Interstate-Callahan Co. will pay 5½c. per share, one-half its former quarterly rate. The disbursement will total \$232,495.—The Douglas Mining Co. will pay 7c. per share for the first quarter. The payment will amount to \$6400.—The Hecla Mining Co. paid 5c. per share, amounting to \$50,000, making a total for 1917 of \$1,600,000, and a grand total of \$6,305,000.

NEVADA

CLARK COUNTY

(Special Correspondence).—Development of the main ore-body on the 700-ft. level of the Yellow Pine is being pushed vigorously. The orebody has been opened for over 200 ft. on its strike and shows shipping ore throughout. The winze from this level has cut, at a depth of 40 ft., an orebody nine feet thick, assaying 48% zinc. From the 900-ft. level cross-cutting is advancing to tap the main vein and should attain its objective within three months. The mill is running at full capacity and tailing from the slime pond is being dried and shipped. In the present year dividends totalling \$360,000 have been disbursed. There remains in the treasury \$100,000 in cash, and \$75,000 represented by Liberty bonds.—The Manganese Association has started shipments to Salt Lake, and expects soon to be in a position to produce 200 to 300 tons of ore per day. Numerous ore-buyers are in the district, and several claims adjacent to the producing group have been examined. The property is a few miles from Las Vegas.—The winze from the adit in the Oro Anigo is down 65 ft. and has been in ore for 35 ft. The shoot ranges from 8 to 14 in

wide and is high grade. Copper, silver, and gold occur in the ore together with a little platinum. Preparations are being made for occasional shipments, and for further development. Sam Yount is manager.—Dedrich Bros. have made a promising discovery on the property of the St. Anthony Mining Co., near Goodsprings. The vein ranges from 12 to 24 in wide and occurs in ferruginous formation. The ore is stated to assay 45% copper in the form of copper glance.

Goodsprings, December 23.

ESMERALDA COUNTY

(Special Correspondence.)—The second payment on the indebtedness of the Florence-Goldfield company has been made to creditors, and Harry B. Clapp, the receiver, expects to make the final payment on or before January 15. Immediately upon recovering control of the property the owners will arrange for re-organization of the company and resumption of work, according to advices received here by stockholders. The Dell Hammond-Charles Taylor lease is developing rich ore and reports net earnings of \$15,000 in a brief period. A number of lessees are operating on Florence ground with good results.—The cyanide and flotation units of the Goldfield Consolidated are treating approximately 32,000 tons per month, divided about equally between mine-ore and tailing from the old mill-pond. In October, 15,975 tons of the latter was re-treated, netting \$5800. In the same period 15,900 tons of ore yielded net profits of \$15,043, making a total earning of \$20,843.—Developments on the 1350-ft. level of the Grizzly Bear are claiming interest, with ore ranging from \$9.60 to \$10.35 per ton coming from two working-faces. The orebody recently discovered in the Aurora Consolidated, at Aurora, is stated to be developing satisfactorily.—The winze from the main drift on the 880-ft. level of the Jumbo Junior has exposed a shoot 18 in. wide, reported to assay \$50 to \$150 per ton in gold, silver, and copper, with silver predominating. The discovery was made near the hanging wall and prospecting is proceeding to determine extent of the shoot. A shipment is being prepared. Connections have been established between the northern workings and the main south drift of the Kewanas mine.—J. J. Jordan and Edward Yeiser have appealed to the Supreme Court from an order issued by Judge Walsh, restraining them from disposing of their interest in the Life Preserver group of gold claims at Tolicha. They are said to have agreed to sell the property to Zeb Kendall for \$120,000. Dave Ward secured the restraining order, claiming he held a one-third interest.

Goldfield, December 22.

MINERAL COUNTY

(Special Correspondence.)—Development on the 250-ft. level of the Nevada Rand, near Rand, has proved encouraging, with the new vein developing well: 20 tons of ore averaging \$100 per ton has been shipped, and an 8-in. shoot assaying \$1675 in silver and gold has been uncovered. The management is preparing to drive from the 350-ft. in expectation of cutting the vein at this point. A mill is planned, as upward of 35,000 tons of \$15 ore has been blocked out.—The Reservation district, a few miles from the station of Reservation on the Goldfield branch of the Southern Pacific railway, is attracting considerable attention, with silver-lead, gold, and copper deposits occurring. The Packsaddle is being placed in shape for production, and sinking of a new shaft at the Reservation Hill will start shortly to open promising ore in new territory and avoid the water which forced suspension of operations in the old workings. The June Bug is active, and the Sebastopol is being placed in shape for steady work. The Mountain View has produced some good ore this year; the mill has been in operation for several months.

Luning, December 29.

(Special Correspondence.)—The Calavada Copper Co. has erected an air-hoist on the 1000-ft. level of the main shaft and

will continue sinking the winze, which is now down to the 1100-ft. point, to the water-level; this, it is expected, will be reached in the next 200 ft. It is believed that the primary sulphides will be found at the water-level and also secondary enrichment from the re-deposition of the values that have been leached from the oxidized ores above. High-grade ore has been found from the surface down and at the 1000-ft. level there is ten feet of oxidized ore averaging better than 15% copper, with residual bodies of chalcocite that go 50%.—The Kirchen Mines Co. is shipping from three ore-shoots in the lower adit of the St. Patrick mine, the third having been opened during the week.—The three new finds which were recently made in the mines of the Pilot Copper Co. are holding their own as development proceeds. The first two were in the Champion mine, at the 150-ft. level, and the third in the big vein of the Anderson mine.—The face of the drift on the electrolytic claim of the Congress Copper Co. is still

PART OF NEVADA AND CALIFORNIA

in ore that averages 5%, while the adit on the Neversweat claim is making good progress and will soon reach the downward extension of the rich orebody that was glory-holed at the surface.

The last two carloads of ore shipped by the Pilot Copper Co. from Luning returned \$1132 and \$1209, respectively, after deducting freight and treatment charges. Three important finds were made during the week. The first was in the Champion mine in a raise from the 150-ft. level where a hitherto unknown vein carrying 3 to 10% copper was cut. The second was on the same level about 500 ft. distant. In a cross-cut going through the heart of a low-grade orebody a face of carbonate ore 7 ft. wide and 8 ft. high was exposed which averages 4% copper. The third was in the Anderson mine where the hanging wall of a 28-ft. vein was reached. The last 8 ft. of this vein averages better than 4%.—In an east drift on the Electric claim of the Congress Copper Co. the last 26 ft. has been in ore averaging 5%. On the company's Neversweat claim an adit is being run to get under the old glory-hole from which so much rich ore has been shipped.—At the Luning Idaho mine, in addition to the usual work, an adit has been started in Erickson gulch which will tap the orebody developed in the Stockham adit at 100 ft. greater depth. It is probable that this can be run in ore the entire distance.—The Kirchen Mines Co. is maintaining steady shipments of high-grade ore from its St. Patrick mine, the

stopes on the lower level are furnishing the bulk of the ore now going out.

Luning, December 24.

WASHOE COUNTY

(Special Correspondence.)—A new large Cameron station pump has been ordered for the Nixon-Nevada mine, and as soon as it is in place a winze will be started on the No. 1 vein at a point about 100 ft. from the cross-cut. Here is an unusually good showing, with bunches and streaks of almost pure chalcocite in the oxidized ores. Stopping in good ore is in progress on the No. 2 vein, the present workings being about 75 ft. from the cross-cut. It is evident that the mineralization from the No. 4 vein extends much farther into the wall-rock at the lower level than from the other veins. The cross-cut still shows lots of iron and copper stains, but recent surveys show that it will have to be run considerably farther before the vein is reached.—The drift on the No. 1 vein is now out 350 ft. from the cross-cut and a raise is to be put up near the face to explore the new orebody. This is the second ore-shoot that has been found in the north drift, the first being 200 ft. long and the ore high-grade. The north drift on the No. 2 vein is out 100 ft. and is also in high-grade ore. The main cross-cut still shows copper stains and small stringers, but has not yet cut No. 4 vein. The new six-foot vein which was recently opened by surface trenching looks especially good.

Copperfield, December 22.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Oaks Co. is working through its new main Central shaft. Levels are being run to connect with the lower working of the Maud S. mine and as soon as these are completed ore will be extracted through this shaft. Development and ore-breaking continues in the Pacific, Maud S., and Eberle mines.—Material is coming in rapidly for the new Socorro Mining & Milling Co.'s plant. Construction work is progressing at mill and mine. It is understood that the mill will have a considerably increased capacity and will be modern in every way.—This has been a big year for the Mogollon district. Tonnage in the various mills has been up to capacity and, while the figures are not yet available, the total production will be large. Development in the lower levels of some of the deepest work in camp has opened up good ore and the mineral discovered within the year and the new mines opened, places the Mogollon district well in the lead of the silver-gold camps of the South-West.

Mogollon, December 26.

OREGON

JACKSON COUNTY

(Special Correspondence.)—Harvey J. Saltee, who recently bonded the Barron gold mine east of Ashland from the Alton Mining Co. of Ashland, has closed down the mine for the winter and left for his Reed mine in Shasta county, California. He has spent \$6000 in re-opening the Barron mine, but the late heavy rains have made the roads impassable between the mine and railroad. During the operation five car-loads of ore were shipped to the Mammoth Copper Co. smelter at Kennett, which assayed 1 oz. of gold to 20 oz. of silver, with some zinc and lead. The high-grade ore assayed \$75 per ton in gold and silver, while the low-grade \$10 to \$15. There is 1000 ft. of drift in the mine, one main drift and some prospects. The lessee thinks well of the property, although it presents some difficulty in the way of economical operation. Under the conditions this fall the haul to the railroad, a distance of seven miles, cost \$5 per ton, while the difficulty of placing a mill at the mine is that water is only available six months in the year.—Much progress is being made in developing and operating

the Chisholm cinnabar mines, 12 miles north of Gold Hill. W. P. Chisholm, the owner, reports that he will put in crushers and concentrating machinery next spring to operate with his 12-pipe furnace. L. P. McConiche, of Tacoma, representing people of that city, is developing the Buena Vista group of cinnabar mines, recently purchased from W. S. Webb of Medford. This property is just over the Jackson county line in Douglas county, and is an extension of the mercury-bearing dike that extends through Jackson county from California.

PART OF OREGON

The property will be fully equipped with furnaces next spring.—Extensive work is being done at the Greenback gold mine in the north end of this county. The old equipment is being dismantled in order to erect new machinery during the coming season. The 7000-ft. aerial-tramway has been sold and is being removed to equip the State limestone-fertilizer plant at Gold Hill.—The late rains have set the placer mines through southern Oregon and northern California in operation, and from present indications the coming season will be a successful one. Considerable attention will be given by the operators to save platinum, which formerly went to waste.

Gold Hill, December 27.

WASHINGTON

STEVENS COUNTY

Cross-cuts are proceeding in two directions from the bottom of a 175-ft. shaft in the property of the Silver-Antimony Mining Co., Chewelah. The west cross-cut, which has been driven 100 ft., has penetrated 40 ft. of mineral that is marked with ribbons of ore containing silver and copper, some of it in the native form. The east cross-cut, driven 45 ft., is directed at a body of silver and antimony four feet wide at the surface. The directors of the company are J. J. Wells, president; J. Kuntz, vice-president; and Harry W. Hofer, secretary-treasurer. Uniontown; J. J. Schoenberg, general manager, Chewelah, and C. W. Schlee, Walla Walla. Harry Dudman is the Spokane representative.

SPOKANE COUNTY

Shipments by the Knob Hill Co. are proceeding at the rate of a carload of ore every third day. The grade is \$9.50 per ton, and the production is about paying the expenses. The

source of the ore is a section of the vein 18 to 24 in. wide on the 200-ft. level of the shaft workings. More or less rock becomes mixed with the ore in breaking, which explains the low grade of the product. The drift lacks about 200 ft. of attaining the point where ore of better grade was found on the level above. Operations are being confined chiefly to a raise from the 200-ft. level. A little ore is being broken in a stope started north of the raise. The advance of the raise, which is to be connected with a winze, is handicapped by water. Until the raise is completed and ventilation provided little work can be done on the new level. Fourteen carloads of 50 tons each were shipped to the Tacoma smelter in November.

CANADA

BRITISH COLUMBIA

The strike of men employed by the Consolidated Mining & Smelting Co. at Trail, has been called off, according to a report from Trail received December 20. One thousand men, it is estimated, returned to the plant and the remainder will return as soon as places can be found for them. It is believed the Consolidated company will issue an order for the resumption of operations on its properties at Kimberley, Rossland, Eholt, and elsewhere in British Columbia, which were suspended when the strike was called on November 15. The number of men affected is said to be from 6000 to 7000, including those employed at Trail. The tonnage released is 8000 to 10,000 per week, of which about 10% is from mines of Washington.—The suspension was not total in mines outside of those owned by the Consolidated. Operations were maintained with reduced forces on several properties. A large tonnage of lead ore has been accumulated, but zinc ore was sold in the United States by several corporations in the interim.

Obituary

FRED TURREL GREENE, mining engineer and geologist, was killed in a motor accident at Butte, Montana, on Christmas day. He was born at Brooklyn, New York, 43 years ago; he graduated from the University of Toronto in 1893 and from the Michigan College of Mines in 1897. Immediately thereafter he entered the engineering department of the Boston & Montana company at Butte, and a few years later he became assistant to Horace V. Winchell, then geologist for the Amalgamated Copper Co., this association with Mr. Winchell continuing to the end, for at the time of the fatal accident he was working with Mr. Winchell as a geological expert in the litigation between the Elm Orlu and Butte & Superior companies. His untimely death was a great shock to the mining community of Butte, where he had been socially prominent and generally liked as a sincere, honest, and thoroughly capable engineer.

JAMES W. MALCOLMSON died suddenly on December 26 at Kansas City, Missouri. He was consulting engineer to the Lucky Tiger Combination Gold Mining Co. at the time of his death and was largely responsible for the success of that enterprise, well known in Mexico as the El Tigre. He was educated at the Royal School of Mines, London, whence he graduated with honors in 1889. During the course of his career, which was honorable and successful, he served as mining engineer to the Consolidated Kansas City Smelting & Refining Co. from 1893 to 1898, as manager of the mining department of the A. S. & R. Co. in Mexico from 1902 to 1909, and since then as consulting engineer to the Lucky Tiger Combination company, with headquarters in Kansas City. He attended the recent meeting of the Institute at St. Louis in October, when he appeared to be in excellent health and spirits. His sudden end will come as a great shock to his many friends, who will join in sympathy for his wife and family.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

W. E. STEPIENS, from Vernon, B. C. is here.

CHARLES BUTTERS has returned from Washington.

HOWLAND BANCROFT is at the Engineers Club, New York.

SCOTT I. WELLMAN, of Los Angeles, is in San Francisco this week.

WALTER G. PERKINS has returned from New York to San Francisco.

THOMAS M. BAINS JR. is Major in the Engineer Officers Reserve Corps.

GEORGE E. FARISH has arrived at New York on his return from Salvador.

SCOTT TURNER is expected in San Francisco from Lima, Peru, within two weeks.

E. E. MCCARTHY is now resident manager for the Yukon Gold Co. at Dawson.

STUART H. INGRAM has returned from Nayarit, Mexico, to perform military service.

VAUGHAN M. LAVERY is Lieutenant in the Third Tunnelling Corps, Canadian Engineers.

O. B. PERRY, Major in the U. S. Engineer Reserve Corps, spent Christmas at Palo Alto.

LIEUTENANT F. J. HOLNIGMANN is now with the 62nd Infantry, Camp Fremont, California.

CHARLES S. HALEY is Captain in the U. S. Engineer Reserve Corps and is now at Camp Lee, Virginia.

C. B. LAKENAN, general manager for the Nevada Consolidated Copper Co., was here during the week.

W. H. HOWARD, metallurgist to the A. S. & R. Co. at Salt Lake City, was in San Francisco on his way to Tacoma.

EDWIN F. GRAY, consulting engineer to the Consolidated Copper Co. of Ely, Nevada, spent the holidays in San Francisco.

A. E. DRUCKER is at Baltimore supervising construction and starting of a concentrating mill for the Baltimore Tube Company.

T. ISHIKAWA, mining engineer to the Kubara Mining Co., Japan, is visiting the copper mines and smelters of Montana and Arizona.

WILLIAM B. FISHER, who is taking part, as an expert, in mining litigation at Butte, spent the Christmas holidays in San Francisco.

GEORGE B. BUTTERWORTH is returning from New York to Aroa, Venezuela, where he is manager for the South American Copper Syndicate.

J. A. THOMAS, formerly with the Consolidated Arizona Smelting Co. at Humboldt, is with the Cananea Copper Co. at Cananea, Sonora, Mexico.

ROBERT R. VAN VALKENBURGH, formerly with the Alaska Gold Mines Co., has been appointed resident superintendent for the Michigan-Utah Consolidated Mines Company.

C. A. THOMAS has resigned as manager of the Yukon Gold Co. and has been appointed assistant to E. B. BRADEN, the vice-president of the Selby Smelting & Lead Co., at San Francisco.

A. I. M. E. San Francisco

A meeting will be held next Tuesday evening, January 8, at the Engineers Club. W. J. Loring will open a discussion on 'The Economic Value of Gold Mining,' Carl C. Plehn, Professor of Finance, University of California, will continue the discussion, and E. H. Benjamin and F. W. Bradley have promised to participate. Dinner (\$1) at 6:30; meeting at 7:30.

THE METAL MARKET

METAL PRICES

San Francisco, December 31

Aluminum-dust (100 lbs. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	17.00
Antimony (wholesale), cents per pound.....	15.25
Electrolytic copper, cents per pound.....	23.65
Pig-lead, cents per pound.....	6.50—7.50
Platinum, soft and hard metal, respectively, per ounce.....	\$105—113
Quicksilver, per flask of 75 lb., respectively.....	115
Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, December 31

Antimony, 45% metal, per unit.....	\$1 00
Chrome, 34 to 40%, free SiO ₂ , bmt 8%, f.o.b. California, per unit, according to grade.....	\$0.00—0.70
Chrome, 40% and over.....	\$0.70—0.85
Manganese, crude, per ton.....	\$8.00—10.00
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.	
Tungsten, 60% WQ, per unit.....	26 00
Tungsten ore is firm, all the stock in New York has been exhausted.	
Molybdenite, per unit MoS.....	\$4.00—15.00

EASTERN METAL MARKET

(By wire from New York)

December 31.—Copper is fairly active at 23.50c. Lead is dull and firm at 6.50c all week. Zinc is inactive and steady at 7.87c all week. Platinum is unchanged at \$105 for soft metal and \$113 for hard.

Samuel Montagu & Co. says: The negotiations of the British and United States governments with regard to the purchase of a substantial portion

of the world's production do not yet appear to have reached a definite form. Items of news have been cabled from New York about the matter, but not of sufficient precision to enable a judgment to be founded as to the effect of this important projected step upon the eastern exchanges and the future of silver. It is stated that the United States of America produced 72,833,000 oz. in 1916, out of a world production of 172,383,000. It is anticipated that the United States will turn out at least 75,000,000 oz. in 1917, so that with improved conditions in Mexico, the world's total may approximate 200,000,000 oz. for this year. Should, therefore, the original information be correct, and an amount of 100,000,000 oz. be acquired by the Governments for delivery in 1918, this would be equal to 50% of the world's probable production, while if only the United States output be purchased, it would be equal to about 37½%. The Department of Commerce in America announced on November 28 that the silver exports during this year had amounted to \$62,234,000. There has been a considerable shrinkage, namely, 147 laos in the Indian note circulation. As regards the reserves, the silver holding was reduced by 194 laos, but the gold increased by 17 laos.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

The spot position for quicksilver is as bad as ever and little spot material is to be had. While Californian virgin quicksilver is offered at \$115 for shipment from California, the arrivals are slow and such lots as actually reach New York demand a good premium. The last business reported has been done at \$119 spot New York.

TIN

Prices in New York, in cents per pound.

Date	1915	1916	1917	1915	1916	1917
Jan.	34.40	41.76	44.10	July	37.38	38.37
Feb.	37.23	42.60	51.47	Aug.	34.37	38.88
Mch.	48.76	50.50	54.27	Sept.	33.12	30.66
Apr.	38.25	51.49	59.63	Oct.	39.00	41.10
May	39.28	49.10	63.21	Nov.	39.50	44.12
June	40.26	47.07	61.93	Dec.	38.71	42.95

Tin prices have actually reached 60c per pound, quoted for spot stocks in, but with the metal market closed from December 21 to 26 the position might undergo some change and prices can only be given nominally.

Charles Hardy says: On account of a large foreign inquiry coming in at the same time as one of our largest users at home appeared in the market, the tungsten market has been exceedingly firm during the past week and most good-grade ore in New York found ready buyers, even material on steamers shortly due was readily absorbed by the market. The tungsten price remained steady at a slight advance and \$21.50 was paid for high-grade wolframite with prices ranging lower for off-grade ore. Such scheelite as was offered was readily sold at \$26 per unit. The year closes with a firm market with a good demand and the prospects for the new year of prices continue at least on the present level if not higher.

Again an active business has been done for such molybdenum as can be delivered immediately. The demand is quite good and prices range from \$2.25 to \$2.30, according to grade.

The shipment of molybdenum largely with the regular arrivals of manganese ores and such small lots as reach New York market from time to time readily find buyers at a premium over the schedule price, which still remains at \$120, delivered at furnace, for the 48% ore.

Eastern Metal Market

New York, December 26.

The year draws to a close with all the markets inactive and with two important metals under strict Government control, namely copper and tin, and also with the prospect that lead and zinc will pass under similar regulation when the conditions warrant. In 1917 copper, tin, and lead reached higher levels than at any time during the War, but, as the year ends, all the metals are lower than in many months, with the exception of tin which now stands at the highest level in its history.

Today copper is unchanged, but moving freely at regulated prices.

Tin is still scarce and nominal.

Lead is firm, but inactive.

Zinc is a little stronger, but quiet.

Antimony is lifeless and unchanged.

In the steel market the year ends with practically an assured prospect that there will be no important changes in present fixed prices, at least during the first quarter. A proclamation by the President is expected daily which may extend the operation of the present schedule. Stocks of pig-iron have been so depleted for steel-making purposes that, as these are nearly gone, there has resulted a scramble for iron that would have sent prices sky-high but for Government regulation. The prospects are that there will have been a material increase in both pig-iron and steel production in 1917 over 1916, and the latter was a record year.

COPPER

There seems to be no reason for believing that there will be any change in the price of copper for at least three months. Continuance of the present prices is practically assured so far as steel is concerned, and it is inferred as to copper. With the market controlled absolutely as to price, sales, and distribution, and with everything subservient to war-needs, there is no chance for excitement in the market nor for any activity as in normal times. There seem to be ample supplies for most purposes, the only impediment being delays in shipments because of railroad congestion and storms. Sales are being made for first-quarter delivery of all grades of copper at 23.50c. per lb. in the larger market, and at 24.67½c. in the jobbing realms. Metal is being released for commercial as well as for war-needs, where possible, and satisfaction seems to prevail generally.

TIN

The utmost confusion and delay in the matter of import licenses continues. Some importers are in serious straits, and are decidedly discouraged. In more than one case, because of delays in the mails or for other reasons, licenses from Washington have been late in reaching New York, so that no further extensions in general orders were possible and the metal went into general stores. This has resulted, despite the utmost efforts to secure information even by cable as to incoming metal, and to comply with Government requirements as fully as possible. Tin actually has been piling up on the docks, for it cannot be accepted through the custom house until the importer obtains his license. Because of these conditions, importers are burdened also with additional expenses, and there are no prospects of transferring these to the buyer. The scarcity of all grades continues unrelieved, and the market as a whole is quiet and uninteresting. Sales of all grades for all positions have probably averaged only 50 tons per day for the last week. These have been mostly prompt shipment from England and far futures. Spot Straits is again nominal at

\$5 to \$6c. per lb., New York, with none offered. Some quote even a higher nominal level. Arrivals to December 21, inclusive, have been 1225 tons, with 4400 tons reported afloat. An advance of £4 10s. per ton has been recorded in the London market for spot Straits. The quotation on December 21 was £309 10s., as compared with £305 on December 19, these being the latest cables published.

LEAD

The moderate easiness referred to a week ago in the lead market, resulting in a slight recession in prices, with sales at 6.40c., New York, has disappeared. The market is now firmer at the old level of 6.50c., New York, or 6.35c., St. Louis, for early delivery. This is not explained as due to a more active demand, but as induced by an unwillingness of sellers to part with metal not under contract, since they are apparently well booked with orders. The American Smelting & Refining Co. still quotes 6.25c. per lb., New York. The congestion on the railroads is a decidedly disturbing factor in both lead and zinc and no relief is apparent. Early last week considerable export business is reported as put through, and there are negotiations on foot for more.

ZINC

The market is a little stronger than a week ago, with prime Western for early delivery quoted today at 7.75c., St. Louis, or 8c., New York, but with no sales at these levels to establish this price. The better tone is attributable to the announcement of the bids on 1000 tons of grade C zinc for the Government, referred to last week. These were higher than expected, and ranged from 7.87½c., New York, to 8.60c., New York, with the New Jersey Zinc Co. as the low bidder. Grade C is only slightly better in quality than prime Western. On Saturday, December 22, bids were also taken on 4000 tons of the same grade for the Army, but these had not been made public at this writing. This disclosure is awaited with interest. In general the market is quiet, with few sales in any quarter reported, and not much inquiry. Future deliveries are quoted at ½ to ¾c. higher than the levels for nearby metal.

ANTIMONY

Chinese and Japanese grades are unchanged at 15c. per lb., New York, duty paid, for spot or early delivery. The market continues dull and uninteresting.

ALUMINUM

The market is without interest at 36 to 38c. per lb. for No. 1 virgin metal, 98 to 99% pure, for early delivery.

ORES

Tungsten: The market is regarded as a little firmer, with slightly higher prices paid for wolframite, the better grades bringing \$24.50 per unit in 60% concentrates. Scheelite has again sold for \$26 per unit. A good demand from a large domestic consumer, combined with large foreign inquiry, has contributed the better tone to the market.

Molybdenum and antimony: At prices varying from \$2.25 to \$2.30 per lb. of MoS₂ in 90% material active transactions are reported the past week. Antimony ores are nominal at \$1.75 per pound.

Manganese ores: For domestic ores a leading Eastern dealer quotes as follows: \$1.20 per unit for ore containing 50% or more of manganese; \$1.10 per unit for ore averaging 46 to 49.99%; \$1 per unit for 42 to 45.99% ore; and 90c. per unit for 38 to 41.99% ore. For all these grades maximum limits of 10% silica, 0.20% phosphorus, and 3% iron are stipulated. For Brazilian ore \$1.10 to \$1.20 per unit is quoted, and as high as \$1.30 per unit has been paid for Indian ore.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

CALCULATING MACHINES FOR ENGINEERS

By R. M. FARMER

For many years adding or calculating machines have been used in the offices of mining or smelting companies for ordinary routine work. It has long been recognized that they offer far more dependable accuracy and speed than the fastest human calculator could give, but, until recently, these machines did not find favor among men responsible for the technical details of operation for the reason that they were not sufficiently flexible in scope to include all the intricate calculations which occur in the work of mining and metallurgical engineers. Technical men were on the alert for a machine that would meet their requirements, for they realized that mechanical accuracy and speed are to be preferred to the fastest calculator, with his human tendency for error, or to the most adept user of a slide-rule. When such a machine was finally perfected it met with almost instant approval, and has since shown remarkable saving in time and in the intangible but very real losses occasioned through some slight error made when the brain was tired or when a guess between the graduations of a slide-rule was a thirty-second of an inch out of the way.

The appliance which has thus met the demands of technical men is the 'Monroe calculating-adding machine.' First used as an experiment, it has now become part of the standard equipment of the engineers and operators of such concerns as the Utah Copper, Braden, Chino, Ray Con., Phelps-Dodge, American Smelting & Refining, St. Johns, Cerro de Pasco, and many others.

The uses for the Monroe machine are legion, as the machine adds, subtracts, multiplies, and divides, with positive action and without the disadvantage common to other similar devices and to the slide-rule of having to carry some governing factor in the operator's mind, such as proper placing of the decimal-point or the number of times a multiplier or divisor has been used.

The American Smelting & Refining Co. uses a Monroe at its

DIAGRAM SHOWING OPERATION OF MONROE CALCULATOR

Perth Amboy plant, among other purposes for keeping its stock-book of ore on the dump and for compiling its records of assay and laboratory results. In computing this class of figures, or in estimating ore-reserves at a mine, an appreciable amount of time is saved with a Monroe calculator, to say nothing of the assurance that the accuracy is positive. The following example illustrates this fact.

Problem: to determine the number of ounces per ton in a vein of ore:

Width, ft.	Assay, oz.	Foot-ounces
7	1.22	8.54
4	0.54	2.16
12	1.20	14.40
8	2.20	17.60
5.3	27.40	145.22
7	1.60	11.20
3.5	0.95	3.32
6	0.39	2.34

66		204.78
204.78		
66	= 3.1 oz. per ton	

This was computed on the Monroe in 37 seconds.

THE MONROE CALCULATOR

Every technical man knows the amount of time that is wasted in checking up long additions or in repeatedly going over calculations involving decimals carried to the sixth place. Such work is performed on the Monroe machine at remarkable speed. Take, for instance, a case in point:

Problem: to determine an arithmetical mean gross-value for three-quarters of a year:

	3rd quarter	2nd quarter	1st quarter	Total
Tons milled.....	523,871	642,683	541,093	1,707,647
Gross value	\$1.01	\$1.112	\$1.207	\$1.111

Method:

$$(523,871 \times 1.01) + (642,683 \times 1.112) + (541,093 \times 1.207) = \$1.111$$

$$1,707,647$$

The time taken on the Monroe calculator was 17 seconds.

It has been shown that the operating speed of a Monroe calculating machine is greatly less than that obtained by other methods, but that the chance for inaccuracy has been brought to an irreducible minimum as well. When a problem is worked, the answer appears at the top of the machine, while at its side is shown a mechanical check on this answer. In multiplication, for instance, the multiplicand remains on the key-board, the answer appears on the lower dial, while on the upper dial is shown the multiplier (Fig. 2). Thus, no doubt is left in the operator's mind as to the accuracy of his calculation.

Simplicity of operation is a feature of the Monroe. To add or to multiply, the crank is turned in one direction, to subtract or to divide, it is turned in the opposite direction. Anyone who can push a button and turn a crank can use the Monroe. It has been found that the average man, unfamiliar with the machine, can attain fair speed in one week. At the present time, the Monroe is being used in the work of mining and metallurgy for estimating ore-reserves, surveying problems, calculation of assay and laboratory results, office routine, structural engineering problems, and cost-accounting in the office and in the operating plant. It should be borne in mind that the calculating machine finds its greatest usefulness on involved problems, and in rushing through work in a limited amount of time. As one mining engineer remarked, "we had to do two weeks work in three days and the Monroe seemed to be the only way out." When you have calculations as long as your arm, and as intricate as a mine-model, it is well to bring mechanical accuracy to your assistance. When one has been working night after night to late hours, the brain is certain to tire. Then it is that the human tendency for error is most liable to crop out, but even in such times of rush and worry, the *Deus ex machina* is infallible. It is well to let him shoulder the petty details of figuring and checking, and to save your brain for constructive thinking.

The calculating-adding machine used by all of the aforementioned mining and smelting companies is made by the Monroe Calculating Machine Co., Woolworth building, New York. Any request for detailed information should be addressed directly to them.

COMMERCIAL PARAGRAPHS

The LINK-BELT Co. is distributing a 12-sheet calendar, printed in three colors, containing 12 sheets with a separate illustration on each page, approximately 16 by 25-in. size. The company will send a copy to any responsible concerns that will write for one.

The LEFAX CORPORATION has just printed, and is distributing to subscribers, catalogue sheets in Lefax loose-leaf form for the following firms: SKF Ball Bearing Co., Hartford, Connecticut, ball bearings, hangers, and fall-blocks; Electric Weighing Co., New York, automatic belt-conveyor scales; At-

lantic Terra Cotta Co., New York, fire-brick. Each of these sheets is punched and indexed for filing in the Lefax data-books.

The AMERICAN SMELTING & REFINING Co. has just issued the December number of its 'Safety Review,' this being devoted to what is appropriately called 'Our Service Flag.' It presents a complete list of all the employees of the A. S. & R. that have joined the colors, with mines, smelters, and other departments from which they have been drawn. The honor roll includes 1147 names. An interesting feature of the list is that the civil occupations of the men are also given. We note a goodly sprinkling of Lieutenants, corporals, and sergeants, and one captain, this distinction falling to a chemist, Taylor Belcher, from the Omaha plant. The bulletin very happily explains the publication of this list of soldiers in 'Safety Review' by saying, "We are at war as a safety measure, to make the world a safe place to live in and to save political freedom to all men."

COCHISE ROCK-HAMMER

The Cochise Machine Co. of Los Angeles, California, manufacturer of the 'Cochise Rock-Hammer,' will move to its new building in South Los Angeles during the month of January. A well-equipped modern plant has been built to take care of the increased demand for the Cochise products. The rock-hammer shown in the accompanying cut is a drill

THE COCHISE ROCK-HAMMER

for sinking, driving, block-holing, plugging, stoping, and raising. It is furnished with attachments so that it can be used either dry or wet. It is fitted with an automatic oiling device and automatic rotation of a design that has proved most successful. The quick and efficient Cochise valve-mechanism is used in this drill. It possesses an exceptionally quick movement, and enables the hammer to strike fast and hard blows. This valve cuts off early, which allows the air to expand in the cylinder, thus saving power. Both valve and chest are made of steel, hardened and ground, and practically indestructible. A bulletin on the subject of the Cochise rock-hammer will be furnished upon request.

EDITORIAL

"IT is a trite thing to say that we are not awake. We are awake. We know there is a war, but the thing is so big we do not comprehend it. We are asleep so far as recognizing the full significance of the figures is concerned—of understanding how gigantic the task is." So says Mr. Vanderlip. Every man that loves his country should daily put the question to himself whether he has grasped the magnitude of what is yet to be done to make the world safe and serene with the assurance of freedom to live worthily and in peace. He should ask himself whether he has done all that he might do to aid in riding the world of crushing imperialism. The conscience and purpose of a democracy are the expression of the sentiments and purposeful activities that predominate among the individuals composing it. Let every man write the query "Have I done my best?" and put it where he must see and answer it each day.

RECOGNITION of the importance of training young men as technologists has been made by the War Department. Apparently the new regulation is well conceived to protect the country against depletion of its force of engineers and chemists. All technical students are accorded the privilege of enlisting in the engineers' corps, and after enlistment they may present a certificate of standing in their studies properly attested by the officials of the college or training school, accompanied by a petition for leave of absence until graduation. This permission is conceded automatically under the ruling of the War Department when the certificate presented shows that the academic grade of the applicant is as high as the upper third of the average grade of all students in the same school for the past ten years. This order disposes of one vitally important question in a manner that must win the commendation of all citizens that have thought seriously upon the larger problems of our national need.

SILVER has risen above 90 cents. The quotation appears to be responding to the intimation that the governments of the United States and Great Britain have arranged to purchase 100,000,000 ounces of the current year's production with a view to stabilizing the price of the metal; but we are informed that the Government, without specifying any definite quantity, is to

authorize the Director of the Mint to buy all the silver that is offered. It is rumored that the price is to be fixed somewhere between 94 and 97 cents. China is an active buyer just now, shipments from San Francisco westward having been at the rate of five to six million ounces per month. Not more than one month's production—8,000,000 ounces—was available for the coinage needs of our own government and that of England, so that the rise to \$1.15 in September was not surprising and it might have continued even to \$1.25 if an artificial check had not been established. The miners of silver protested against this interference with their opportunity to obtain compensation for the low prices previously prevailing and expressed a keen desire that official hands might be kept off the market. We understand this point of view, but believe it to be short-sighted. The fixation of the price at a moderately high figure, double the lowest quotation of three years ago, is better for the mining industry than a hysterical market affording no assurance of steady profit. As we announced in a recent issue, credible gossip in financial circles arouses expectations of an international agreement for a bi-metallic monetary basis. Thus, and thus only, could the two metals be associated so as to bolster the credit requisite for the expanded volume of international finance. There was no doubt that France was favorably disposed toward bi-metalism, if Great Britain would follow suit. The indications now point toward an understanding on this subject among all the allied nations.

COPPER mining at the Calumet & Hecla is the subject of a short article appearing in this issue from the pen of an experienced journalist, Mr. Homer Guck. He tells the story of the great copper mine that has given fame to the Lake Superior mining region and incidentally refers to the accident of discovery, through the unearthing of a 'cache' or store of copper by an enterprising pig. Edwin J. Hulbert is given as authority for this tale. It does not conflict with the account given to the present writer by James D. Hague. In 1853, while surveying for a road, Hulbert had found detached pieces of copper-bearing conglomerate and in 1858 he discovered the so-called ancient pit, which may be the same as the hole in which the boarding-house pig prospected with his snout. Such evidences of the existence

of a copper lode did not lead at once to the discovery of ore in place, for this did not follow until August 1864, when Hulbert sank a prospect-hole on a tract of mineral land that he had selected for exploration, and struck the Calumet conglomerate. Fortunately the ore was so rich at the point of discovery as to encourage development. However, the first ore produced for market from the Calumet lode was mined at the bottom of the 'ancient' pit early in 1866. It yielded 12% of copper. Thus, while the pit contained a 'cache' of copper, mined elsewhere, it happened to have been dug at a spot immediately above the copper-bearing conglomerate, but not so deep as to expose ore in place. This recalls the story of Chicken Bill and the Chrysolite, at Leadville. Our readers will remember that H. A. W. Tabor bought a claim, called the Chrysolite, from a notorious prospector called Chicken Bill. This enterprising person had not waited for his shaft to reach the ore-bearing limestone, but had taken rich ore from the Little Pittsburg mine and had 'salted' the bottom of the shaft. Tabor was deceived and paid \$40,000 to Chicken Bill, who then began to brag about his trick to some of his friends, so that the news of it reached Tabor's clients before he himself reached Denver, whereupon they repudiated the deal and Tabor had to keep the claim. He sank the shaft deeper and struck wonderful ore—this time in place! The Chrysolite yielded \$1,500,000 in profit to Tabor and his associates before they sold it to a New York company for another \$1,500,000.

Mexican Conditions

Mexico is said to be emerging from political chaos, but her economic condition is deplorable. A recent traveler, competent to judge through long familiarity with the Spanish language and the ways of the country, informs us that no real progress in reconstruction is being made. The Mexicans assumed that they could apply the magic touch of a socialistic constitution and, presto! the resources of the mine and farm would leap into the mints and granaries. The little matters of capital and industry and discipline were quite overlooked. It was to be expected that the socialists would disdain the need of capital, since they blame most of the disappointments of man upon the capitalistic system, without in the least comprehending the true meaning of capital nor realizing the wrong construction that persistently has been put upon the teachings of Karl Marx by his avowed disciples. At all events the Mexican free-for-all non-capitalistic handicap is proving a dead failure, and the people are cooling down to a point where the governmental leaders can explain to them the need of help, even from the 'gringo.' Our correspondent remarks that the Mexicans are beginning to see that, "in asking for help it must be on the understanding that the management, and the control of funds and revenue, will be demanded and required." 'Mexico for the Mexicans' is an excellent slogan, but it has nothing whatever to do with the

peaceful and normal development of their natural resources by outside capital. If the Mexicans will set aside their impossible constitution of Querétaro, swing back to the bill of rights in the constitution given them in 1857 by their true patriot, Benito Juárez, eliminate the principles of monopolistic concessions, thereby at one stroke cutting off the main artery of graft that has brought them so much evil government, they may hope to see their country arise from her desolation. It is not the wish of the people of America that Mexico should be humiliated, nor that it should be over-run by our army and annexed. The fact that we were able, when sufficiently stirred by a genuine national peril, to put on the trappings of war and display a strength before which any small nation might well stand abashed, is proof enough of the national attitude of mind. We do not even hint at an invasion of Mexico, although we are now in warlike temper. Mexico knows that she is safe against attack from her big neighbor of the North, despite the inconsiderate statements that sometimes creep into the daily press. We regret, for example, the intemperance of certain reporters who recently have made 'copy' out of ridiculous imputations to Governor Cantu of Lower California of a wish to offer his 'principality' to this country. Such nonsense, written by boys who are more smart than learned, and who know nothing of the history of Mexico and of the special fervor of her patriotic sentiment, utterly misrepresents both countries. Governor Cantu is a man of unusual intellectual gifts, a thoroughly progressive man, and so well disposed toward America that he is offering to supply us certain raw materials that we need; but he is also a Mexican, and the last thing a Mexican would do is to relinquish so much as a rock or a sand-spit of the Patria to a foreign power, save under compulsion of arms. Whatever family quarrels Governor Cantu may have with his political associates he is no traitor to his country, and the American people would despise him if he were. Mexico needs our kindly assistance at this moment, and we believe that she will look to us for the sort we can best render as soon as Argentina shall have cast to the winds the fiery anti-American doctrines of Manuel Ugarte and have aligned herself with the powers contending against Kaiserdom. Mexico needs, not only capital, but a close association with our banking system to re-introduce the machinery of credits, without which industrial recuperation is impossible. Just now the authorities have adopted make-shift means for obtaining a considerable amount of American gold coin through their customs and tax departments, and are endeavoring to re-coin it as fast as it can be delivered to the mint in Mexico City. This resource, however, is relatively small, since the exportation of gold from this country is permissible now only upon special executive order, and that is not conceded unless the circumstances render it peculiarly necessary. Practically, Mexico is dependent upon the gold produced from her own mines, and upon a return of 25% of exported silver in a gold equivalent.

and that equivalent amount constitutes the larger part of what is obtainable under export licenses, to which is added the quantity required to save American investments on which payment of taxes in gold is obligatory, which amounts to a little over \$10,000,000 per month. If not paid, and in gold, the property is, by decree of Carranza, subject to forfeiture to his Government. In order to stabilize Mexican currency the fiat paper has been retired, but the basis for bank-credits in proper proportion for a large expansion of industry is lacking. The banks are endeavoring to liquidate their outstanding circulation as rapidly as they can, and some are buying up their bills at a given rate in the open market, while others remain dormant, anticipating better conditions. We are finding that conscription of capital is impossible, and Mexico has found that its twin sister, confiscation of capital, is impossible. Such drastic actions result in extinction of the country's resourcefulness. It is in the encouragement of industry, and in the creation of confidence whereby the resources may multiply their usefulness as bases for credit, that the real ends of national development are subserved. The interests of Mexico and the United States are inter-related because of proximity and because of the complementary nature of the resources of each country. For purposes of finance no wide division can be drawn between them without mutual harm. As friends and allies we can be of assistance to each other, and our financial support will ensure the growth of a free and prosperous Mexico. The questions of reform have nothing to do with the gringo; these depend on the wisdom of the Mexicans themselves.

Geology at Jerome

Truth is stranger than fiction and facts are more romantic than fables. In this issue we conclude the story of the U. V. X. bonanza, telling how the wonderful orebody of the United Verde Extension mine, at Jerome, Arizona, was found by Mr. James S. Douglas. The thoughtful reader will not have overlooked the strange coincidence whereby James Douglas, the elder, missed getting hold of the United Verde, which William A. Clark acquired, to his great enrichment, and how Mr. Clark missed the riches in the United Verde Extension, so that it was left for James Douglas, the younger, to unlock that treasure-vault. "The whirligig of time brings in his revenges." We may remark, however, that both Dr. James Douglas and Senator Clark, as they are now known, were so successful in their mining operations elsewhere that the rejection of the United Verde by one of them and the missing of the United Verde Extension by the other have not proved disappointments of a tragic kind. Still we rejoice that the final achievement was left to the younger man and to his friends, so that the wealth of Arizona has found wider distribution. If there must be a moral to the story it is that the miner should not disdain the aid of the geologist. Senator Clark in vulgar phrase 'had no use for' geologists. That is accountable in part

by his unpleasant experience with Mr. George W. Tower, of the U. S. Geological Survey, at Butte; for that geologist had access to the Clark mines in his official capacity, and when he resigned from the Survey he used his information as an expert witness in the local mining litigation, which at one time had many of the characteristics of a vendetta. That may excuse the Senator's strong prejudice during recent years, but not his earlier inhospitality to geologists, whether official or unofficial. The late S. F. Emmons, a man to whom the Tower episode, made known in 1903, seemed a blow at the honor of the Survey, being himself most scrupulous in his use of information obtained as an officer of the Survey, records regretfully the fact that Mr. Clark's policy of excluding visitors, especially geologists, from the United Verde, prevented him from studying the evidence of secondary enrichment existing in that mine. That was in 1899. It is significant that when H. H. Rogers was organizing the Amalgamated Copper combination in 1898 he proposed to include the United Verde, but the negotiations broke down when Senator Clark refused to allow an examination to be made. So geologists were persistently excluded from the United Verde, and the Senator was so prejudiced against them that he did not employ one to guide him or his manager in the development of the mine. The consequence was that the combined effects of geologic faulting and secondary enrichment were not correctly apprehended, and it remained for a mining engineer from the outside to come into Jerome and uncover the bonanza under the noses of the people that had been exploiting the United Verde for 25 years. We do not insist that all the geologists made correct inferences; the story of the U. V. X. discloses the fact that several of them—and some pretty good men too—guessed wrong; but that is to be expected, seeing how young the science of ore deposits is and how uncertain are many of the criteria on which it is based. Still the U. V. X. remains a triumph of sound observation and scientific reasoning; it is far removed from the lucky accidents that started most of the great mines of the West, from the Comstock to the Camp Bird. The enterprise organized by Messrs. Douglas and Tener is also noteworthy as a clean promotion and a straightforward piece of business. It was conducted on a high level of integrity from start to finish; affording a good example to other incubators of mining adventure. It is not the fault of Messrs. Douglas and Tener if the U. V. X. has been used as an excuse for breeding a vociferous litter of wild-cats. The promoter of a puling prospect can point—and has not hesitated to do so—at the U. V. X. as a rich mine that was started on nothing, a successful development predicated on no superficial showing of ore; and, as one might expect, the so-called fiscal agents and other organizers of hair-brained schemes for collecting money from the public have used the U. V. X. story as an argument that can only be answered by those aware of the facts. The publication of the real story should serve to check a distortion of the truth, while at the same time offering encouragement to intel-

ligent exploration. The idea that there are 'one mine' districts—that a single mine may include within its boundaries all the rich ore in a given locality—is a notion that should be thrown aside. If it were given to the miner for an instant to have a radioactive vision enabling him to see into the crust of the earth, he would, we think, be astounded to see how much ore he had missed, even close to the workings he had made. Probably the undiscovered ore greatly exceeds that which has been mined, could we but see it, which is equivalent to saying, could we but find it without spending an excessive amount of money in the search. The geology of the Jerome district is yet to be deciphered. For that the microscope of the petrographer is necessary. Several experienced geologists have examined the district recently, and even the United Verde can now boast a competent guide in these matters, so we shall hope that fresh evidence will be produced, to the end that a clear and comprehensive explanation of the rock-structure may become available. The energetic prospectors along the line of the big fault need such help, and they ought to have it. Undoubtedly they would have had it long ago if the United Verde had not been closed to the U. S. Geological Survey; and now that the U. V. X. is open to official inspection the Director of the Survey should lose no time in delegating members of his staff to make an examination. Timeliness is essential to a geological report. Delicately worded obituaries and meticulous post-mortems are not in demand by those engaged in the operation of mines. It may be that Mr. Douglas's venture will furnish scientific evidence of great value, as well as much copper for making the munitions to be used in the achievement of victory on the battlefield. He undoubtedly is glad to have his copper put to military use, for he is a large-scale American whose heart is in the Great Cause—and more than his heart, for his son is in the U. S. Army, and he himself, leaving the accumulation of millions, is in France, serving the Red Cross with a bigness of spirit that is more than all the wealth of a copper mine, even of the one with which his name will remain forever linked in honorable fame.

Excess-Profit Tax

REPRODUCED BY PERMISSION

Referring to the incidence of this tax on mining, we have expressed doubt concerning the practicability and fairness of the Act passed by Congress on October 3. It is a pleasure, therefore, to record the fact that a committee representing the mining, oil, and gas industries was organized early in December under the auspices of the American Mining Congress to discuss the matter with the Advisory Board of the Bureau of Internal Revenue. The committee consisted of the following representative men: J. J. Shea (Oklahoma), A. G. Dickson (Pennsylvania), Herbert Pope (Illinois), Ravenel Macbeth (Idaho), A. G. Mackenzie (Utah), Emmet F. Boyle (Nevada), T. A. Dines (Colorado), A. Scott Thompson (Oklahoma), Victor Rakowsky (Missouri),

Paul Armitage (New York), Archibald Douglas (Arizona), and Albert Burch (California). After a conference with the Advisory Board, the committee was asked to formulate such an amendment to the present law as would be satisfactory to those engaged in mining. We do not repeat the reference to "oil and gas," because the exploitation of oil and gas deposits is 'mining,' and the distinction attempted to be made is a technical blunder. The amendment of Section 207, of Title 2, of the Act, was as follows: "That in the case of mines, oil and gas wells, the invested capital, at the option of the tax-payer, shall be (1) the average pre-war net income capitalized at 8%, and (2) paid in or earned surplus and undivided profits used or employed in the business since the pre-war period, exclusive of undivided profits earned during the taxable year; provided, that in the case of mines, oil and gas wells, having no pre-war net income, or acquired since the pre-war period, the 'invested capital,' at the option of the tax-payer, shall be (1) the net income for the year 1917 capitalized at 12%, and (2) paid in or earned surplus and undivided profits used or employed in the business subsequent to the year 1917, exclusive of undivided profits earned during the taxable year." This is not an amendment that can be approved, for it attempts to define while using terms that themselves need definition; moreover it will bear inequitably upon individual mines and is unlikely to meet the requirements of the Government. A later suggestion, made by Mr. Albert Burch, who was unable to be present at the conference, reads thus: "In the case of mines, oil and gas wells, the increase in the average price received at place of sale for each unit of product, that is, each ounce, pound, ton, barrel, or cubic foot, as the case may be, for the taxable year over the average price at which the same unit was or could have been sold at the same place during the pre-war period shall be ascertained, and 50% of such increase multiplied by the number of units produced and sold during the taxable year shall be deemed War Excess Profits and upon such War Excess Profits there shall be paid a tax in lieu of all other taxes imposed under this title at a graduated rate from 20 to 60%, varying with the percentage of increase in unit-value of product." Thus the factor of 'capital' is eliminated from the problem and those that have benefited most from the increment of prices due to the War are mulcted most heavily. The 50% of profit that is untaxed is supposed to be absorbed by the increased cost of production. There should be no difficulty in applying this definition, which, once and for all, escapes from the verbal morass in which the tax-gatherer and the taxpayer are floundering. Misconception as to the significance of capital invested in mining has led persistently to false reasoning in tax apportionment. Invested capital is fixed like the mine in which it is invested. It is the working capital that gives it the vigor to become productive. Working capital, however, is subject to wide variation, and is not a basis for equitable taxation, but it is logical to demand contributions from income, because that is the true measure of utility.

DISCUSSION

How to Ship Ore

The Editor:

Sir—There appears to be a dearth of knowledge at the mines concerning the condition of shipments of ore and mill-products and the kind of containers best suited to the needs of the sampler and consequently to the general satisfaction of both shipper and smelter. A good many shippers appear to think that the condition of the ore or concentrate or precipitate, as the case may be, is immaterial, so long as the stuff is loaded on the cars and sent on its way. I venture to make some suggestions that may appear superfluous to the initiated, but which to a surprising extent might be followed with resulting satisfaction to both shipper and smelter.

Starting with crude ore, the first requisite is uniformity of size, and the finer the better. Recently I noticed a shipment of silver ore from a Nevada prospect, the owner of which had installed a small crusher at the shaft; the ore was crushed to a maximum of one inch, sacked in good strong sacks, which were plainly marked, and loaded in four lots in a car, each sack bearing its lot-number. There was a feeling of satisfaction among the men in charge when this shipment was unloaded and sampled at the smelter.

About the same time another shipment was received from one of the oldest shippers on the Coast, supposed to contain three lots in a car. Some of the sacks had no mark on them, and nearly all were so rotten that it was impossible to carry them from the car. Of course, the best the man in charge could do was to make an approximate segregation of the lots after corresponding with the shipper. In this case two 12-in. boards would have made a perfect division of the three lots, and the sacks could have been dispensed with entirely.

In regard to marking sacks, where there are several lots in a shipment. One of the best methods is to tear up an old pair of overalls and tie a strip of the cloth to each sack. Another lot could be marked with pieces from an old red flannel shirt, and a third lot might be left with no marks. I have just seen the sampling of a shipment of concentrate that illustrates this point very nicely.

One of the large mining companies operating in Mexico shipped 578 sacks of concentrate on July 16, 856 sacks on July 23, and 670 sacks on August 6, each lot representing the output of the mill for a given period. Of course, these lots should have been kept separate in order that the mill superintendent could check the returns against his assays, but the steamer loading the lots at the Mexican

sea-port got them hopelessly mixed. On arriving at the smelter the only segregation that could be made was to take the number of sacks called for in each lot, as there were no distinctive marks. The first lot sampled was over a ton and a half short in weight and lacked some 1200 oz. silver in content, which fact elicited a prompt inquiry from the mining company. However, on checking the total weights of the three lots, there was nearly one and a half tons over the advised weights, and I have no doubt that the total value of the three lots will be satisfactory. Companies making regular shipments of concentrate from a distance, as in this case, should use linen tags on which the lot-number could be stamped.

Concentrate should be shipped in double sacks, or, in case of local shipment, preferably loose in the car, provided the car has a good floor. The car should be swept clean before loading and boards should be placed before the doors to prevent leakage.

Shipments of flotation concentrate are becoming increasingly important, and in this connection I want to point out a fact that merits consideration at the mine. I have noticed that some millmen, in their zeal to lower the freight-charges as much as possible, have dried the concentrate, apparently at a good deal of trouble and expense, to as low as 1% moisture. Believe me, that is dry. I saw such a lot of very high-grade flotation concentrate unloaded at one of the smelters recently. The stuff was loose in a box-car, and the wind was blowing, so in spite of all precautions in unloading, I believe there was a loss sufficient to pay a considerable part of the freight-bill. Then the lot had to be wetted before sampling, and as the metallic particles are coated with oil, it was almost impossible to accomplish the wetting, the result being a rather messy business all around. On the other hand, the moisture content should not be over 12%, but this is easily attained with the vacuum-filters in general use. I should say from my experience that the most satisfactory condition as to moisture for shipping and sampling is about 5 or 6%.

Regarding cyanide precipitate, the same suggestions as to moisture will apply, only with added emphasis. This product should not be dried completely nor should it be shipped wet. I have noticed recently several lots containing over 40% moisture. These lots must be dried carefully and screened before sampling. It is hard for the shipper to realize that his precipitate, worth probably \$40 per pound, has lost 40% in weight before being sampled.

I believe the best container for precipitate is the five-

gallon oil-can, with the carbide-can a close second. These are convenient and safe. Usually the handiest receptacle around a cyanide plant is the empty cyanide-can, but these cans filled with precipitate will weigh up to 350 lb., which is entirely too much weight for the cans or the cases enclosing them. In shipping this class of material it is advisable to mark the cases plainly, giving gross, tare, and net weights, so that the sampler or the shipper's representative may check the weights and notice any discrepancy at once.

Almost every mine in the country enjoys an individuality in regard to the shape and size of its bars, but as I have noticed an apparent desire on the part of the smelters to standardize to some extent the size of the silver bullion bars, I will give the approximate dimensions of the bar that appears to be the most satisfactory for the individual melting and sampling, as practised at custom smelters. A bar $4\frac{3}{4}$ by $16\frac{1}{2}$ in. long on the bottom, and $4\frac{3}{4}$ in. high will weigh about 2000 oz. This applies to the class of bullion produced at the silver mines of Nevada, Arizona, and Mexico. Each bar should be stamped with the mine number and weight. If there is matte on the bars it should be removed and shipped separately when enough has accumulated. The matte is easily ground and sampled as one lot of ore.

FRED G. TYRRELL.

San Francisco, December 21, 1917.

Mineral on Agricultural Land

The Editor:

Sir—Your editorial comment, in the issue of December 1, upon Leonard G. Blakemore's letter concerning 'Prospecting Conditions in California' is timely and interesting. I quite agree that retroactive regulations are contrary to our fundamental law, but, on the other hand, I question whether the miner will find any relief through the exception of minerals in any future agricultural patents, by reason of the fact that such has been already ineffectually tried. Thousands of U. S. patents to agricultural land have already been issued with clauses excepting the minerals, and yet no miner has been able to acquire title to the minerals contained in them. I refer not to the oil lands, which are frequently difficult of mineral determination but to the thousands of acres of mineral lands held by the Southern Pacific Co., and acquired by them as agricultural lands by means of sworn affidavits as to their iron-mineral character. Aside from the exception of minerals contained in these patents, I maintain that the title to the minerals in them has not and could not pass to the railroad company, for the reason that by an act of Congress, still in force, all mineral lands are reserved from purchase, sale, or grant, and can be acquired only under the mining laws, which require discovery, proper locating, assessment work, and the rest. In no other way can title to mineral lands be acquired, as provided by statute. Therefore, mineral lands held by any other shadow of a title are not legally held, and

are open to location and to perfection of title by any citizen of the United States. The Government should lend every possible aid to the discoverer of mineral and protect his rights to the acquiring of these minerals where wrongfully claimed under patents issued for agricultural lands.

Men are drafted, ships commandeered, steel and food prices regulated; why then should not the Government aid the miner in procuring title to mineral land when found on lands acquired through agricultural entry. If this class of land was patented as agricultural, and sworn affidavits were made as to its non-mineral character, why are so many portions of it being operated today for minerals under mineral leases issued by the Southern Pacific Co.? In order to protect innocent third parties who have already purchased some of these so-called agricultural lands from the Southern Pacific Co., why would it not be advisable for Congress to enact that, after a certain date the mineral portions of such so-called agricultural patented lands should be open to discovery, location, and mineral patents issued in compliance with law.

A Plea for Labor

The Editor:

Sir—The discussions and editorials on labor, in your issues of November 17 and December 8, should be read by all who have anything to do with the handling of men. I agree, in the main, with what both your correspondents, J. F. Harrington and 'A Miner' write, but consider there is a field for the contract system in every mine, if this privilege is not abused by those in charge of operations. What 'A Miner' says about the old worn-out men being consigned to the scrap-heap, is, in many cases, only too true, and I can quite realize how he feels about the contract and bonus systems. We are living in the age of the young man, and this applies especially to the Western States—an age when energy and the new science called 'efficiency' are the chief factors; an age of getting things done, without stopping to consider what the ultimate results of the methods employed may be. There should be a place, and a good one at that, in any mine, for men like 'A Miner'; or are those that have passed the prime of life no longer of any use? Young men for energy, and old men for judgment and counsel, and a proper blending of the two is good to keep the balance. "The glory of young men is their strength; and the beauty of old men is the gray head."

The cost-sheet, which is the whip over the back of the superintendent, only tells part of the story; perhaps the other part will remain untold until the great Book of Life is opened. We are laying too much stress on efficiency and the material side of things, and seem to forget that everyone has a right to a living, preferably in the occupation to which he has been trained, and if we are not careful, there is a danger of being caught and over-

whelmed by that wave of materialism which has gradually wrought such disaster to Germany as a nation—a nation that fills one with such dread and horror, that even education, which, during the last decade has been looked upon as a panacea for all evil, is now being questioned when one realizes what it has not done for Germany. "There is a reason", to use a phrase of one of our clever advertisers, why, in order to pass the local examinations of the great English universities, the candidate has to "satisfy the examiners in the rudiments of faith and religion." A sound knowledge of other subjects, minus this, is futile. Perhaps they realize that even such an excellent thing as education requires a good foundation in order to withstand the stress of time and storm.

When I was in New Zealand some years ago, most of the work in the mines, including the stoping, was done on contract, and I attribute the spread of this system, in preference to the wages system, to the scarcity of efficient shift-bosses. As Mr. Harrington points out, it was a case of getting contractors to do the supervision and the "driving". My experience of contracting has caused me to form the following conclusions: that the system has a tendency to eliminate the old and the unskilled men; to increase the wages of the workers; to decrease the cost of the work done. For such work as cross-cutting, shaft-sinking, and any work where valuable ore has not to be handled, I have always favored contracting; but for stoping and driving on ore one needs a better guide than the cost-sheet to find out whether it is an economical system. I have tried stoping by the ton and by the fathom, sometimes with wages-men to take care of the ore, but would far rather do this work with wages-men, who have the company's interest at heart, even if they are old men that are getting beyond the energy of youth.

The method of letting contracts is often much abused. A contract should be a contract, and binding on both sides. Prior to the establishment of the Arbitration Court in New Zealand, a mining contract was a somewhat one-sided document; it was usually a list of printed conditions with spaces left out for filling in the specifications of the particular piece of work being let. One of the conditions was that the company could stop a contract at any time without compensation to the contractor, the excuse for this clause being that the workings might become inaccessible owing to water or bad air. At a meeting of employers, held during a serious dispute between the companies and the miners, I called attention to the unfairness of this 'no compensation' clause, and as an illustration, quoted the ease of a party of contractors who had sent a long distance for their 'mates' and paid their traveling expenses, only to find that, after, about 10 days, the contract was stopped. When these 'Conditions of Contract' were investigated by the Arbitration Court, the Judge promptly objected to this particular clause, and it had to be eliminated. Another contract feature that the Court frowned upon was what is known as the 'monthly take' system, which applies to driving and stoping let by the month. The union representatives

were particularly bitter against this system, and, after hearing whole volumes of evidence, the Court knocked it out. The chief cause of complaint on the part of the men seemed to be that if they made good money one month they were cut down the next, and that the system gradually developed a species of 'soldiering'. At one large mine there was a system of letting large stoping contracts, usually taken by four to six men as contractors, these employing a sufficient number of wages-men to supply the required tonnage. These wages-men were paid more than the standard, as fixed by the Arbitration Court, but, notwithstanding their good pay, they developed dissatisfaction because the contractors, who, they claimed, were doing just the same work that they were, made more money. They termed it "blood money" and said the contractors were growing fat out of their labor. This proves that in some cases men will have just as much of a grievance against each other as against overbearing 'capital' as represented by a company.

There are, of course, many men who will shirk and not do a good day's work if they can avoid it, but I have always found that if one is fair it is possible to get good men, and with a combined system of wages and contracting there is a place for both the young and old. I do not agree with 'A Miner' that contracting, or even the bonus system, is necessarily 'killing' to the worker—nowadays we all have the 8-hour day, and I believe most men can stand 4 hours at a stretch, of even contract work, without harmful results, provided they have ventilation and other good working conditions.

Young and selfishly ambitious superintendents and bosses sometimes abuse the contract system, and it is in this direction that the more elderly officials of a company—the directors, for example—might give some supervision, using their judgment to curb the energy of youth. Any one who will read the story of Rehoboam and Jeroboam, as recounted in the 12th chapter of the first Book of Kings will realize that the counsel of young men sometimes lacks that wisdom which is essential to true success.

Flotation

The Editor:

Sir—I take pleasure in submitting to you some of the thoughts engendered in my mind by the perusal of your book on 'Flotation.' I have been interested more particularly, as you know, in the precise function of oils when chemical additions are made to the pulp, and in the reasons for the different grades of concentrates resulting from the use of various brands of oils.

Sulphuric acid may cause adsorption, say, of positive ions on the sulphide particles and consequently if the surface concentration of the ions is sufficiently large, that is to say, if the critical contact-area is exceeded, the sulphide particles will manifest an induced attraction for and a migratory tendency toward the negative bubble.

films, when the ions are firmly adsorbed. By 'critical' contact-area I mean that minimum area of contact between two substances, *A* and *B*, beyond which one substance *A* will impart to the other substance *B* its own polarity, that is, the polarity of *A*. This concept of the function of acid would explain directly the improvement in the grade of a concentrate, although I do not disregard its beneficial effect in wetting the gangue, affecting the degree of flocculation and the surface-tension, in cleaning the sulphide surfaces, and in altering the viscosity of the oiled films. Where acid is beneficial the use of lime may be detrimental by causing a different degree and kind of ion adsorption; both acid and alkali may have a good or ill effect by chemical inter-action with the pulp.

When different oils are used the important causes of varying recoveries may lie in the different viscosities of the bubble-films, and in the varying degrees of adhesion of the oil to the sulphide particles. These two factors seem to merit most attention, although electro-static charges may in some cases be not without their influence. The grade of concentrate may depend also on mechanical manipulation of the flotation machine. With too thin a bubble-layer, that is, too high a pulp-level, fine gangue-particles may be literally bombarded over the lip of the cell. The use of a large amount of air has a similar effect, especially if the froth is at all viscous, for the finest gangue-particles are projected into it and remain entangled there. The froth-cleaner cells should always have a thick blanket of froth, which is made to overflow gently, and the bubbles should preferably be somewhat brittle. This would give any granular gangue-particles time and opportunity to slide back into the pulp. With a higher heading-value a better concentrate is obtained because, for one thing, the froth being more uniform, the cells are so much the easier to control. Then, again, with a comparatively rich feed, if much air is not being used, and if we have an oil that does not yield a voluminous froth, the grade must be higher, for the sulphide particles being preferentially attached to and covering the bubble-film there is less exposed surface to which the finest gangue-particles in the pulp can adhere. It seems to follow that the amount of froth that should be produced is a function of the richness of the feed. I took some flotation-concentrate assaying 6% copper and re-floated one portion after adding sodium carbonate, and the other after adding sulphuric acid, obtaining two concentrates of practically the same grade. In this instance, therefore, alkalinity or acidity of the pulp had, per se, no different influence on the results. The electrolytes may be assumed to have modified the bubble-films in the same way.

Thinking that by baking the rougher-concentrate before re-floating I might produce a markedly cleaner concentrate, I tried the idea, but with no success. I should like to have an explanation of the following: Into a filtered solution (in an assay of copper by the cyanide method) I put a small drop of Barrett No. 4 oil and, at once adding the ammonia, shook the flask for a minute.

The solution seemed to be quite clear. On adding one cubic centimetre of the cyanide solution a faint opalescence appeared; this, with further addition, developed into a dirty-green very fine precipitate, which was filtered off and the titration finished. A second assay was run without an addition of oil; the results were:

With oil3.4 cc. KCN necessary
Without oil3.9 cc. KCN necessary

In the former instance, was the copper included by the emulsoid as cuprous ammonium hydrate?

When a complete analysis of flotation-concentrate is desired I should like to point out something that is often overlooked. The froth should be broken down and well-washed with distilled water, otherwise to the legitimate sample there will be added the soluble salts that are precipitated on evaporation of the solution. Where no precautions are taken the assay-value, for example, for the alumina content may be fictitious, especially in froths derived from an acid pulp.

Heap Leaching of Copper-Sulphide Ores

The Editor:

Sir—I have read with great interest the long and interesting article on the above subject in the MINING AND SCIENTIFIC PRESS for November 24. While agreeing with the article as a whole, I beg to submit herewith one or two corrections.

1. With regard to recovery, one is apt to read at the beginning of the article that 80% recovery has been demonstrated in actual work of eight months. If, as a result of the experimental work, the sentence, page 749, should read, "the entire process has demonstrated a 'probable' recovery of 80% of the copper in the ore," it would be clearer. Of course the sentence at the end of the first paragraph on page 757 may make it perfectly clear to the careful reader that the 80% recovery is expected in about two years.

2. While admitting the possible formation of metallic copper in the heap, one must always remember that an increase of the same agent, $\text{Fe}_2(\text{SO}_4)_3$, that helped to produce the copper will also dissolve it, see the equations 5, 6, and 8, page 755, and so this possible evil "dies aborning."

JOSEPH IRVING.

Bisbee, Arizona, December 12, 1917.

THE first unit of the cyanamid plant for the fixation of atmospheric nitrogen is nearing completion at Sheffield, Alabama. The plant is being erected as a result of close co-operation between the Ordnance Bureau of the War Department and the American Cyanamid Co., as a war-emergency measure. The plant is to be operated by the commercial organization, but is probably being financed by the United States government. It will be the largest works of the kind in the world.—'Oil Paint & Drug Reporter.'

The Story of the U. V. X. Bonanza—II

By T. A. RICKARD

Now comes the question, how much of this was mere luck and how much of it was due to inductive reasoning from good evidence? When one hears of a great mineral discovery one naturally asks whether luck or science was chiefly responsible. If it was luck, nothing much is to be learned; if science, then the evidence in the case may prove useful to other explorers. In order to obtain an answer to this question, I made a study—such as a

metamorphism the schist became partly crystalline and by shearing the diorite became schistose, so that today it is difficult to distinguish between them. The formation may be called a diorite-schist. Into this rock there penetrated copper-bearing solutions, forming lenses of copper-pyrite at the contact of the schist and diorite. Thus the original copper ore was of pre-Paleozoic origin. Geologically the U. V. X. mineralization is of remarkable

CROSS-SECTION OF THE JEROME DISTRICT. THE IRRUPTIVE ROCKS ARE INDICATED WITHOUT ATTEMPT AT PRECISION

journalist-engineer could make in two or three days—of the mine and its geologic environs. In making this inquiry I was aided by Mr. Douglas, to whose hospitality, mental and physical, I am greatly indebted.

The geologic structure of the Verde district may be outlined as follows: The basal rock is a schist, correlated with the Yavapai formation of the Bradshaw quadrangle. This schist is geologically ancient, probably of pre-Cambrian age. It is composed of metamorphosed volcanic tuffs and flows, together with clastic sediments, which in the Jerome district are both argillaceous and siliceous. Into these consolidated oceanic sediments a batholith, or mass of intrusive igneous rock, was pushed. The batholith was granite; from it tongues and dikes penetrated the sediments, which, by metamorphism, became schist. The marginal phase of the granite was diorite; this intruded into the schist so freely as to constitute a large proportion of its bulk. By

antiquity. On the basement complex, after it had been eroded by weathering, there was deposited, in late Cambrian time, the sediment that now appears as beds of sandstone, and later still, probably in the Carboniferous period, a greater thickness of limestone. This series of rocks underwent the movements incidental to the adjustment of the earth's crust to its cooling and shrinking interior. Breaks were followed by intrusions of magma from underneath, forming more dikes and tongues of igneous rock. The substance of these was the felsite* and quartz-porphphyry now exposed at the surface or underground. Where these dikes cut through the ore-bodies they have been kaolinized and bleached, and are known locally as 'watercourses.' Erosion modified the surface successively between these periods of sedimentation and vulcanism. Upon the series of unaltered sedi-

*This may be andesite; I use 'felsite' provisionally.

ments that covered the earlier complex there overflowed, in Tertiary time, from a volcanic vent, a lava of the kind known in Arizona as 'malapai,' a word derived from the Spanish *mal pais*, meaning 'bad land.' This is a rock of the basalt type.

On referring to the U. S. Geological Survey's folio on the Bradshaw Mountains, published in 1905 and devoted to a preliminary description of the region, I find that the authors, T. A. Jagger and Charles Palache, state that diorite "forms the west wall of the United Verde ore-body." This diorite they describe as "a basic border phase of the Bradshaw granite and is found chiefly on the borders of large masses of that rock along its contact with the Yavapai schist," where the granite has intruded into the schist. The sandstone and limestone at Jerome are said to be "outliers of the great mass of horizontal Paleozoic and Mesozoic sediments that form the high-plateau region of northern Arizona and New Mexico."

The ore was precipitated from solutions following in the wake of deep-seated intrusives. Copper was deposited in fractures and in the crushed rock adjoining fractures or between them, and by substitution of the more soluble portion of the schist formation. The earlier mineralization was associated with the intrusion of the diorite, before the deposition of the sandstone and limestone. The main fact is that the ore is in the schist near the contact with the older intruding igneous rocks, but equally important is the belief, so fully confirmed by evidence as to have the value of a fact, that the rich ore-bodies of the United Verde and U. V. X. mines do not represent the mineral as deposited primarily, but they are enrichments of the original copper mineral through the addition of the copper brought down by percolation from above.* The primary mineral is chalcopyrite, the secondary is chalcocite. As the surface of the copper-bearing schist was weathered and eroded, the copper was dissolved by the ground-water and carried downward, to be re-precipitated as chalcocite, which covered and eventually replaced the chalcopyrite. This process of migration and concentration was not confined to a short space of time nor to a single geologic period; it began soon after the primary ore was deposited, but the product now removed by the miner is the result of actions and reactions that have been at work from remote ages until today.

It will be understood therefore that as this ore was formed in the diorite-schist, under the thick covering of younger rocks, there would have been no evidence available to the miner if these overlying rocks had not been removed by erosion, so as to expose the deep-seated ore-

bearing formation. This exposure was brought about by faulting. See Fig. 4.

In the U. V. X. mine, as we have seen, the schist and diorite are covered by 500 ft. of sandstone and limestone, and these in turn by a cap, 200 ft. thick, of lava. No sign of the rich orebodies exists at surface. Walking up the steep hillside the miner finds that the basaltic lava, or 'malapai,' ends abruptly; above a line, or band, of crushed rock running athwart the slope there appears the schist that contains the rich orebodies of the United Verde mine. Higher on the hillside there is a succession of sandstone, limestone, and lava—like the section exposed by the U. V. X. workings. The break between the upper and lower series, where the recent lava is now in contact with the old schist, marks the course of a fault. The town of Jerome is distributed along this fault, because the scarp of it furnished footing for buildings. For two miles the course of this fault is N 37°W, for five miles it is N 53°W, but the strike varies widely, between due north and N 60°W. It is a corrugated surface, not a simple plane of movement. The dip of it is about 65° north-eastward near the Daisy shaft. It runs south-eastward from below the United Verde slag-dump, under the town, underneath the post-office, passing close to Miller's store, above the lower school-house, and nearly under the two upper school-houses; thence it drops into Deception gulch, where the shaft of the Calumet & Jerome mine is almost in it, but just above it. The vertical displacement produced by this dislocation of the earth's surface is 1700 ft. and the horizontal displacement is 900 ft. down-hill, that is, north-eastward. If restored to its former position the main orebody in the U. V. X. would be underneath the post-office of Jerome. Now it will be evident why the U. V. X. orebodies remained so long undiscovered. There was no sign of them at surface, there was no proof of a continuity of the United Verde orebodies into outside ground, and Senator Clark took pains to prevent others from obtaining any such information as would have encouraged systematic search.

On May 21, 1917, Mr. Douglas took me underground in the U. V. X. mine. In the 800-ft. station of the Edith shaft the sandstone appears, but 300 ft. southward and 200 ft. westward the drifts penetrate diorite. This rock has a schistose structure and is not easy to distinguish from the true schist, which has been so metamorphosed as to resemble a diorite. Together these two rocks constitute the country-rock of the ore-zone. The principal orebodies appear to be adjacent to, and replacing, a series of later dikes, now much kaolinized and devitrified into felsite. Mineralization is intensive where this felsite traverses the contact of quartz-porphry and diorite on the north side of the ore-zone; in short, the ore is found in a complex of eruptives the true relations of which can be determined only by aid of close microscopic study. I

*S. F. Emmons, in 'The Secondary Enrichment of Ore Deposits,' Vol. XXX, p. 192, Trans. A. I. M. E., speaking of the United Verde mine, said: "The physical conditions there more nearly resemble those of Butte than at either of the other localities [Bisbee, Globe, and Clifton-Morenci], and an underground study would probably have been most instructive. Unfortunately, the policy of the exclusion of visitors pursued by the owner was strictly enforced in my case, and I could only determine that rich sulphides do occur beneath the gossan."

†It must be remembered that the depth of the levels is taken from the old Daisy shaft, the collar of which is 154 ft. higher than that of the Edith shaft.

am informed by Horace V. Winchell that much of the supposed quartz-porphyry is only quartz. Mr. Winchell makes the illuminating suggestion that the jasperoid quartz covering the orebodies and common elsewhere in the pre-Cambrian rocks is not a 'cap' nor a leached gossan, but a part of the original country-rock, in this respect resembling the jasper of the Keewatin series in the Lake Superior district. This quartz, he believes is not veinstone but a siliceous oceanic precipitate produced in pre-Paleozoic time.

The conditions at Jerome are by no means unusual; on the contrary, our experience of mining all goes to

bodies is S 70° E in a mineralized zone about 1000 ft. wide. The ore within this zone follows no uniform direction, the strike and the shape being irregular, as modified by a network of fractures and dikes. The big fault has not been cut near the main orebody; it ought to be about 170 ft. south-west of it; it is probably steeper than generally supposed. As seen in the Daisy workings the fault appears as a confused mass—40 to 100 ft. thick—of crushed rock, consisting of mud and fragments, torn from the strata through which it has passed.

The main orebody is bounded on the east and south by a kaolinized selvage; this shows native copper in leaf

show that there is no more favorable place for the deposition of ore than where schist has been fractured and penetrated by eruptives followed by thermal waters. Rio Tinto is an old example; Miami is a later one. This fact has been linked, in hypothesis, with the big fault, but it is important to note that the fault cuts the basalt and therefore is post-Tertiary.† A tunnel on the Hermit claim, I am informed, cuts the fault and exposes the relationship just cited. Along the system of fractures the mineralizing solutions were enabled to circulate and deposit their content of copper. The trend of the U. V. X. ore-

form near the smaller orebody at 1407. East of the main orebody the kaolinized rock includes several inches of chalcocite and on the west this vein of chalcocite separates the 'felsite' from 'quartz-porphyry.' Only microscopic investigation can furnish data for a correct labeling of these rocks.

If one may be permitted to theorize on such slender evidence, I would say that the youngest kaolinized dike-rock was the chief agent in producing the concentration of copper mineral that we call 'rich' ore. The diorite is ore-bearing where crossed by this 'felsite,' particularly where the 'quartz-porphyry' contacts provided facilities for fracture. Such fracturing was intensified near the line of the big fault. Thus conditions favorable to ore-deposition were localized. The diorite-schist is pene-

†Although the fault may cross the basalt, it is possible that this is merely an extension, due to renewal of movement in Tertiary time, of a rupture caused and a line of fracture established at a much earlier geologic period.

trated by veins of quartz and iron-stained shear-lines. Along some of these copper is to be seen in oxidized condition, as carbonate. That brings me to the evidence that induced Mr. Douglas to spend a large sum of money in search for ore.

Mr. Douglas was attracted, in the first place, by the iron-stained vesicular ('vuggy') quartz at the south end of the Fisher drift, on the hanging-wall side of the fault in the Daisy workings. Similar signs of ore were noticed by him in the north-easterly cross-cut, which for 270 ft. runs through decomposed iron-stained schist showing coppery stains along the planes of schistosity. Again, he was impressed by the patch of chalcocite ore cut in a raise at a point 100 ft. above the 800-ft. level. This also lay on the hanging-wall side of the fault, that is, on the side where he expected to prospect. The ore had been dug out, so that none of it was to be seen in place, but some of it remained on the dump, and he believed the statement concerning it to be true. He had a good general idea of the local geology and of the structural conditions produced by the fault.

As I stood on the ridge between Mr. Douglas's house and the Edith shaft, I looked up the ugly hillside toward the United Verde mine and asked myself whether, having seen the evidence described to me by Mr. Douglas, I would have been inclined to spend my own money and my friends' in a costly search for a bonanza. Frankly, I have too little of the speculative temperament to have started the project in the big way in which Mr. Douglas carried it through, but if I had been engaged to advise a rich man in the matter, I would have told him to go ahead. Let me describe what an observant miner sees from the spot I have indicated: On the crest of the hill due west, above the Daisy shaft and behind the United Verde buildings, the level line of the white limestone makes an escarpment. The sandstone appears under the limestone, as can be ascertained by closer inspection. Just above the United Verde shaft-house one sees a big open-cut, or 'glory-hole,' in the diorite-schist underneath the sedimentary rocks. The slag-dump cuts across the hollow in which Bitter creek has its source. The fault is suggested by the break between the diorite-schist and the near ridge of malapai. Even an amateur geologist can follow the line of crushed rock marking the fault, which runs through a gap between the malapai ridge of Main Top hill and the higher slope on which the United Verde slag-dump rests. The fault crosses the hillside just above the Daisy shaft and under the stable on the left, south-eastward toward the town of Jerome. The bed of Bitter creek is a gully full of the detritus of the rocks above, washed from the outcrop of the fault. The malapai in front and to the right on Main Top hill has been eroded to a thin edge on the near or eastern slope, exposing the limestone underneath. Below the limestone the sandstone appears, and following the slope toward the Verde valley a series of horizontal limestone beds is uncovered, suggesting block-faulting.

The relation of the beds of limestone and sandstone near-by to that of the similar series on the top of the hill,

with a pronounced line of crushing and movement between, is a plain indication of a fault. Above the fault there had been found copper ore of extraordinary richness and in large masses; why then should not similar ore be found on the lower or hanging-wall side of this fault? That seems an obvious question. Fisher answered it affirmatively and proved the courage of his conviction by starting to prospect in the Little Daisy ground. When Douglas took hold of the venture he could see what Fisher had seen on the surface, he understood the effect of the fault in dropping the ore-bearing zone, and he had the further evidence furnished by the patch of chalcocite that Fisher had found in the Daisy workings. Small as it was, it sufficed to prove that the ore-making or copper-concentrating process had been at work below the fault. This evidence of secondary enrichment was highly important. Moreover the fault had been cut in the Verde adit* (called the Hopewell tunnel). It seems to me that on that evidence a group of rich men could afford to risk \$225,000 in searching for ore. The ante was not too big for the game.

I have not included the oxidized copper among the favorable signs. It had no immediate bearing on the problem. Such copper stains and patches of carbonate ore were mere *humo de cobre*, as Mr. Douglas, out of his familiarity with mining on the Mexican border, calls them. They were quite different from the *hilos de calcocita*, or threads of chalcocite, that indicate secondary enrichment. Such oxidized copper has been precipitated probably from the water draining down-hill from the outcrop on the United Verde ground, coming down Bitter creek and seeping into the lower ground. On the other hand, the silicified rock poor in copper, but still stained by it, might represent the upper portion of an orebody the copper from which has been leached for the benefit of the bonanzas in the deeper zone. It is probable, however, that such a conventional explanation would be wrong. The copper stains are exogenous not endogenous, as Posepny would have phrased it; they came from outside and are not remnants of copper the rest of which has been removed by leaching. It is likely that seepage from above explains the presence of the precious metals in the copper ore. In the Copper Chief mine, on the outskirts of the Jerome district, an enrichment with gold and silver is traceable to the overlying limestone. It is probable, as Mr. Winchell suggested to me, that carbonated waters from the limestone brought gold and silver into the gossan formed by the weathering of the masses of copper ore in the United Verde, but not in the U. V. X. mine, since the latter was enriched for the most part in pre-Cambrian time, before the limestone was laid down.

The bonanzas are now three or four hundred feet below the former surface of the schist. They were formed by the enrichment and alteration of the quartz, pyrite, and chalcopyrite of the primary ore. Where oxidized they show residual limonite and appear like the vesicular copper-stained quartz on the 800-ft. level of the Daisy

*Through which the ore of the United Verde passes on its way to the smelter at Clarkdale in the Verde valley.

workings. The erosion of the fault-escarpment, containing broken fragments of ore, would cause copper to be dissolved in the water of Bitter creek. On the upper side of the fault a large tract of Cambrian land-surface has been eroded, removing part of the ore-zone, and some of the copper that was in it may have been washed downward to enrich the other and intact part of the ore-zone that was preserved under the sedimentaries and under the cap of lava. Whether mineralizing solutions from the schist followed fractures into the overlying limestone, and there formed orebodies by replacement, is a nice question. Some of the ore found, for example in the Dundee & Arizona mine, may be of this character, but as

orebody must have occupied a position underneath the post-office in Jerome, and the main orebody must have lain still farther from the United Verde. The orebodies in the two mines are not projections of each other; they are connected not on the dip but on the strike of the ore-channel, which does not coincide with the fault. There was a connection of mineralized ground along the strike in this ore-channel, and it was disrupted diagonally by the fault. The fault itself dips more flatly than the ore-channel and they should intersect in the U. V. X. ground at a depth of about 2000 ft. That disposes of the possibility of apex litigation.

The heavily sulphurous character of the ore presents

THE U. V. X. SHAFTS, LOOKING EASTWARD, SHOWING THE EDGE OF THE DARK COVERING OF BASALT ON THE WHITE LIMESTONE

to that I do not know. When copper has been found, whether as carbonate or sulphide, in a given spot, it is not possible off-hand to say whether it was precipitated by ascending or descending waters, but the answer to such a question can be made after careful investigation, and it furnishes information of immediately practical value to the prospector. In the United Verde both chalcocopyrite and bornite are found down to 1800 ft., that is, far below the chalcocite zone of secondary enrichment, which has yielded bonanza stopes for a vertical depth of 800 feet.

Next comes the question of the connection between the United Verde and the U. V. X. orebodies. In the first place, the latter is not a part of the former, that is, if the ground were restored to its former position, as it was before the faulting, the U. V. X. orebodies would not connect with those of the United Verde. Originally the U. V. X. ore was higher than that of the United Verde. Before the ground was faulted the smaller (or 1407)

a danger against which the management of the U. V. X. mine must guard systematically. A forcible reminder exists already. In approaching the 1407 stopes, in the smaller orebody first discovered, the temperature rises rapidly to 103° F. Farther it is not safe to go, the heat and gas being dangerous. Iron wire, broken car-wheels, and other scrap have been thrown into the ditch alongside the track, so that the water issuing from the burning ore may precipitate its copper. After passing over this scrap-iron the water is neutralized by the addition of lime carbonate so as to destroy the acidity, which otherwise would corrode the pump-line. Combustion has been started by caving. The stope was carried five sets above the level, the ground being held by square sets filled with waste, except at the working end, which was two sets wide and two sets high, not filled. A round of holes was shot in ore at 11.30 one morning and indications of caving were visible when the men returned to work after the noon interval. The men were withdrawn immediately

and at 3 p.m. the whole east side and the back of the stope collapsed, crushing the timbers all the way down to the sill-floor, the height of five sets, or 41 ft. The rise in temperature became sensible in a few days. The cave started four sets above the 1300-ft. level and dropped the ground 8 ft. This was enough to develop sufficient friction to cause combustion in an ore containing 28% sulphur, according to reactions utilized in converting matte where there is iron sulphide that is readily oxidizable in association with copper sulphide. The misfortune was hastened by the fact that the rich copper ore dipped at an angle of 60° and had an overburden of crumbly pyrite. The block of ground 'on fire,' that is, in a state of smothered combustion, contains 2000 tons of 30% ore.

The neighboring United Verde mine has suffered severely from this cause. The first fire, in 1894, was due, as in the case just cited, to spontaneous combustion following a cave. As it could not be extinguished, the place first affected was bulkheaded so as to prevent a spreading of the fire, but even this was not done completely, therefore "the smoke and gas worked its way over the orebody on the different levels and cut off a large productive area of high-grade ore," as Robert E. Tally, the superintendent has related.⁹ Two other fires started, doing great injury to the mine. An attempt was made to extinguish the combustion by flooding with water, but this failed, the air inevitably finding its way to the burning ore. Then carbon di-oxide gas and steam were tried, in turn, but in vain. It was found impossible to shut off the parts affected so as to apply these remedies effectively. In 1905 the plenum system was introduced. This consists in forcing air against the gas generated by the combustion; an air-pressure of 2 to 5 lb. suffices to keep back the gas and cool the ground sufficiently to render mining possible. Mr. Tally states that by this method the temperature was reduced from 1200° F. to 120° F. in about six weeks. Gradually, by ventilation, the temperature was lowered to 75°. The air forced into the hot stopes now finds an outlet through raises in the foot-wall direct to the surface, so that the gas does not penetrate the upper workings. The current of air is regulated by doors connecting with the stopes at successive levels.

To extinguish a mine-fire is satisfactory; but to prevent one from starting is better. The mass of low-grade pyrite on the hanging-wall side of the rich ore at 1407 was so loose as to run like sand; it was separated from the chalcocite by two feet of soft decomposed rock, so that the conditions were peculiarly treacherous. Exactly similar conditions may not be repeated elsewhere in the mine, but something like them has to be faced in other parts. The ore-ground is exceedingly 'heavy,' in the miner's sense, as it is also in terms of specific gravity. Seven cubic feet of ore weighs a ton. The chalcocite breaks in slabs; it is brittle; it breaks readily; in stopping, a few 'pop shots' suffice. To prevent 'runs,' the ore has to be bulkheaded continually.

Mr. Douglas and Mr. Kingdon are fully alive to the perils of fire in ore of this character. To safeguard the mine it is proposed to make barriers across the big orebody. A cut 12½ ft. wide will be carried through the ore; this will then be filled with waste from the surface. Any waste used for filling should contain less than 3% of sulphur. Thus a fire-proof barrier will be formed. Other barriers will follow at 25-ft. intervals. The cost of any such protective method is unimportant in such rich ore as compared with safety and completeness of extraction. The ore is so rich that it must be removed cleanly.

Good ventilation is another prime requisite; therefore the Daisy shaft is used as an upcast, so that fresh air comes down the two working-shafts. The new, or Concrete, shaft is 250 ft. east of the Edith; it was sunk only 170 ft., the rest being done by raising from the different levels. An ore-pocket to hold 1000 tons of each of the two classes of ore is to be made between the 1100 and 1300-ft. levels; this pocket will discharge into 30-ton cars driven by an electric-storage motor through an adit, 11,200 ft. long, which enters on the 1300-ft. level. The mouth of the adit is 4¼ miles from the smelter, to which the ore will be delivered on a 1.7% grade and 4° curves. The smelter, designed by A. G. McGregor, will have a capacity of 1000 tons of ore and is to be finished in 1918. Then the U. V. X. mine will be equipped for steady production.

Manganese in Arkansas

The high prices for manganese ores have stimulated interest in the little-exploited manganese deposits of west-central Arkansas. These deposits are found at intervals in a belt 4 to 12 miles wide, which extends west-southwest from Pulaski county, at the centre of the State, to Polk county, on its western border. The deposits have been worked only in a small way and have produced but a few hundred tons of marketed ore. The ores consist of the four oxides, psilomelane, pyrolusite, manganite, and wad, the first three forming the larger part of the ores. Although these minerals may be found separately, two or more are generally intimately mixed in the same deposit, and at some places they are associated with iron oxides and manganiferous iron ores. The manganese ores occur as nodules, pockets, and short irregular veins from a fraction of an inch to 4 ft. thick, though veins 4 ft. thick are rare. The orebodies are scattered through the hard Arkansas novaculite and can doubtless be found on every mountain where the novaculite is exposed. They occupy bedding planes or joint cracks, or form a cement in a novaculite breccia in which the rock fragments range in diameter from a fraction of an inch to over a foot. Most of the ores contain too much phosphorus for use in the manufacture of ferro-manganese, and too much iron for use in chemical industries and electric batteries, and where the quality is suitable for these purposes the quantity is generally too small for profitable mining.

Hoisting-Ropes

By M. H. SIGAFOOS

*Until recent years it was generally conceded that the foreign steels for the manufacture of wire-rope were by far the best, due principally to the fact that Swedish ores, considered the finest the world affords, are employed as their basic foundation. Such foreign steel as is imported by the American manufacturer for wire-rope purposes, is made to meet rigid specifications, insuring as nearly as possible a uniform quality, and is carefully tested and analyzed to insure correct percentages of manganese, silicon, and carbon, as well as the great necessity of their being extremely low in sulphur and phosphorus. Both of the latter elements are detrimental to the production of wire to be used in the manufacture of wire-ropes. Acid open-hearth steels are admitted to be better than basic open-hearth and it has been suggested that this is due to the higher oxygen content in the basic steel. Much has been claimed for the qualities of chemically treated steels, such as vanadium, chromium, and others, and in many instances they have proved the claims made for them, but for use in wire-rope they are still in the experimental stages, and no data are available at this time.

Wire made from steels intended for the manufacture of wire-rope for ordinary purposes is divided into three classes, namely: Iron, with a breaking-strain of approximately 80,000 lb. per sq. in.; cast-steel, often erroneously called crucible-cast, which has a breaking-strain of 170,000 to 180,000 lb. per sq. in.; and plough-steel, with a breaking-strain of 200,000 to 250,000 lb. per sq. in. Wire is often drawn to a considerably higher tonnage, but this is rarely used for any other purpose than for standing-rigging on racing-yachts, where maximum strength, with the lightest possible weight, is essential, such wires are sometimes drawn to 260,000 lb. per sq. in. Very small sizes of wire-rope or strands for aero-plane-guys are drawn to even a higher tonnage.

There has been much discussion on the point as to when a wire-rope has reached the end of its usefulness, and when it should be removed. Up to the present time it seems the question remains unanswered.

After an exhaustive investigation of the bending and load-stress, conducted by the Bureau of Standards, a report was published, as Bulletin No. 75, stating in substance, that a rope should be removed after a certain number of broken wires appear in each of the strands. The tables in the report undoubtedly have been compiled from stated loads, speeds, head-sheaves, and drum-diameters; from shafts of various depths, and, taking into consideration the torsional and load-stresses, they

form a useful guide. However, as there is no standard of sheave and drum-diameters, except those recommended by rope manufacturers, nor any set rule for maximum loads, it is evident that with each variation in the diameter of sheaves or load, so will the bending-stress and the load-stress vary. Both of these stresses are of great importance and have a direct bearing on the factor of safety. In the catalogues of the wire-rope manufacturers are to be found the 'proper working-loads' of wire-ropes for the given sizes and grades. This, in almost all cases, is approximately 20%, or about one-fifth of the approximate breaking-strength of the rope, and would appear to be a factor of safety of five. This, however, is not the case, as will be shown, and it is important, in calculating the proper rope for a certain load with a required factor of safety, that this proper working-load should not be confused with the actual factor of safety. While the working-loads do not show approximately one-fifth of the breaking strength of the ropes, it does not by any means indicate that in operation the rope selected would have a factor of safety of five, due to the fact that in addition to the working-load, there are other stresses to be considered, the most important of which is the stress due to bending over the sheaves and drums.

If the rope to be used is operated over standard-size sheaves and drums, the general average of bending-stress equals about 10% of the approximate breaking-strength of the rope. For instance, in a cast-steel wire-rope 1 in. diam., composed of 6 strands and 19 wires to the strand, the approximate breaking strength of which is 30 tons, showing a proper working-load of one-fifth, or six tons, to be used on a minimum size sheave or drum of four feet, the bending-stress would be 2.70 tons, or nearly 9½% of the approximate breaking-strength of the rope. It is thus evident, that, by adding this 9½% to the load-stress, which is 20%, we have utilized 29½% of the ultimate, and instead of an apparent factor of safety of five, we actually have only 3.41, or less than 3½. This is still further reduced by the stress due to starting the load.

It is often impracticable to utilize the size of sheave or drum recommended by the manufacturer. In such cases the bending-stress will vary inversely as those diameters are greater or less. Assuming, in the above example, that two-foot diameter sheaves were used, the bending-stress would be 5.58 tons, or about 18½% of the breaking-strain; this, in addition to the working load, would be 38½% of the ultimate strength of the rope, reducing the factor of safety to 2.6. The total working-stress then would be greater than one-third of the ultimate breaking-strength of the rope when new and is not

*Abstract of paper read before the Mining Section of the National Safety Council.

considered good engineering practice. If sheaves twice the diameter of those recommended by the manufacturers, or 96 in., were used, the bending-stress would be only 1.4 tons or about $4\frac{1}{2}\%$ of the ultimate strength of the rope. By reducing the bending-stress to a minimum more economical service could be obtained, and in many cases a smaller diameter of rope could be applied, thereby increasing the efficiency of the rope, and promoting a saving in first cost.

Reverse-bends play an important part in the early let-down of a wire-rope. The underwind rope, in which there are reverse-bends, will invariably give a shorter service than the overwind rope. The difference in service of the two ropes varies, but from experience the overwind rope will give 10 to 25% more service. The underwind rope, as it comes off the head-sheave, has taken somewhat of a set, the permanence of which depends on the relation of the rope-diameter to the sheave-diameter; the smaller the sheave the greater the set. The rope now travels to the take-up drum, some distance away, and will wind in the opposite direction to that in which it came off the head-sheave; thus a reverse-bend is thrown into the rope, and, consequently, into the wires themselves. The rope cannot recover itself in most cases, for the set it received by the head-sheave is not entirely overcome before it strikes the take-up drum and consequently the effect of the latter bend is more severe.

Another cause for failure of wire-ropes can be attributed to repeated shocks. The effect of these overstrains, as they may be called, is shown by microscopic examination of the metal as leading to crystallization with a consequent embrittlement of the steel. The overlapping of the rope on the hoisting-drum, with occasional slipping of the top layer into the grooves made by the layer underneath, will, first, cause jerks which increase the load on the rope by an amount depending upon the slack between the drum and head-sheave, and, second, the inner series of wires will crush somewhat from the squeezing between the top and bottom layer and will assume a pear or bell-shape.

In this condition it is impossible for the inner wires to perform their proper function, and the outer wires will be forced to take more than their share of the stresses. They will assume the shape of their cushion, the inner series, causing trouble in the form of abrasion on themselves. Overlapping cannot be eliminated in most cases on account of the amount of rope that must be taken on the drum, but the point to emphasize is the fact that frequent inspection must be made in order to minimize accidents.

There are several methods of fastening ropes to the load, either by means of sockets or clips. Both of these can be made in such a manner as to break the rope before the connection gives out. In using sockets it was formerly thought necessary to turn in or bend back the strands or wires into the basket of the socket. This method is now replaced by opening the wires in the strand of the rope that is to be socketed, thoroughly

cleaning them with muriatic acid cut down with zinc, and pouring molten spelter on the straight wires. Tests of this method of socketing have proved that a more uniform strain on each individual wire can be depended upon. It necessitates great care and there is no possible means of inspection. The connection made with clips, if properly applied, is equally strong, and careful inspection can always be made. This connection should be made with the U-bolt section of the clip over the short end of the rope. This insures greater safety, as there is no indentation on the main section of the rope by the U-bolt.

Uses of Nitre-Cake

Nitre-cake is the product resulting from the reaction between sodium nitrate and sulphuric acid in the nitre-pots at sulphuric-acid works. These chemicals when combined and subjected to the heat of the sulphurous gases from either the pyrite or the sulphur-burners, evolves the nitrous fume necessary for the oxidation of the SO_2 in the gases to SO_3 . The resultant liquor in the nitre-pots, on being discharged into the air, solidifies and is then called nitre-cake. Theoretically it should be acid sodium sulphate (NaHSO_4), but actually it generally contains about 78% of that salt with 18% of Na_2SO_4 , and about 4% moisture. As an acid reagent it is equivalent to about 32% sulphuric acid, and the saturated solution corresponds approximately to 18% H_2SO_4 . The acid sodium sulphate, which is a waste-product from the manufacture of sulphuric acid, can be used as a substitute for that material in many industries, and thereby help to economize on this commodity, so essential in the making of munitions, fertilizers, and a thousand other necessities of modern civilization. Indeed, the acid sodium sulphate, which can now be had at many places for the cost of hauling it away, may be used directly in compost-heaps with raw ground phosphate rock, thereby converting it to soluble phosphate and leaving a sulphate of soda that is in itself beneficial as a fertilizer on many soils; it is valuable also for removing oxide and scale from articles of iron or steel, such as castings, forgings, pipe, bolts, nuts, and rivets, and from sheet-metal for galvanizing; it is useful as an acid wash, as a cream of tartar substitute for baking powder, as a bleaching agent in paper manufacture, for the production of hydrochloric acid by reaction with common salt; and for a large number of other purposes. It is the most practical substitute for sulphuric acid that is available, and its utilization is a matter of national concern.

NORTH CAROLINA, at the present time, produces about 1300 oz. gold and 700 oz. silver per annum. Copper to the extent of about 10,000 lb. is produced from Granville and Rowan counties. The possibilities of the State are much greater but development is retarded in part by difficulties over land-titles and still more by an exaggerated idea among the people as to the value of undeveloped mineral land.

AHMEEK STAMP-MILL

CALUMET SHAFT NO. 5

The Lake Superior Copper Country

By HOMER GUCK

The development of copper mining in the United States is as synonymous with the operation of the Calumet & Hecla as it is with the expansion of electricity. How the great Calumet conglomerate lode was discovered is still a matter of dispute. People in Michigan continue to believe that 53 years ago old man Royale's boarding-house pig stuck his snout into the Indian pit in the back yard of his road-house and unearthed a cache of copper. That was the story as told by E. J. Hulbert, the discoverer.

The fact remains that the discovery of the great conglomerate was due to mere chance. Hulbert was surveying a state road from Copper Harbor, the most northern point in the State of Michigan, to the south-west limit of what is now Houghton county. Royale's boarding-house was on the site of the Miscouaubik Club. It was a halt for overland passengers from Houghton to Eagle River, then the two larger towns. Centuries before, the

Indians, having dug their mass copper from Isle Royale, started south for the winter. Desiring to avoid Keeweenaw point, they went overland through the peninsula and were caught by an early winter. They dug a pit and buried their copper. Their pit happened to be right on the hanging wall of the conglomerate lode of the Calumet & Hecla and the present location of No. 1 shaft, Calumet mine, still in operation. The surmise is that George Agassiz, son of the late Alexander Agassiz, for many years the president and directing head of the property. The Indians never returned for their copper.

In the 17th century French explorers found copper on the Ontonagon river. This district was a virgin forest 73 years ago when the Chippeway Indians ceded it to the United States. Twenty years before the Civil War there was a copper boom, which subsided and left a few small mines in the forests then covering this part of Michigan. The search then was for mass and boulder

A MASS OF NATIVE COPPER

A MACHINE-DRILL AT WORK

copper. It was in 1858 that Hulbert made his discovery. At first he thought he had an old Indian mine. In examining the surface he found the conglomerate outcrop just south of the cache at what is now No. 1 Hecla shaft. This big block of conglomerate was wonderfully rich. Hulbert was unable to buy the tract at Hecla, but, keeping his discovery quiet, secured the Calumet property. He sank his first shaft at what now is No. 4 Calumet, and in the middle of September 1864 opened the conglomerate. Later he associated himself with Quincy A. Shaw of Boston. That gentleman furnished the funds by which the property was secured from the St. Mary's Mineral Land Company.

At the time of the Civil War the production of copper in the world was insignificant, the Rio Tinto mines of Spain producing the largest part of it. The metal sold as high as 52 cents per pound. At that time Michigan was just coming into prominence, the output being confined to so-called 'float' copper and masses found near the surface and handled directly in a smelter. The Quincy mine was then our largest producer. It got out two million pounds in one year. The Calumet & Hecla produces that much in three days now. By the way, the Quincy has paid dividends to its shareholders continuously from that time to this, missing just one year, during the Western Federation strike in 1913.

With the discovery of the Calumet conglomerate the whole system of getting out copper changed. In this district the conglomerate carries the copper in its pure state in particles from as small as a pin-point to the size of a fist. The Calumet conglomerate lode has paid at least \$150,000,000 in dividends to the shareholders of the Calumet & Hecla Corporation, and over \$300,000,000 in wages to thousands of employees and indirectly for maintenance and operation. In the early days the Calumet & Hecla ore was very rich. Each year it is becoming leaner. Some idea of the industrial problems this corporation has met and overcome may be gained from a brief explanation of the operation. First you sink your shaft, equip your plant, build your stamp-mill and smelters. All these things cost millions. But forget them. They are up and operating. Now to get copper out of the ground the miners go down a mile from the surface, then as much as half a mile from where they left the skip to the place where they operate a drill for six hours, punching holes into the copper-bearing rock. The holes are filled with powder and the ore blasted down. This ore, locally called 'rock,' is put into cars, pushed to the shaft, and dumped into the hoisting-car, or skip, to be hauled a mile to surface. At the top of the shaft the skip is dumped again and the ore goes through a series of crushing processes in the shaft-house itself, after which it is fed into cars to be hauled five or six miles to the stamp-mill, where it is dumped again, crushed into small pieces by stamp-heads having a pressure of five tons, jigged and crushed and rolled and washed on innumerable tables, re-ground again, and finally put through an acid and flotation process to prevent the

escape of the smallest particles of copper. Then the concentrate of native copper is hauled another mile from the mill to the smelter, where it is roasted, treated by electrolysis, and cast into cakes or bars or slabs, as the customer requires. Most of it is shipped to New York. For every ton of ore that is blasted down in the mine—for every 2000 pounds—there is extracted just 20 pounds, or 1%, of copper. The remainder, 1980 lb., goes into the lake.

To the reader of this technical magazine these statements sound like the elementary instruction of a mining college. I am telling it just as I do to every committee from the southern farming or city district of the lower peninsula of Michigan when they come to visit us and want to see a mine. They have no conception whatever of the enormity of the problem that takes a speck of copper from a point a mile or two from surface and puts it down on the New York dock at a profit; and too often our high-grade technical engineer passes over these details without a thought, giving no consideration to the things that are so obvious to him, accomplishments in which he himself has taken a part; accomplishments that are so much a matter of reality that he fails to appreciate their importance because of their familiarity.

A year ago all this was done at a cost of ten cents per pound. Now the cost is higher, probably 13 cents. That is due to the rise in wages and the increased cost of everything that is used in the operations. The Calumet & Hecla for itself and ten subsidiaries, employing 14,000 men, has just announced a continuation of the 10% bonus and the 5 cents per diem increase in pay for another six months.

In the early days richer ore closer to surface was worked. Then the miner got 100 pounds from every ton, and lost 30 lb. in the stamp-mill, and thought nothing of it. Now this old tailing is being worked over again and it is paying better than a new mine. That fact alone illustrates the metallurgical progress made at this wonderful mine. With the greater depth, with the leaner ore, it has been a man's problem to keep this great corporation up to its standard of earning capacity. And the man who took charge of this property when it seemed to be going the way of all mines was a Michigan product, James MacNaughton, now the first vice-president of the company. Today the total cost of mining and of bringing the ore to the surface through a mile or two of workings is one dollar per ton. And the miners are the best paid workmen in the world. Today their average wage is \$5 and many of my miner friends are cashing contract checks that run better than \$250 per month.

But the most wonderful thing about the Calumet & Hecla is its paternalism. When we had a strike here a few years ago, the only one in the history of the enterprise that amounted to anything, the cry of too much paternalism was raised. But it failed, as did the last dying effort of the Moyer-Mahoney gang of Western Federation agitators. The paternalism is not ostentatiously displayed, but it is none the less practical and effective. It gives the Calumet & Hecla the finest class of miners to be found anywhere.

Nickel-Copper Steel Direct From Sudbury Ores

By F. H. MASON

*While the component parts vary at different mines and in different parts of the same mine, the massive nickeliferous pyrrhotites of the Sudbury district of Ontario may be said roughly to contain:

Iron	40.0 %
Sulphur	30.0 "
Nickel	3.5 "
Copper	1.2 "
Gold	0.01 oz. per ton
Platinum	0.01 " " "
Silver	0.29 " " "

By the present method of reduction both the iron and sulphur are wholly lost, and when we consider that 70% of the nickel is used for alloying with steel to form nickel-steel, the wastefulness of the process is at once evident. It has long been the dream of the metallurgist to discover a process by which this waste can be avoided. The difficulty in the past has been threefold; first the complete elimination of the sulphur, second the rooted objection of metallurgists to the presence of copper in the resulting steel, and third the loss of the precious metals, which, of necessity, go into the pig, and hence into the steel. The first two of these objections have now been overcome. By improved methods, the sulphur content of the pulverized ore can be reduced to less than 0.5% by roasting in a Wedge furnace, and if, after smelting, the resultant pig is converted into steel in a basic-lined electric furnace the sulphur content of the steel is negligible. It is freely admitted that copper in excess of 0.75% will make steel red-short, for the reason that steel will not dissolve a greater amount, and the copper separates. But recent researches on nickel-copper steel alloys have demonstrated that when both nickel and copper are added to steel, if the ratio of copper to nickel is less than 1:3 the copper does not separate and consequently red-shortness does not ensue. This is readily explained by the fact that nickel is a solvent for both iron and copper and consequently holds the latter in a solid solution in the steel. It has been found, for instance, that 3.5% of monel metal, which contains 69% nickel, 29% copper, and 2% iron, added to steel makes an alloy substantially the same in mechanical and other properties as a 3.5% nickel-steel. The third objection, that of the loss of the precious metals in the pig, has not, and, from the light of our present knowledge, will not be overcome, but the loss is more than offset by the gain of the iron and of the cheaper metallurgical treatment. Besides, the precious metals are now lost in the manufacture of monel metal, and, at any rate in part, by the Orford process of re-

fining, as is proved by their presence in many of the International Nickel Co.'s products.

The first attempt to produce nickel-steel directly from the Sudbury ores was made by E. J. Sjöstedt more than ten years ago, at Sault Ste. Marie, under the auspices of the Canadian Department of Mines. A low-content nickel ore was selected with the view of keeping the nickel content of the pig as low as possible. The roasted ore contains 2.32% nickel, 0.41% copper, 45.8% iron, and 1.56% sulphur. The charge employed consisted of 400 lb. of ore, 105 lb. charcoal, and 40 lb. limestone. This was smelted in an electric furnace, and the resulting pig contained 4.1% nickel, 0.7% copper, 0.006% sulphur, 0.04% phosphorus. In all 14,500 lb. of ore was smelted and 7336 lb. of pig metal was produced. The power consumed was 0.39 hp.-yr. per 2000 lb. of pig produced, and the charcoal consumption was 55% of the weight of the metal obtained. Later, under Sjöstedt's direction, 168 tons of nickel-copper pig was produced at the rate of 1.34 tons per day in an electric furnace at Sault Ste. Marie. Some of this was converted into steel in a Heroult furnace at the plant of the Inalcomb Steel Co. To reduce the nickel content and make the resulting steel comparable with standard 3.5% nickel-steel, scrap-steel had to be added to the charge. The following are the results of chemical and physical tests of the copper-nickel steel, and for comparisons tests made at the same time of open-hearth nickel-steel:

ANALYSES

	Open-hearth nickel-steel	Copper-nickel steel
	%	%
Nickel	3.36	3.62
Copper	0.48
Carbon	0.46	0.44
Manganese	0.70	0.50
Sulphur	0.034	0.013
Phosphorus	0.021	0.013
Silicon	0.066	0.034

TENSILE STRENGTH AS ROLLED

	Open-hearth nickel-steel	Copper-nickel steel
Elastic limit, lb. per sq. in.	74,625	72,400
Tensile strength, lb. per sq. in.	122,000	115,000
Elongation in 2 in., per cent.	16	22
Reduction in area, per cent.	34	51

TENSILE STRENGTH ANNEALED

	Open-hearth nickel-steel	Copper-nickel steel
Elastic limit, lb. per sq. in.	64,750	63,750
Tensile strength, lb. per sq. in.	119,000	107,300
Elongation in 2 in., per cent.	17	25
Reduction in area, per cent.	37.5	48

*Based upon information given in the Report of the Royal Ontario Nickel Commission.

Tensile strength after quenching in oil from 1500° F. and re-heating to 800° F.

Elastic limit, lb. per sq. in.....	1,561,500	154,000
Tensile strength, lb. per sq. in.....	175,000	172,500
Elongation in 2 in., per cent.....	9.75	13.25
Reduction in area, per cent.....	30.8	49.1

These results, it will be seen, are in favor of the nickel-copper steel, for while the tensile strength is slightly less than that of the nickel-steel, the elongation is considerably greater. This may be due in part to the fact that it was made in an electric furnace, while the nickel-steel was made in an open-hearth furnace, but, be that as it may, the nickel-copper steel stands up to the requirements of a 3.5% nickel-steel. Still, notwithstanding the favorable tests, metallurgists refused to accept nickel-copper steel for structural purposes; it was barred in most specifications, and at the time of his death, Sjöstedt was working out a process for the economical removal of the copper prior to smelting the roasted ore.

At the request of the Royal Ontario Nickel Commission, Alfred Stansfield repeated Sjöstedt's experiments on a laboratory scale at McGill University and to a great extent corroborated his results. Mr. Stansfield did not produce as good a steel as that obtained by the Holcomb Steel Co., but, considering that he was working on a laboratory scale with charges that produced only from 14 to 20 lb. per pig, it was hardly to be expected. The following are the physical tests on the steel produced at McGill:

Elastic limit, lb. per sq. in.....	70,100
Yield point, lb. per sq. in.....	77,400
Maximum load, lb. per sq. in.....	101,500
Elongation in 2 in., per cent.....	18
Reduction in area, per cent.....	31.9

Many metallurgists still retain this prejudice against copper in steel, even in the face of the fact that the U. S. Government is using 8-in. shells of monel-metal steel and find that they pierce armor-plate equally as well as nickel-steel of the same percentage alloy.

The most interesting evidence given before the Nickel Commission with regard to the possibility of making nickel-copper steel directly from the Sudbury ores was that of G. M. Colvocoresses, general manager for the Consolidated Arizona Smelting Co., who owns a patent for manufacture of nickel-copper steel from nickeliferous pyrrhotite. Mr. Colvocoresses proposes to roast the ore in a Wedge or other mechanical furnace to 0.5% sulphur and then either nodulize it and smelt in a blast-furnace, like an ordinary iron ore, with coke and limestone, or smelt directly in an electric furnace. By whichever method the pig is obtained, Mr. Colvocoresses advises refining in an electric furnace. Mr. Stansfield, on the other hand, suggests as a cheaper method, nodulizing the roasted ore, smelting in a blast-furnace, bessemerizing the pig, and removing the last traces of sulphur in an electric furnace.

As the cost of producing the alloy, Mr. Colvocoresses offers the following figures: Mining \$2.50, crushing and roasting 50c., sintering and transportation \$1. So the

roasted and sintered ore would cost \$4, or \$8 per ton of pig. Coke \$2.25, lime 30c., electrodes 60c., electricity \$7, labor \$3, making a total of \$21.15 per ton of pig, and allowing 2008 lb. of pig to the ton of steel, comes to \$21.25. To this must be added burnt lime 30c., iron ore 20c., ferro-alloy and manganese 50c., electrodes 68c., electricity \$1.15, and labor \$3.80, bringing the total cost to \$27.88 per ton of refined steel, allowing \$2.12 for selling cost. This gives nickel-copper steel at \$30 per ton. The weak point in these figures seems to be that two tons of roasted ore should equal a ton of pig. Assuming 40% iron for the ore, which is what is generally allowed, the roasted ore would not be expected to contain more than 45% iron. This, however, would only make a difference of a dollar in the cost on the figures given. The value of the sulphur has not been taken into consideration because the cost of transporting sulphuric acid from Sudbury is prohibitive. In the light of more recent research, however, the possibility of producing elemental sulphur by the Hall or thioen process should be attractive.

Slush Castings

When a metal or carbon mold is filled with a metal or alloy of low melting-point and the latter, after standing a brief interval, is poured out of the mold again, a shell is left in the mold that takes its form and constitutes a hollow casting possessing a better proportioned wall-thickness than it is possible to get with cores. Such castings usually take the form of more or less artistic articles, such as statuettes for clocks, and lamp bases. The metal is generally zinc, and the metal parts made in this way are known as slush castings. It has been found that the purer the zinc used, the better the castings and the less trouble experienced from cracking. It is common to add a small amount of aluminum to the zinc, as it clears the surface of the metal and makes it run better. About 0.10% or less of aluminum is used, but it is a remarkable fact that, while 2 or 3% of aluminum will cause the zinc to become stiff and slushy, with 5% aluminum the zinc pours well and produces good castings. Since aluminum increases the cost of the zinc, it is generally used as a de-oxidizer for making slush castings, and not for producing an alloy, and the amount added is less than 0.10%. Some manufacturers have found that the addition of not to exceed 0.005% of aluminum increases the fluidity of the zinc and permits slush castings to be made that are free from cold-shuts and cracks. This small amount of aluminum is most conveniently added in the form of a mixing-alloy of zinc and aluminum.—Daily Metal Reporter.

THE equatorial radius of the earth has been computed by the U. S. Coast and Geodetic Survey to be 6,378,283 metres, while the polar radius is 6,356,865 metres. The limit of error falls within 34 metres of the actual length. The flattening at the poles is between 10/2987 and 10/2968 of the radii, with 10/2978 as the most probable value.

Welding Nickel Anodes

In these days of attempts at conservation of every possible waste material, any scheme with this end in view merits attention. It had been the custom to throw away small pieces of nickel anodes from plating-baths, but now the practice of utilizing every pound of nickel anodes for service by welding the scraps together has resulted in saving considerable money at many plating establishments. Until recent years it was usual to sell worn

ing them to fuse into one piece. The tacking of a joint requires but a moment, as the temperature of the oxy-acetylene flame, which is approximately 6300 F., causes the metal to fuse quickly. No flux is used. Where necessary another piece of scrap-nickel is used as a filling-rod. The same flame is also used to remove the brass hooks from the scraps, the solder melting rapidly, leaving the pure anode to be welded.

Several other methods of utilizing scrap-anodes have been tried in the past, but with uncertain results. The method of fastening them together by means of rivets and similar means are seldom dependable because of uncertain conductivity. It is impracticable for anyone but the manufacturer to re-melt and re-pour anodes, because in so doing the composition is changed. A decided advantage in welding the scraps together is that the original composition is not changed, and the fused joints insure conductivity equal to that of new anodes. Another advantage is the fact that no skill or experience in the art of welding is required to weld scrap-nickel anodes. Any workman of average intelligence can do it without previous knowledge of the process. The welding apparatus required is inexpensive. The illustration shows the welding of scrap anodes by the Prest-O-Lite process of oxy-acetylene welding. Welded anodes are seen in the foreground.

WELDING SCRAP NICKEL ANODES

anodes as scrap for want of a thoroughly satisfactory method of utilizing them, and this was a source of considerable loss to the platers, for the junk-value of such material is less than one-half the original cost of the anodes. By welding the scraps together every pound of the costly metal is utilized for plating at a trifling cost for welding. The practice of welding such anodes is as follows: The worn anodes, as they are withdrawn from the tanks, are turned over to some workman who does the welding. A scrap of suitable size and shape is selected as a hanger, and other scraps are tacked to it by welding until the desired size and weight are secured. The tacking consists of melting the scraps, at the point of welding, by the heat of the oxy-acetylene flame, allow-

Silver-Coinage Ratio

The United States ratio in dollar coinage is 15.988, which brings the gold coinage value of an ounce of fine silver to \$1.2929. Coinage of dollars has been discontinued since 1904. The weight of our subsidiary coinage, that is, half dollars, quarters, and dimes, is about 6.46% less in proportion to the silver dollar. As the fineness of the coins is the same, the seigniorage is correspondingly larger. Most other nations follow the same course. The Latin Union, comprising France, Italy, Switzerland, Belgium, and Greece, and those that have adopted the same system in whole or in part,

namely Spain, Rumania, Bulgaria, Servia, Russia, and Finland, have as a unit a silver coin on the basis of 1 to 15½, a ratio equal to a gold-coinage value of \$1.3336 per ounce of fine silver. The subsidiary silver of these countries is coined on the still smaller ratio of 1 to 14.38, equal to \$1.438 per fine ounce of silver. England's coinage is all on the ratio of 1 to 14.288; that of the German empire on 1 to 13.95. The Scandinavian countries have a monetary union, and their silver coins are minted on a ratio of 1 to 14.78, and Holland's silver coinage is all on a 1 to 15.63 basis. As far as European countries are concerned, it will be seen that the price of the white metal will stand a much higher valuation before coinage would have to be curtailed.

Chrome Brick in Copper Reverberatory Furnace

By FRANCIS R. PAYNE

*Several years ago one of the large Eastern copper refineries decided to utilize basic in place of silicious material in the walls of reverberatory furnaces for the treatment of fowl blister copper, as the latter rapidly corroded the silicious linings. It was expected that there would be less slag formation, with a consequent decrease in the cost of treatment and a reduction in the metal losses. Magnesite-brick was first used, but while the corrosive action of the fowl material was greatly reduced, and the amount of slag formed was much less, the magnesite proved to be unsatisfactory in parts of the furnace because of its tendency to crack and spall when subjected to alternate heating and cooling. It was decided to substitute chrome-brick in the parts of the furnace that were affected. The results, as far as the reverberatory furnace was concerned, were satisfactory. The corrosion was small and the amount of slag formed was no greater than when using magnesite, and the tendency shown to crack and spall was eliminated. Gradually the use of chrome-brick was extended to furnaces treating blister copper as well as those melting cathodes, and the results were so satisfactory that the silicious roofs were replaced by roofs of chrome-brick except where experience showed a more satisfactory performance on the part of the silica-brick. It was immediately recognized, both for the magnesite and chrome-brick, that the absorption of metal was heavy, but it was felt that the longer life of the furnaces and the decreased cost of slag treatment and metal losses would more than offset the disadvantage.

When repairs had to be made, the resulting 'cobbing' was sent to the blast-furnaces for the recovery of the copper, silver, and gold. It was, of course, realized that chrome was a neutral material and could not be fluxed, but it was thought that, at the blast-furnace temperature, the cobbing would be melted, releasing the absorbed metals and causing the chromium oxide to pass out mixed with the blast-furnace slag. For a time this method appeared to be satisfactory, but as more of the cobbing was made and treated in the blast-furnaces, trouble developed. The capacity of the settlers began to be seriously reduced and slag-losses increased, due to improper settling. It was found that there had formed in the settler, between the matte and the regular slag, a layer of thick mushy slag. This could not be fluxed, could not be tapped out with the matte, and would not of itself overflow through the slag-spout. The only way to remove it without shutting down and digging it out, was to insert a pipe into the layer and, by use of compressed air, cause it to mix and overflow with the regular

slag. While this procedure cleaned the settler, it also resulted in metal-losses that could not be tolerated. Samples of this mushy slag showed it to contain as high as 25% chromium oxide, indicating that the cause was in the chrome-cobbing added to the charge. On discontinuing the treatment of the cobbing, the trouble disappeared. The result was to accumulate a considerable stock of chrome-cobbing, and experiments were undertaken to devise a satisfactory process for the removal of the metals so as to leave a residue that could be sent to the dump.

The cobbing was crushed fine, thereby releasing the larger metallic particles, and treated in a reverberatory furnace with roasted pyritic ore and silica. This gave a fairly fluid slag in which the chromium was apparently soluble. A considerable amount of the metal was thus recovered, but the slag was still too rich in copper to throw away, and when sent to the blast-furnaces, induced a return of the former troubles in the settler. Fine crushing and fusion with a low-grade matte was expected to remove the metals and leave a slag sufficiently low in copper to be discarded. The results were unsatisfactory, for although the matte absorbed much of the metal, yet the slag was thick and pasty and contained considerable copper. It was believed that crushing, followed by mechanical concentration, might separate the metal from the brick. Accordingly, the material was crushed and screened to remove the coarse metallics, and was then treated on a Wilfley table. Sizing resulted, but little concentration took place. The entire structure of the brick proved to be saturated with finely divided copper and copper oxide. Flotation was also tried without success, as the concentrate was too rich in chromium and there was too much metal in the residue. The most satisfactory solution yet found for the disposal of this material is to grind it, thereby freeing the larger metallic particles, and utilize the fine material in the manufacture of refractory brick, thus using the cobbing over and over again. Some slagging occurs, of course, and a certain amount of chromium goes to the blast-furnace, where the mushy slag is formed, but in small amounts it is easily taken care of, and eventually the accumulated stock is 'worn out' and sent to the dump.

This experience suggests that chrome-brick is not very desirable for this class of work, and that magnesite should be used if possible. Experiments indicate that the tendency of the magnesite to crack and spall can be overcome by subjecting the brick to pressure before burning, which should also cause less absorption of metal. There is also no difficulty in treating the cobbing in the blast-furnace.

*Abstract: Bull. A. I. M. E.

Colorado Metal Production in 1917

The mine output of gold, silver, copper, lead, and zinc in Colorado for 11 months of 1917, and the estimated output for December, according to data compiled by Charles W. Henderson, of the U. S. Geological Survey, amount to about \$16,020,000 in gold, 7,327,000 oz. silver, 67,500,000 lb. recoverable lead, 8,700,000 lb. copper, and 114,000,000 lb. recoverable zinc, having a total value of nearly \$40,600,000, compared with \$19,153,821 in gold, 7,656,544 oz. silver, 70,914,087 lb. lead, 8,624,081 lb. copper, and 134,285,463 lb. zinc, having a total value of \$49,200,675 in 1916.

The lead smelters at Globe, Leadville, Pueblo, Durango, and Salida were operated about as in 1916, the ore coming from Arizona, Canada, Colorado, Idaho, South

Keokuk, Iowa. The Western zinc-oxide plant at Leadville was operated steadily on zinc-carbonate ores. Copper ore and cyanide precipitates were shipped from Colorado to the smelter at Omaha, Nebraska, and some copper and lead ores were shipped to plants in Utah.

As predicted in the six months' review of operations, the production from Cripple Creek was less than in 1916, but the production during the last six months of 1917 was somewhat larger than during the first six months.

THE LEADVILLE DISTRICT

CRIPPLE CREEK DISTRICT AND ADJOINING DISTRICTS

Dakota, and other States, and including a large amount of zinc residues from Kansas and Oklahoma smelters. The flotation plant installed in 1916 at the Durango smelter to remove the zinc from the zinc-lead sulphide ores of the San Juan region continued to be operated during 1917. The copper-matting plants at Ouray and Vulcan were idle. The United States Zinc Co.'s magnetic wet-concentration mill and zinc smelter at Pueblo were actively operated on zinc ores from Colorado and other Western States. The Western Chemical Co.'s acid plant and magnetic-separation wet-concentration mill at Denver and the Empire Zinc Co.'s 200-ton magnetic-separation plant at Canon City were operated steadily, both treating chiefly Leadville lead-zinc sulphide ores. The River Smelting & Refining Co.'s plant at Florence continued to treat zinc-lead-copper sulphide ores from several counties in Colorado, part of the product being forwarded to this company's electrolytic zinc plant at

and the total production of Cripple Creek for the year was \$10,549,000, a decrease of \$1,570,000. During the year the Roosevelt adit was continued so as to end at the Portland mine, not at the Golden Cycle-Vindicator mine, as originally intended. A cross-cut was also started toward the Cresson mine. The Portland company abandoned its plan of using the flotation process in its Independence mill and continued to use the cyanide process with considerably increased capacity. The Vindicator company continued its experiments with the flotation process. The Golden Cycle cyanidation mill, at Colorado City, and the Portland cyanidation mill, at Colorado Springs and Victor, were operated steadily. The yield from the small cyanide plants of the Cripple Creek district was not so large as usual and the shipments of smelting ore directly to smelters fell off considerably.

Lake county, chiefly Leadville, but including also the

Lackawanna Gulch, Sugar Loaf, St. Kevin, and the Wortman lode districts and the Arkansas River dredge district, produced \$1,208,000 in gold, 2,240,000 oz. silver, 20,000,000 lb. lead, 2,177,000 lb. copper, and 59,500,000 lb. zinc, having a total value of \$10,700,000, against \$1,720,440 in gold, 2,931,281 oz. silver, 2,621,675 lb. copper, 21,719,392 lb. lead, and 76,785,567 lb. zinc, having a total value of \$16,082,059, in 1916. Shipments of manganese-iron ore, manganese-silver fluxing ore, lead carbonate, and zinc-carbonate ores continued in increasing quantities from the Downtown district, unwatered in 1916. Some zinc-carbonate and zinc-sulphide ores were shipped from the Fryer Hill district, also unwatered in 1916, and considerable iron-sulphide ores were shipped from the unwatered Carbonate Hill district. The output of zinc carbonate from the Leadville district decreased heavily. The output of zinc carbonate was 68,500 tons of 19.6%, as compared with 85,513 tons of 21.52% in 1916. The zinc-sulphide smelting and concentrating ore was 130,000 tons of 21.7%, against 147,295 tons of 20.96% in 1916. The Derry Ranch dredge, below Malta, continued operations during the year.

The San Juan region of Dolores, La Plata, Ouray, San Juan, and San Miguel counties produced \$2,588,000 in gold, 2,556,000 oz. silver, 20,824,000 lb. lead, 3,745,000 lb. copper, and 6,700,000 lb. zinc, valued in all at \$8,100,000, against \$3,041,275 in gold, 2,224,311 oz. silver, 16,345,768 lb. lead, 3,072,199 lb. copper, and 5,364,209 lb. zinc, with a total value of \$7,107,294 in 1916. The San Miguel county mills maintained their production of gold, which was about \$2,000,000, and increased their production of silver to over 1,000,000 oz., but considerable quantities of the ore treated in these mills came from operations in Ouray county along the strike of the veins. San Juan county produced considerably less gold but made an appreciable increase in the output of silver and a large increase in the output of lead, copper, and zinc. The yield of zinc in Dolores county increased heavily, but the yield of the other metals fell off somewhat. In Ouray county there was naturally a heavy decrease in the output of gold, due to the idleness of the Camp Bird mill, both the mine and mill having been closed-down in August 1916 to await the completion of the low-level adit, which was driven steadily during 1917. This adit is to be 10,700 ft. long and will cut the Camp Bird 450 ft. below the present deepest workings and 800 ft. below workings of the next most important section.

Boulder, Gilpin, and Clear Creek counties produced \$808,000 in gold, 956,000 oz. silver, 1,240,000 lb. copper, 6,336,000 lb. lead, and 3,300,000 lb. zinc, as compared with \$1,001,489 in gold, 881,518 oz. silver, 1,243,756 lb. copper, 5,681,392 lb. lead, and 2,572,575 lb. zinc in 1916. Boulder county produced \$50,000 less gold and 12,000 oz. less silver, also less copper and lead. Clear Creek county increased its output of silver, lead, copper, and zinc, but decreased considerably its output of gold. The production of gold in Gilpin county fell off approximately \$100,000, but there was an increase in the output of

lead, and for the first time in years there was an output of zinc.

In Chaffee county the output of gold, lead, copper, and zinc fell off, but the output of silver increased. The output of Pitkin county (Aspen) was 649,000 oz. silver and 13,633,000 lb. lead, an increase of 71,000 oz. silver, but a decrease of nearly 4,000,000 lb. lead. The output of zinc from this county, however, increased approximately 300,000 pounds.

The production of Creede (Mineral county) fell off considerably, as did that of Gunnison county. Summit county produced \$623,000 in gold, 157,000 oz. silver, 620,000 lb. lead, 30,000 lb. copper, and 19,000,000 lb. zinc, as compared with \$673,891 in gold, 120,207 oz. silver, 14,581 lb. copper, 1,688,637 lb. lead, and 13,940,948 lb. zinc in 1916. The four gold dredges at Breckenridge produced about the same output as in 1916, but the output of pocket gold was not equal to that of 1916. During the later part of the year a new dredge was launched in this district. There was very little activity at Montezuma, but several properties continued to work at Kokomo.

Mining was active at Red Cliff, Eagle county, though the yield of zinc was somewhat less than in 1916. Some shipments were made from the Brush Creek district. The output from both lode and placer mines in Park county decreased. The output from the mines of Custer county was the largest for several years, and there was also a considerably increased production from the Kerber Creek district of Saguache county.

THE largest output of ground barytes is made by three Missouri companies. The establishment of a grinding-plant at Cartersville, Georgia, by Thompson-Weinman & Co. will do much toward increasing the production of Georgia and Alabama mines, as it will give a ready outlet for small lots of barytes mined from various deposits. It is reported that a company is contemplating the grinding of barytes at a plant near Los Angeles, California, now used for other purposes. Such a step might be welcomed by the Pacific Coast makers of mixed paints, who now obtain their ground barytes in the East and pay high freight-rates to the coast. White bleached and floated ground barytes is used in ready-mixed paints, in the rubber industry, and in making stiff heavy card-boards and papers. Off-color ground barytes is used in preparing colored mixed paints and in various chemical industries. There is at present a fair demand for domestic barytes. Quotations on prime white or floated material range from \$30 to \$36 per ton, and for off-color from \$22 to \$24. The output is increasing, but is retarded by shortage of labor and difficulties of transportation.

TAXING net earnings of mines alone, says Lewis E. Young, fails to reach the non-producing mine which yet may possess some value; also valuation based on net earnings may not take a proportionate share of revenue from mines.

REVIEW OF MINING

MAMMOTH, UTAH

MAY DAY.—TINTIC BONANZA.—TINTIC STANDARD.—EAGLE & BLUE BELL.—TINTIC MILLING.—DRAGON CON.

Owing to the holidays the metal output of the Tintic district was materially reduced during the week ended December 29, being almost 50% below normal. The shipments were as follows: Dragon, 26 cars; Chief Consolidated, 14; Eagle & Blue Bell, 14; Tintic Standard, 10; Centennial Eureka, 9; Iron Blossom, 8; Colorado, 6; Mammoth, 6; Grand Central, 5; Gold Chain, 5; Victoria, 4; Chief Con. manganese lease, 3; Empire mines, 2; Scranton, 2; Minnie Moore, 1; Golden Key, 1; Victor Con. 1; Yankee, 1; making a total of 118 cars.—While the past year has been an uneventful one for the May Day, the work which is now being done on the 700-ft. level to the east of the shaft is promising. Already some small bunches of ore have been found and it is hoped that a continuation of this work will result in the discovery of another orebody.—At a meeting which was held recently at Salt Lake City it was decided to turn over the stock of the Tintic Bonanza Mines Co. in exchange for shares of the Eureka Standard Con. M. Co. on a basis of 100 shares of Eureka Standard for 127 shares of stock in the Tintic Bonanza.—Today the Tintic Standard is one of the biggest mines in the district; there are thousands of tons of ore in sight and the company has a large tract of undeveloped ground, owning one of the largest tracts of mineral land in Tintic. A recent strike has been made a short distance to the north of the new shaft, where a large body of ore averages 70 oz. silver, \$5 to \$6 in gold, 10 to 12% lead, and from 2 to 3% copper. The main ore-channel has now been opened for 500 or 600 ft.—A report was received from D. E. McPherson, the superintendent of the Deseret Mountain property, that the station on the 300-ft. level of the new shaft had been completed and the work of sinking had been resumed. When the 300-ft. level was reached a cross-cut was run into the vein, which proved to be 30 ft. wide. The vein was 6 ft. wide at the surface. Two drifts have been run north and south on the vein from the cross-cut. The shaft will be sunk to the 500-ft. level as fast as possible.—The Plutus property is being developed at three different points. A drift is being driven from the Victoria shaft into the Plutus ground, another drift is being run from the Chief Consolidated workings, and a force of men is at work in the shaft. The shaft is down 400 ft., where a drift had been started to the south. At the time the Plutus was taken over by the Chief company the stock was selling at 14c., now it is up to 35c.—Eagle & Blue Bell Mining Co. is one of the district's heaviest producers, but has suffered more than any other mine on account of embargoes that smelting companies have placed on ore. The Eagle shipped a total of 625 carloads of ore, and it is estimated by the company's officials that this is not half the amount that the mine is capable of producing. The mine is equipped with gear capable of hoisting 300 tons per day, but at times during the past year it has almost been necessary to suspend operations because the embargo prevented the mine from shipping.—Iron Blossom Mining Co., controlled by Jesse Knight and associates of Provo, is the third largest producer in this district. During the past year this mine has sent out 1201 carloads of ore, and has paid regular quarterly dividends of 5c.

per share. The principal constituent of the ore is copper, although lead, silver, and gold are also present.—Tintic Milling Co. was organized over two years ago, and for several months has been operating a custom-mill at Silver City to treat the low-grade ores that cannot be shipped to the smelters. The plant has proved a successful enterprise, and is treating nearly 300 tons of ore daily. Five cars of precipitate have been shipped to the smelters, and four or five carloads of bullion have been marketed.—The Centennial Eureka Mining Co., known in this district as the Blue Rock, was purchased several years ago by the United States Smelting Co., and since has paid millions of dollars in dividends. For many years it was the heaviest producer in the district.—The Tintic Delaware is a new company organized to develop the Ekker group of 14 claims in the West Tintic mining district. Enough ore to load a couple of cars is already on the dump awaiting shipment, and the management intends to commence shipping shortly.—Mammoth mine is one of the oldest and heaviest producers of the camp. It is owned by Samuel McIntyre of Salt Lake City and during the year has sent out 739 carloads of good-grade ore.—The Dragon Consolidated Mining Co. is another company controlled by Jesse Knight and associates, and is one of the oldest mines in the district, having been a producer for more than 40 years. This year the mine leads the list of shippers, having produced 1774 carloads. An average of 34 carloads per week has been sent out, some of the low-grade ore going to the Tintic milling plant and thousands of tons of iron ore to the different smelting companies of the State for fluxing. The Dragon also is sending out considerable ore of a higher grade, which has enabled it this year to pay dividends for the first time in many years.—The Eureka King Mining Co. is a North Tintic property in the vicinity of the Lehi Tintic. Development work has been pushed during the past few months, and at present consists of a shaft which is down 350 ft. The property is owned by Salt Lake people. George Chioulos is managing the work there.—The Copper Leaf Mining Co. is a new company situated in the extreme eastern end of the district adjoining the Tintic Standard. The shaft is down 400 ft.—The North Beck Mining Co. shaft is nearing the 300-ft. level, and sinking is going along as rapidly as three shifts can handle the work.—The Gemini has shipped 457 carloads of ore during the past eleven months. This mine is controlled by Jackson McCrystal of Salt Lake City. The orebody on the 1600-ft. level is one of the biggest that has been found in this mine.

TONOPAH, NEVADA

TONOPAH MINING.—TONOPAH EXTENSION.—TONOPAH BELMONT.—WEST END CON.—JIM BUTLER.

The Tonopah Mining Co. shipped 25 bars of bullion valued at \$46,750. The 50th dividend amounting to 74c. per share has been declared and is payable January 21. The total dividends to date total \$14,275,000. At the Silver Top 35 ft. of development has been done, 17 ft. at the Mizpah, and 44 ft. at the Sandgrass. During the past week 2450 tons of ore was milled, averaging \$13 per ton. Last week's production was 1950 tons.—The Tonopah Extension Mining Co. milled 9219 tons of ore during November, resulting in a net profit of \$11,719. At

the No. 2 shaft 133 ft. of development has been done and 170 ft. at the Victor. At the No. 2 on the \$50-ft. level stoping continues on a 4-ft. face on the Murray vein. At the 1260-ft. level the Merger vein is being worked on a 4-ft. face and the O. K. vein on a 3-ft. face. East and west drifts from cross-cut 510 on the 1350-ft. level are unchanged. Raise No. 567 shows a 6-ft. face of ore. On the 1540-ft. level of the Victor raise No. 1593 made a connection with the level above. Low-grade ore was exposed by the raise. Work in the 1501 winze has been discontinued, pending the erection of an air-hoist. The face of the winze is still in ore. On the 1680-ft. level 1600 south cross-cut was extended 60 ft. The 1600 west drift advanced 32 ft. on a 7-ft. face of good ore. The face of the west drift is about 270 ft. from the west line, where the Cash Boy Consolidated Mining Co. has worked the vein at approximately the same level. Work in the east drift 1600 has been resumed, and shows a 3-ft. face of ore. The production the past week was 2380 tons.—The Tonopah Belmont Development Co. milled 10,310 tons of ore during November, resulting in a net profit of \$66,224. On the 800-ft. level the east drift from the south-east cross-cut No. 8013 shows a 3-ft. face of excellent ore, while the west drift shows 5 ft. of ore on the South vein. Raise No. 18 continues to advance on a 5-ft. face of ore on the South vein. On the 1000-ft. level raise No. 73 made a connection proving a fair body of ore. Last week's production was 2147 tons.—At the Ohio shaft of the West End Consolidated Mining Co. drift No. 535 continues in a full face of fair ore. Drift No. 536 made a connection with drift No. 531, proving an excellent body of ore along the strike of the vein. Winze No. 534 is in good ore. On the 555-ft. level drift No. 1 continues in a full face of ore. Raise No. 814 continues in a silicified zone. The stopes at the West End shaft show higher average grade. The output the past week was 959 tons.—The MacNamara Mining Co. cut the Ohio vein in a raise from the west cross-cut on the 700-ft. level. The vein is wide and of fair grade where it was cut by the raise. The production the past week was 512 tons.—The Jim Butler Tonopah Mining Co. milled 2916 tons of ore during November, resulting in a net profit of \$7143. Work has been suspended in the west cross-cut on the intermediate below the 500-ft. level and a raise started to cut the vein above. Raise No. 653 from the intermediate continues on a 4-ft. face of ore. The production during the past week was 559 tons.—On the 1000-ft. level of the North Star on a 2-ft. face of excellent ore a raise is being put up. An intermediate from the raise No. 1050 is being driven on a 2-ft. stringer of ore. A shipment of 56 tons was made last week.—The Montana produced 77 tons, the Rescue 68 tons, and miscellaneous 7 tons, making the week's production at Tonopah \$715 tons with a gross value of \$152,513.

MAYER, ARIZONA

GENERAL DEVELOPMENT CO.—ARIZONA BINGHAMPTON.—COPPER QUEEN.—CONSOLIDATED ARIZONA.

Announcement has been made by directors of the Jerome Copper Co. that ore has been found in the 930-ft. adit in the South Jerome district which was taken over last summer by the General Development Co. It is considered to be one of the most important strikes of ore made during the past year. The vein is about 30 ft. wide, and is a milling-grade of copper-silver ore. Drifts have been started each way on the vein and cross-cutting is in progress, with ore still in the face. J. G. Flinn, the mine superintendent, states that the mine indications could not be better. This strike is of importance to the district because it is the first property to be taken over in the Jerome-Phoenix mineralized belt by this strong Eastern company, and the success of the first attempt will stimulate the company to further development on other properties in the district. The company owns the Christmas mine, three miles east of Mayer, which was the first one acquired last summer.

The Christmas mine is right in line with the Arizona Binghampton and Copper Queen mines on the south extension, with only a few claims between. There are places opened up that will run better than 20% copper. The discovery at the Jerome mine is especially gratifying to E. A. Kastner and Homer King, of Prescott, who were instrumental in interesting the General Development Co. in this district.—The Arizona Binghampton company has begun to sink the 600-ft. shaft to the 1200-ft. level. The new shaft is to be three-compartment and there will be a station cut at the 700 or 800-ft. levels. The sinking of this shaft will be watched with great interest for it will determine what may be expected with depth in the Yavapai schist. The main orebody on the 600-ft. level is 51 ft. wide and it is all a milling-grade of copper ore. This same orebody has come down through the several levels above, getting wider and better in grade with depth.—Over the divide from the A B C mine, the Copper Queen company has discovered new ore in a raise from the bottom of the 300-ft. winze. The ore-shoot has widened to seven feet and runs 5 to 6% copper. The development work is now being confined to the winze level. There are a number of promising outcrops on the surface that have not as yet been prospected.—While no public announcement has been made by the Consolidated Arizona Co. as to the success of the new work on the 1200-ft. level in the Blue Pell mine, it is commonly reported that some ore has been found in the drift to the north that runs higher in gold and about the same in copper as the big orebodies on the 1000-ft. level. On the 1000-ft. level there are stopes 40 ft. wide of milling and smelting grades, and now on the 1200-ft. level the ore found is proving richer. Recent development at the extreme south end of the Blue Pell mine, about 2000 ft. south of the main shaft, has opened an orebody better than 25 ft. wide at a depth of 75 ft. The company plans to run a drift on the 800-ft. level southward to open the new strike at depth.—The new strike in the Pocahtontas mine is continuing to grow better every day. The vein is about 12 ft. wide with portions running into high-grade shipping-ore. Some of the machinery has arrived for the new flotation mill. Another promising strike of silver-lead-gold ore has been made in the Black Diamond mine, near Walker, the control of which is owned by J. Irwin, of Prescott. The ore, which covers the bottom of the shaft, runs from \$50 to \$80 per ton in gold, silver, lead, and copper.

COBALT, ONTARIO

SILVER PRODUCTION.—TEMISKAMING.—MCKINLEY-DARRAGH.

The year just ended has been a profitable one for the mines of Cobalt. Of the \$16,000,000 produced during the year approximately \$8,600,000 is net profit. Of the latter amount about \$5,500,000 has been disbursed in dividends, and the balance employed in new ventures farther north in the endeavor to acquire new mining property. During the year the price of silver has averaged about 81.7c. per ounce, which compares with 65.6c. in 1916 and 49.7c. in 1915. The current year's increase above that of 1915 just about makes the difference between profit and loss.—During last week the Mining Corporation and the Nipissing company shipped bullion valued at approximately \$200,000. In addition to sending out large shipments of ore, the Mining Corporation has shipped 4,051,966 oz. during the current year. The output from the Nipissing is second only to that of the Mining Corporation; Kerr Lake ranks next.

The O'Brien mine is maintaining a large silver production, the output for the current year being about 100,000 oz. per month; the Miller Lake O'Brien, at Gowganda, is yielding about 84,000 oz. per month.—At the lower levels of the McKinley-Darragh a large tonnage of low-grade ore is being opened up, and some high-grade is also found. The physical condition of the mine is good.—The Chambers Ferland has

found some patches of high-grade ore just above the contact, and here too, considerable low-grade is being broken. The exploration at depth is now well under way and quite an extensive portion of the property heretofore unexplored is in line for early development.

The oil-flotation plant at the McKinley-Darragh has been closed down for the winter and will be re-opened in the early spring. The plant was only completed during the past few weeks, and was kept in operation just long enough to prove it to be satisfactory. However, the economic treatment of the sand from the bed of Cobalt lake could not be carried on during the cold weather. Underground operations at the McKinley-Darragh are of a favorable nature.

TORONTO, ONTARIO

CANADIAN METAL OUTPUT.—GROCH FLOTATION MACHINE.—MCINTYRE.—SCHUMACHER.—CONIAGAS.

The Canadian Department of Mines estimates the value of the total mineral production of Canada during 1917 at approximately \$200,000,000, as compared with \$177,201,534 in 1916. The output of nickel, lead, zinc, pig-iron, and steel showed a considerable increase, while there was a decline in the production of gold, silver, and copper. The principal metallic items were, gold \$17,000,000, silver 23,500,000 oz., copper 113,000,000 lb., nickel \$4,800,000 lb., lead 56,700,000 lb., zinc 31,000,000 lb., pig-iron 1,186,000 tons, and steel ingots and direct steel castings, 1,735,000 tons. Coal was produced to the amount of about 14,100,000 tons.—The seriousness of the coal situation, which is causing much hardship and loss at many points in eastern Canada, again is directing attention to the extensive peat deposits that might furnish a source of fuel to take the place of the uncertain supply of imported coal. Attempts have been made from time to time, under Government direction, to produce a peat fuel that could compete successfully with coal, but although a satisfactory fuel was produced the experiments proved commercial failures. Now, however, owing to the scarcity and steadily increasing price of coal, conditions have changed so radically that such a scheme would have far better prospects of success than when formerly attempted. Attention is being drawn to extensive peat bogs a few miles south of Cochrane in northern Ontario as a source of excellent raw material for peat-fuel manufacture. In October last a survey of these deposits was made by A. Anrep, an expert of the Canadian Mines Branch, who is in favor of the project, which is expected before long to take practical shape.

The Groch centrifugal flotation system is coming into favor and is being introduced for the treatment of other metals than silver. It has been for some time in successful operation for gold extraction at the Miller Independence mine, Boston Creek, and the McIntyre of Porcupine is arranging to try a Groch machine for experimental work. The system is stated to be suited also for the treatment of molybdenite, graphite, and the recovery of copper from sulphide. A contract has been let for the installation of a flotation plant on a molybdenite property near Amos, on the Transcontinental Railway. The Groch machine is a Canadian invention.

The McIntyre, which recently declared a 5% dividend, is at present the only dividend-paying mine in Porcupine. It is understood that current earnings are considerably in excess of the dividend requirements of 20% per annum. The ore-reserve has been increased considerably by underground operations. A new hoist has been erected with a capacity for operating to a depth of 2000 ft. Some delay was occasioned by water in sinking the shaft on the Jupiter property, but new pumping equipment has overcome the difficulty and the shaft has now nearly reached the 1000-ft. level.—The Schumacher has improved its position lately. Its main workings have been carried to the 600-ft. level and, despite labor shortage, the mill

has been kept operating to capacity. Following the example of other successful mines, deep mining will be undertaken and the shaft put down to the 1000-ft. level.—The Davidson has received all of its mill machinery and it is expected that the mill will be ready for operation in about a month. There is \$80,000 worth of ore on the dump and enough blocked out underground to keep the mill in operation for two years. The West Dome Consolidated has made arrangements to have its ore treated at the Dome Lake mill. It has 900 tons of \$17 ore broken and ready to be hoisted and 6000 tons of ore, running \$9 per ton, on the dump. The continuation of the main ore-body of the Porcupine Crown has been cut on the 1000-ft. level, where the ore compares favorably with that of the upper levels.

The Coniagas, of Cobalt, is sinking a 3-compartment shaft on the Ankerite gold property which it acquired recently. Progress is being made at the rate of seven feet per day, which, it is claimed, establishes a new record for quick sinking in northern Ontario. At the annual meeting of the Coniagas Mines on December 31, it was announced that \$500,000 had been paid in dividends during the year, bringing the total distribution to shareholders up to \$8,740,000. The output of silver was 1,344,267 oz. as compared with about 1,750,000 the previous year. The directors of the Peterson Lake have decided to proceed as soon as possible with the erection of a mill for the treatment of slime on the Seneca Superior dump. An offer, made by the Beaver Consolidated to the Temiskaming of the right to purchase over \$70,000 shares of the Kirkland Lake at 40c. per share, giving them an equal interest, was submitted to, and rejected by, the Temiskaming shareholders December 28.

LEADVILLE, COLORADO

METAL PRODUCTION.—MANGANESE AND MOLYBDENUM ORES.

METAL PRODUCTION FROM LEADVILLE MINES FOR 1917

Product	Quantity	Market value	Total value
Gold	60,540 oz.	\$20.67	\$1,251,528
Silver	2,488,238 oz.	0.8139	2,025,177
Lead	24,952,777 lb.	0.0871	2,169,032
Copper	2,592,943 lb.	0.2726	707,109
Spelter	85,389,235 lb.	0.0873	7,454,481
Manganese	36,272 tons	120.00	4,352,640
Total			\$17,959,967
Total for 1916.....			16,169,557

Increase in 1917	\$1,790,410
Grand total value of Leadville output to date....	465,563,133

ORE TONNAGE FROM LEADVILLE MINES IN 1917

Carbonate	8,734
Iron (oxidized)	32,073
Manganese	185,391
Zinc (all classes)	214,676
Sulphide (other than zinc).....	143,701
Silicious	10,152
Total	594,727
Total tonnage for 1916.....	455,729

Increase in 1917.....	138,998
Average value per ton of ore produced in 1917.....	\$30.20
Average value per ton of ore produced in 1916.....	35.45

Last year the mines of the Leadville district reached their maximum output and set up a new record for gross value of production. The one dominant factor that made possible this remarkable success was manganese. With the exception of lead, all other metals registered a loss as compared with the totals of 1916. Lead showed a gain of 2,200,000 lb. in output

and an increase of over \$250,000 in value. Gold fell off 20,500 oz. with a loss of \$500,000 in value. Silver, in spite of an increase in value over 1916 of 16c. per ounce, registered a loss in production of over 600,000 oz.; copper dropped over \$87,000; and spelter nearly \$2,000,000. To make up this total loss of nearly \$3,000,000 and still show a gain of \$1,750,000 over 1916, manganese closed the year with an increase in tonnage of 103,023 tons. In arriving at the gross value of the manganese output it was necessary to estimate as closely as possible the metal content of the ore and rate it at the highest market quotation. The total production of 185,391 tons of ore represents the wet product as extracted from the mines. Moisture was figured at 15% and reduced from the total, leaving 157,483 dry tons. The average manganese content of this ore, conservatively estimated, was 23%, giving 36,272 tons of metallic manganese. Eastern markets quote manganese at \$1.20 per unit on a basis of 48%; and so \$120 per ton was used in computing the gross value of the Leadville product. There is a great difference, however, in the price paid to the ore producers that offered the metal in Eastern markets. The highest contract now known to govern shipments from the Leadville mines calls for a price of \$10.50 per ton for 30% ore f.o.b. Leadville. This particular ore is shipped to Pennsylvania and is subjected to a freight charge of \$14 per ton, making the total cost to the buyer \$24.50. From \$10.50, the price at the mine runs as low as \$4.50, according to the grade of ore. Beginning as early as November of 1916, there was a marked increase in the development of manganese ores. The War brought a steadily growing demand for the metal; and, particularly after the bottoms used in the manganese trade with Spain and South America were being taken up by the Government for other service, the demand rapidly became acute. The market for the ore grew stronger, and with the increased price made a profitable outlet for low-grade material. In 1916 practically all of the Leadville manganese output, amounting to 80,000 tons per year, was shipped to the Colorado Fuel & Iron Works at Pueblo. The bulk of this tonnage was produced by the Star Consolidated Mining Co., which extracts an ore averaging 20% manganese. Some better-grade material was mined in the properties on Poverty Flats but the tonnage was small.—Early in 1917, Eastern ore-buyers made their appearance in the Leadville district and awakened a new interest in manganese. Several large deposits of ore that would average 30% were soon uncovered, the most important discoveries being at the Nisi Prius in Iowa gulch; Bohem, Grey Eagle, Penrose, and Northern in the Down Town section; Fairview on Poverty Flats; Lime and Bulls-eye on Iron hill; and Carbonate on Carbonate hill. These properties all became active producers in 1917 and shipped a heavy tonnage, much of the ore being sent to Eastern buyers, where better prices are secured than are offered at Pueblo. The future of manganese is regarded as bright so far as Leadville is concerned. The output for 1918 is expected to double that of last year and higher prices are looked for coupled with a demand for a still lower-grade product. A number of new enterprises are now being started with the purpose of opening new manganese orebodies.

Aside from the manganese properties, seven big companies stood out last year as the real backbone of the district. The Yak Mining, Milling & Tunnel Co., half of which was sold recently to the American Smelting & Refining Co., was the heaviest producer with a total of over 70,000 tons. The Wolf-tone shaft of the Western Mining Co., followed with approximately 66,000 tons. The Ibez Mining Co. showed a total output of 50,000 tons; the Star Consolidated Mining Co., 60,000 tons; the Down Town Mines Co., 40,000; the Leadville Unit, 40,000; and the Iron Silver Mining Co., 40,000. Numerous smaller properties combined to make up the remainder of the total output.—The work accomplished by Warren F. Page, manager for the Luema Mining Co., was the most important devel-

opment undertaken in new territory during the year. A cross-cut from the 300-ft. level of the Valley shaft was carried 900 ft. north under Prospect mountain and an immense deposit of low-grade sulphide ore was found in the white lime. A former adit driven from surface near the Valley shaft reached upper-contact ore 1700 ft. from the portal. The presence of the two main Leadville ore-zones under Prospect mountain is now determined. Another big adit to be driven from the Arkansas valley, east under the mountain, is planned for the coming spring.—The re-opening of the old Mikado shaft on Iron hill by the Iron Silver Mining Co., and the discovery last year of immense bodies of rich lead-zinc-silver sulphide ores in the lower reaches of the property was an important event that promises to result in making this mine the biggest producer in the district. The sinking of the Mikado shaft from its present depth of 1135 ft. to 1500 ft. is to be undertaken at some future date to fully develop the ore deposits now uncovered.—At the Wolf-tone shaft of the Western Mining Co., draining to the bottom level, 1250 ft., has resulted in the discovery of three huge bodies of sulphide ore. These have been found in the Wolf-tone, Mahala, and Maid of Erin claims, and rank with the biggest ore-shoots now open in the district. The sinking of the Wolf-tone shaft to greater depth is also to be undertaken.

The Down Town Mines Co., operating through the Penrose shaft, has made a number of important discoveries. Large orebodies have been found on five levels ranging from 300 to 900 ft. in depth. Iron, silver, manganese, lead, copper, and zinc are being produced. The company plans to re-open the old Coronado shaft for hoisting, as much of the ore now blocked out is in this property.—The sale of one-half interest in the Yak to the A. S. & R. Co., and the transfer of the management to the latter corporation is the biggest transaction of the past year. The price paid is stated to have been \$500,000. Under the new control, vigorous and extensive development throughout the property is to be undertaken; and it is believed by some authorities that the old objective of the big ore, the piercing of Mosquito range and reaching of the rich gold veins of Park county, will be included in the campaign.

Although not in the Leadville district proper, the recent discoveries of molybdenum at Climax, just over the line in Summit county, are of the greatest importance. During the past year three strong corporations, the American Metal Co., Molybdenum Products Co., and Pingrey Mines Co., entered the field, and the two first mentioned are now erecting milling plants and carrying on development in their holdings. The Pingrey company plans to begin work this spring. A satisfactory process of treatment has been perfected by each of these concerns, and it is believed that a large tonnage of ore will be concentrated during the present year.—The molybdenum deposit on Bartlett mountain near Climax was first discovered several years ago by Charles J. Senter, pioneer prospector of the Ten Mile, or Robinson, mining district, who has made repeated efforts to attract the interest of both American and foreign steel manufacturers to this remarkable deposit. These efforts failed to bear any fruit until 1915, after the War broke out. Then the value of molybdenum was demonstrated fully. England soon perfected a process for using molybdenum in steel and sought a supply of the metal. America was then aroused to the importance of uncovering large deposits of molybdenum, and a market for the metal was established. O. A. King, manager for the Pingrey Mines Co., was first to see the great possibilities of the Bartlett mountain deposits. In 1915 he had a trial lot of 1000 tons of the ore extracted from his property at Climax and treated by flotation at the Leadville district mill.—The results of this experiment were satisfactory, the finished product being sold for \$35 per unit. At that time, however, there was no assurance for a continued market for the metal, but now it is possible to make long-term contracts for the product.

THE MINING SUMMARY

ALASKA

(Special Correspondence).—Contradictory to a previous report, it is learned on authority that the Willow Creek Mining Co. has not surrendered its lease on the Gold Bullion. It now has a force of men freighting supplies and it plans to drive two headings in the mine during the winter with a view to developing ore.—Herschel Parker of New York reported finding platinum generally distributed in the gravels of streams heading in the Mt. McKinley region. It is not known if in commercial quantity, but the hope is entertained that the combined gold and platinum will make possible the successful exploitation of large areas of dredging ground.—From near Seldovia, on Kenai peninsula, chromite ore carrying 50% chromic oxide was mined and shipped; deposits of chromite and magnetite were reported from near Snug Harbor.

Anchorage, December 20.

ARIZONA

MARICOPA COUNTY

(Special Correspondence).—Messrs. Warnock and Holmes have taken a bond and lease on the Copper Belt property in the Harqua Hala mountains, 20 miles from Aguila. A road is being built to connect with the road now used for hauling manganese ore to Aguila when complete shipping will commence. The ore is said to run 20% copper and \$12 gold.

Phoenix, December 28.

MOHAVE COUNTY

(Special Correspondence).—A low-level adit has been commenced by the Arizona Butte Mines Co., to cross-cut and develop the many veins which are known to exist in Stockton hill; it will be driven on the Prince George vein.—Considerable progress is being made in the mines of the Union Pass district.—A two-stamp mill is being built at the Arabian property.—A cross-cut on the 400-ft. level to cut the Sheepshead vein is being driven at the Banner.—The shaft on the Lucky Prince is nearing 200 ft. in depth.—It is expected that diamond-drilling will commence within a few days at the Grand Island property. Two 1000-ft. holes are planned.

Kingman, December 28.

YAVAPAI COUNTY

(Special Correspondence).—It is reported that a 6-ft. vein carrying lead, copper, and silver to the value of \$100 per ton has been cut in the 200-ft. level of the Black Diamond.—The shaft of the Arizona Venture has reached a depth of 570 ft. At the 600-ft. level a station will be cut and the orebody will be developed.—The financing of the Copper Valley Mining Co. has been arranged. Work will commence immediately on the road from the mine to Skull Valley station and the shaft on the Snow Drift claim will be sunk on the 500-ft. level.—The south cross-cut on the 700-ft. level of the Verde Combination is 10 ft. in the body of quartz carrying iron pyrite and a little chalcopryite. It is estimated that the contact is about 15 ft. ahead of the present face.—The Arizona Power Co. has finished the new electric-power line into the Bradshaw mountains. The line is to be extended south into Tiger camp.—The management of the Arizona Binghamton has decided to continue sinking the main shaft from the 600-ft. level

to the 1200-ft. level. The present output is 175 tons per day; it runs 34% copper.—Funds have been raised to continue development at the Montezuma mine at Crown King.—The Palo Verde copper mine in the Black Canyon district is now being worked. Ten tons of ore per day from the old dumps is being shipped by motor-truck to Glendale.—Four feet of fair ore has been struck in the cross-cut which the Jerome Copper Co. is driving to cut the main orebody at the contact.—A new compressor and hoisting engine has been purchased by the Jerome Superior.

Prescott, December 29.

YUMA COUNTY

(Special Correspondence).—The new 300-ton mill at the Red Cloud Consolidated Mines Co., is in operation. It is estimated that there is sufficient ore developed on the Red Cloud orebody to run the mill for five years. Another orebody to the south has two years' supply of ore developed. The ore is silver-lead but carries some gold and molybdenum.—The Cobrita Copper Co. is sinking a shaft on the 200-ft. level to open up a shoot of high-grade ore that was cut under the old management. The ore-shoot in the drift shows a width of two feet and runs 17% copper and \$15 in gold.—T. J. Rogers has interested Prescott people in financing his Emery group of claims in the Buckskin mountains. In the past eight months six carloads of copper-gold ore has been shipped from the property. The present backers have agreed to install a compressor and other machinery, and drive the adit 400 feet.

Bouse, December 31.

CALIFORNIA

ELDORADO COUNTY

(Special Correspondence).—A vein of an average width of 15 in. assaying \$21.12 gold and 7.02% copper has been opened on the Sporting-Boy lode claim, according to Frank C. Fox, the manager. The vein extends 1400 ft. on the claim, and pans free gold for its entire length. The property is being systematically developed by a double-compartment shaft, for preliminary work, three stamp-mills will be erected with which to make mill-tests of the ore as the development of the vein progresses. The property is situated about five miles west of Placerville, on the lower road to Coloma, in the Cold Springs district.

Placerville, January 2.

KERN COUNTY

(Special Correspondence).—John W. Kelly has discovered platinum in a placer mine at the head of Cuyama valley. The material was identified as platinum in the Kern county assay office.

Bakersfield, January 3.

PLACER COUNTY

(Special Correspondence).—After being idle for 33 years the Rising Sun quartz-gold mine, one mile west of Colfax, is active. The property was lately taken under lease by D. A. Russell and Lee Gray of Colfax, and is being operated on a royalty basis by Martin & Hathaway of Nevada City. A 10-stamp sampling-mill and cyanide unit have been installed and good ore is being developed. Particular attention for the present

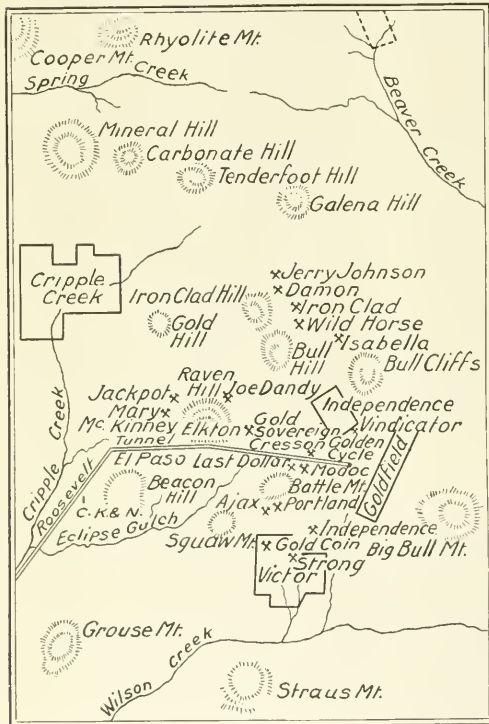

will be devoted to milling of ore from the old dumps and re-treatment of large quantities of old tailing. The Rising Sun is 725 ft. deep, and the mine is said to have produced \$1,500,000. —Several properties in the Last Chance district are active, including the Home Ticket, Pacific, and other good producers. Large quantities of supplies have been stored for the winter season; the unusually favorable weather of the past few weeks has facilitated operations.

Cofax, January 7.

COLORADO

TELLER COUNTY

(Special Correspondence.)—Including the December output of 95,750 tons of ore, averaging \$12.45 per ton, and having a gross bullion value of \$1,073,500, the output of the district for 1917 has totaled 1,006,072 tons, having a gross bullion value of \$12,533,177. For the first time in the life of the gold camp the output has exceeded 1,000,000 tons; the average value was

PART OF COLORADO

\$12.45 per ton. This heavy tonnage was made possible by the treatment of low-grade dump and ore rejected by the mills of the Cripple Creek district. The two mills of the Portland Gold Mining Co. alone treated 476,050 tons and recovered \$899,255. The Victor mill, on Battle mountain, treated 224,195 tons averaging \$2.18 per ton, and the Independence mill, originally built by the British Corporation Stratton's Independence, Ltd., but re-modeled by the Portland company, commencing in May, treated 251,855 tons averaging \$2.08 per ton. Other local milling plants brought the total tonnage of low-grade ores treated to 494,500, with an average value of \$2.11 per ton, and a total bullion value of \$1,045,294.

Eight mining companies of the Cripple Creek district paid

dividends amounting to \$2,674,441 during the year. The companies and the respective rates and amounts follow: Cresson Consolidated twelve dividends of 10c. per share, \$1,464,000; Golden Cycle twelve dividends of 3c. per share, \$540,000; Portland Gold Mining Co., four dividends of 3c. per share, \$380,000; Vinicator Consolidated four dividends of 3c. per share, \$180,000; Granite Gold Mining Co. three dividends at 2c. per share, \$49,500; United Gold Mines Co. one 1c. dividend, \$40,000; Doctor-Jack Pot Mining Co. one 1c. dividend, \$28,441.42; Jack Pot Mining Co. one dividend, \$12,500. The last named company owns 1,000,000 shares of Doctor-Jack Pot Mining Co. stock and the dividend was paid from this company's dividend.

At the Vinicator Gold mine the Golden Cycle and Vinicator No. 1 shafts continue to produce ore at the bottom levels, 1950 ft. in the Vinicator and 2100 ft. in the Golden Cycle. These deep discoveries have led to deeper development on other properties. The shaft at the Rose Nicol on Battle mountain has been sunk to 1000 ft. by the Camp Bird company. The Modoc Consolidated Co. has its new vertical Frankenberg shaft completed and timbered to a depth of 1100 ft. The Millasier Mining Co. has sunk the Clyde shaft on Battle mountain to a depth of 1500 ft., and the Cresson Consolidated has sunk the main shaft to 1750 ft. and has added an ore-reserve estimated at \$1,000,000.—The Roosevelt tunnel of the Cripple Creek Deep Drainage & Tunnel Co. has been advanced 1800 ft. The heading is now in Rose Nicol territory, on the north-western slope of Battle mountain, a total distance of 23,715 ft. from the portal. The work was started in July 1907. The flow from the tunnel has dropped to 4000 gal. per minute and the district has been effectively drained to a depth of 2000 ft. —Mining operations during the past year have been handicapped by labor shortage, many miners having left for silver, copper, and zinc camps, where a higher scale of wages obtains, although the scale was raised in the gold camp to a minimum of \$3.50 per day. Operating expenses were further increased by the high cost of explosives and mining supplies. New work, however, has been undertaken, in several sections of the district, and the prospects for 1918 are for normal conditions and production.

Cripple Creek, January 5.

In the Cripple Creek district Carl Evans, superintendent for the United Gold Mines Co., has opened a new body of milling-grade ore at the 500-ft. level of the Wild Horse mine near Midway, on Bull hill, and has commenced hoisting. A shipment of the ore will be loaded out shortly, and with the shoot holding up as expected, production will be steady. The development work at the 1250-ft., or bottom, level continues to be satisfactory.

KANSAS

CHEROKEE COUNTY

Some rich blende assaying 64% zinc has been taken from the Merrill mine south-west of Baxter Springs. The ore that assayed so rich was in the form of crystals and was almost prismatic. The average assay record of the ore in this mine is higher than many others which are considered good producers. The Merrill Mining Co. is capitalized at \$750,000 and was the first mining concern in this field to put up a lodge for the members of the firm, and another for the workmen and mine operators. The orebodies were discovered in the drill-holes at the 160-ft. level. In one hole the drill-cuttings indicated a 41-ft. face of lead and underneath a 23-ft. face of jack. The members of the company are W. E. Merrill, president; G. Huttig, secretary and treasurer; A. C. Wallace, vice-president.

The Dick Turpin concentrating plant, situated on a lease of the Rising land, south-west of Joplin, has been purchased by the American Metal Co. and will be moved in the near future to the company's recently acquired leases west of Baxter Springs. The Dick Turpin mill was built by D. W. Sparks and

associates about two years ago and is one of the good mills of the district. It will be moved to a tract of the R. F. Hartley land, where a mill-site has been graded.

Final details in the sale of the Miami Zinc Syndicate's tract west of Baxter to the American Metal Co. have been closed. The purchase price has not been made public.

MISSOURI

JASPER COUNTY

The Butte-Kansas mining plant at Waco was destroyed by fire on Christmas morning, with a loss estimated at \$75,000. There was \$50,000 insurance. The origin of the fire is unknown. The mill was completed only a week ago and had just started making concentrate. It was a 400-ton plant, being one of the good ones of the field, and was built on the Coyne lease of Hurlbnt land, just north of the Liberal mine and south of the Waco Mining Co. property. A portion of the equipment was obtained from the Meadville Mining Co. property, at Carterville, but much new machinery had been added and the plant was thoroughly modern throughout. E. A. Wiltsee was manager of the property, which is owned by Eastern capitalists. As the ground is exceedingly rich it is expected that the mill will be re-built at an early date.

An official statement from the management of the Unity and Concord Mining companies of Webb City as to the production of the two properties during the twelve months closing December 31, shows that the year has been a good one. There has been a total tonnage of concentrate produced amounting to 5559 tons, or more than 11,000,000 lb. The two mines are owned by virtually the same people, including Phil Gray and associates of Webb City. The Concord mill is of 300 tons capacity and is situated in the south part of Carterville. It was completed last spring and was placed in operation in April. The production since that time has amounted to 3,294,880 lb. of zinc-blende and 782,000 lb. of lead. The Unity mine is situated in the Oronogo bottoms, north of Webb City, just north of the D., C. & E. property, and has been going steadily for the past year, the mill having been built in 1916. In size it is approximately the same as the Concord, but the production, due to the more extended operation, has amounted to 5,474,750 lb. of zinc concentrate and 1,649,430 lb. of lead. Both mines are sheet-ground properties, producing a high-grade concentrate and with ore that has been giving a good recovery for sheet-ground properties.

MONTANA

LEWIS AND CLARK COUNTY

(Special Correspondence.)—Severe cold has given place to warmer weather and the result is that more ore is moving from the various mines. The Helena mine in Grass Valley is sending out two carloads of silver-lead ore per week and there is a large tonnage in sight. A new skip with a capacity of two tons is being used. W. F. Word is general manager and consulting engineer. The shaft is to be deepened to 400 ft. before spring. The Cruse Consolidated and Rock Rose, adjoining claims, are sending ore to the smelter. In the Scratch Gravel hills four mines are shipping. The principal mines are the Thomas Cruse Developing Co. property and the Scratch Gravel Gold. The former is mining ore on the 600-ft. level and the latter is taking ore from the 300-ft. stopes. In Marysville camp the Barnes-King is working the Shannon and the Plegan-Gloster. The product is milled at Gloster. The returns from all of the mines worked by the Barnes-King are upward of \$100,000 per month. The Mt. Washington mine at Wickes is sending out two carloads of silver-lead ore to the smelter daily from the 800-ft. level.—A rich strike of silver ore has been made in the old camp of Elkhorn.—A discovery has been made recently in the Gould placers above Rimini. The vein was discovered by accident in excavating for a reser-

voir. The shaft is down 60 ft.; the ore assays 500 oz. in silver and \$100 in gold.

Helena, January 1.

OKLAHOMA

OTTAWA COUNTY

(Special by Telegram.)—The Miami district produced 155,081 tons of blende, valued at \$11,884,855, and 26,782 tons of lead ore, valued at \$2,960,000, in 1917.

Miami, January 5.

An excellent ore-cave has been discovered in sinking a shaft on the Blackhawk Lead & Zinc Mining Co. lease on the Walker land, south-east of Picher. The cave was struck at 228 ft. It is 10 ft. from the floor to the roof and the sides, roof, and

THE KOMSPELETZ REGION

bottom all are lined with crystallized lead and zinc ore. According to drill-holes put down on the lease a 30-ft. deposit of ore is apparent. The cuttings were said to assay around 18%. The orebody was found at 218 ft. and went down to 248 ft. J. Younts of Sikeston, Missouri, is president and Jack Williams of Miami, secretary and treasurer. R. C. Ulnier is the superintendent. The shaft already down will be used as a mill-shaft. A field shaft will be started at once on a nearby portion of the lease.

The Greening Mining & Smelting Co. is constructing a concentrator one mile south-east of Century. The Greening company is a subsidiary of the Hare Mining & Milling Co., which recently completed a big mill on a 20-acre lease near Picher. The officers of the two companies are: Alfred Hare, president and general manager; J. D. Carruthers, vice-president; W. F. Hearne, secretary; A. E. Fritsche, treasurer. W. M. Briten has charge of the construction of the new mill.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The underground force at the Red Hill Florence has been increased and preparations begun for vigorous developments on the 700-ft. level. Stations will be cut on the 600 and 700-ft. levels and drifts started from both points to seek the Florence vein. Several drifts and raises are advancing from the 500-ft. level to explore promising ground and to thoroughly develop the rich shoots lately opened by lessees.—An 18-in. vein of sulphide ore has been opened

on the 700-ft. level of the Silver Pick, and appears to be the same vein that has been developed on the 250-ft. level. At this point ore assaying \$6 to \$16 per ton in gold is exposed. The drift is advancing to seek the junction of two veins on the 250-ft. level. A drift and raise are being driven from the 500-ft. level, the raise intended to connect with the 250-ft. workings.—Splendid ore continues to develop in the Tonopah Divide mine in the Gold Mountain district, 38 miles south of Goldfield. At a depth of 450 ft. the vein is said to be 20 to 25 ft. wide, averaging \$15 to \$25 per ton in gold and silver.—On the 125-ft. level of the Butte Goldfield the vein has widened to two feet, assaying \$14 to \$16 per ton in gold. An accompanying 6-in. vein assays \$64 per ton. A station will be established at the 150-ft. point and drifts thrown out to develop the orebody. L. L. Patrick, of Goldfield, is president.—The Silvermines Corporation, operating at Hornsilver, is sending 150 tons of ore daily through the mill and reports an excellent extraction. The hoist will be replaced shortly by a hoist driven by a high-powered engine operated by compressed air. The company is preparing to use a 150-ft. cross-cut for storage of compressed air, sealing the cut with a concrete bulkhead. By this arrangement a single pipe will be used for charging the cross-cut and delivery of the compressed air to the equipment. As soon as the shaft attains a depth of 700 ft. a station will be cut and sinking continued to the water-level. S. E. Brady is manager.

Goldfield, January 6.

UTAH

UINTA COUNTY

The Crane Shale Oil Co. of Reno has purchased 200 acres of oil-shale deposits at Watson from New York and Salt Lake City owners for \$100,000. The deposit is said to have a depth of 80 ft. The shale will be treated by the new Crane process.

WASHINGTON

FERRY COUNTY

While engaged in the development of its property, the Virginia Mining Co., operating near Danville, has received \$27,000 net for ore shipped to smelters this year. The total output is 2000 tons. The ore of shipping grade is in a body 4 to 8 ft. wide on the foot-wall and 4 to 14 ft. wide on the hanging wall. One of these bodies is 150 ft. long. This is at a depth of 225 ft. Another level is expected to enter these orebodies at a depth of 500 ft. It will probably reach the objective within 60 days. The ore at 225 ft. contains $2\frac{1}{2}$ to 3% copper and \$18 to \$22 in gold per ton. Shipments have been proceeding at the rate of two carloads per week. The last two cars, composed of 44 to 50 tons, brought more than \$2000 after the deduction of freight and treatment charges. The property was acquired on a bond and lease for \$50,000, expiring in June 1920. The company has paid a royalty of \$2700, which is at the rate of 10%, and met the bond payment recently. It acquired an adjoining property for \$6000 this fall. Twelve men are employed. The number will be increased when the ground is opened on a broader scale. Buildings, ore-bins, and a compressor were erected this year. About 800 ft. of work has been performed in the lower adit.

CANADA

BRITISH COLUMBIA

The Granby Consolidated Mining, Smelting & Power Co. produced 2,886,489 lb. of copper in November. The Anyox plant produced 2,458,841 lb., and the Grand Forks plant 427,648 lb. of this quantity.

The production for November is about 75,000 lb. less than that for October and about 320,000 lb. less than November 1916. The reduction results from a lessened output from the Grand Forks plant, the output of Anyox in November having

been greater than in October. This is accepted as an indication that some of the changes at Anyox have been completed. Granby has adhered to its dividend rate of \$10 per annum; it has but 150,000 shares of issued capital and \$2,514,400 bonds due in 1928. Its quick assets on June 30 were \$5,219,000. At \$66 per share and par for the bonds, less the above quick assets, the whole Granby mine, smelter, converting, and power-plants are given a valuation of but \$7,500,000, or less by \$1,500,000 than the combined profits of the fiscal years of 1916 and 1917. At the annual meeting of Granby stockholders last October, it was stated that the operation of the contemplated coal and coke company was expected to effect a saving of possibly 50% in the cost of coke for the company's own requirements. The production of coal will probably exceed the quantity consumed by the company in its metal operations. The Grand Forks property has become less important as an operating factor for the Granby, as revealed in the constantly declining copper output from month to month. Last month's yield of less than 500,000 lb. was the smallest production recorded for over a year, barring the July total of 280,000 lb. At that time the property was in process of resumption after a two months' idleness caused by a strike.

The following amounts have been disbursed in dividends by some of the principal mines during 1917:

Con. M. & S.	\$ 996,503
Granby	1,499,848
Hedley	240,000
Le Roi No. 2.	29,199
Rambler-Cariboo	35,000
Standard	300,000
Utica	64,000
Total	\$3,164,550

Increase of the capitalization of the Lucky Jim zinc mines to 6,000,000 shares from 2,500,000, par value \$1 each, is proposed in a special resolution to be presented to the stockholders at a general meeting to be held at Victoria, January 12. The increase will enable the company to absorb \$125,000 in bonds, discharge other obligations, and provide a surplus of treasury stock for the improvement of the property, it is stated in a circular issued by Walter J. Nicholls, secretary.

One of the best strikes of recent years in the Slocan district has been made on the Hidden Treasure claim of the Noonday Mines Co., according to a report from Kaslo. More than seven feet of ore has been exposed at a depth of 400 ft. A foot of the body has an average content of \$7000 to \$8000 net to the carload of 30 tons with silver at 86c. Ore from the same vein, lost 15 years ago, yielded \$5000 net to the carload when the price of silver was in the neighborhood of 55c. The Hidden Treasure adjoins the Richmond-Eureka of the Consolidated Mining & Smelting Co. which is credited with a yield of \$1,500,000 in ore taken from a shoot of this kind. Search for ore in the Hidden Treasure began many years ago, and when found it disappeared after producing about \$40,000 worth of ore. The search was renewed by the Noonday company two years ago. Working on another theory Bruce White, manager, sought the body in a different section than that explored by the pioneers. He operated steadily, although with a struggle at times, removed \$16,000 in the course of the investigation, and had no indebtedness when the ore was struck several weeks ago. The shoot has been followed 30 ft. The milling ore is of a superior quality; it contains lead and silver and little zinc. This ore will be concentrated in the mill of the Slocan Star if arrangements can be made with that corporation. The properties are on the opposite sides of the same hill, and their workings are so situated that the removal of Noonday ore can be done with economy through the Slocan Star mine. The course and situation of the body suggests that it may be found in the Slocan Star.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

DONALD F. IRVIN is at Antofagasta, Chile.
JOSEPH IRVING is at Hurley, New Mexico.
W. G. SWART, of Duluth, is at New York.
D'ARCY WEATHERBE writes from Shanghai.
VICTOR RAKOWSKY, of Joplin, is at Washington.
H. R. BARKS is Lieutenant in the Canadian Engineers.
E. D. McDERMOTT has returned to London from Siberia.
RENSELAER H. TOLL has returned to Berkeley from Arizona.
R. A. VARDEN has returned to England from Western Australia.

H. H. NICHOLSON is in the Saline Lake district of north-west Nebraska.

M. E. MACDONALD has returned to Los Angeles from Zacatecas, Mexico.

J. B. TYRRELL has been nominated for the presidency of the Canadian Mining Institute.

J. MORGAN CLEMENTS passed through San Francisco on his return from China to New York.

R. S. BURETTE is Captain in the Ordnance Reserve Corps and is stationed at Washington.

ROBERT S. LEWIS passed through San Francisco on his return from Palo Alto to Salt Lake City.

L. D. RICKETTS leaves Santa Barbara on the 12th inst. to make a tour of inspection in Arizona.

M. R. HULL, mechanical engineer to the Sissert company in Russia, has returned to New York.

H. C. DUDLEY has been appointed Captain in the 36th Regiment of Engineers and has closed his office at Duluth.

ARTHUR P. WATT has resigned as metallurgist to the Missouri Metals Corporation and opened offices as consultant at 52 Vanderbilt Ave., New York.

ARTHUR J. HOSKIN has resigned as editor of 'The Mining American,' and has resumed professional practice at 717 Cooper Bldg., Denver.

F. W. TRAPITGEN, formerly professor of metallurgy in the Colorado School of Mines, is now professor in the Dakota School of Mines.

B. MAGNUS has been visiting the zinc and lead plants of the American Metal Co. in Oklahoma and Colorado for the past month, and will visit smelters in Utah, California, Canada, and Montana this month, returning to New York early in February.

R. L. CHASE, of Edwin E. Chase & Son, Denver, has prepared a mining and geological map of Colorado that can be recommended to engineers, especially those coming to Colorado from the outside. The map is compact, 21 by 29 inches; it portrays the geologic structure in vivid colors and in a broad way, omitting subdivisions of geologic periods. The coloring is done by hand. Price \$3.50. For sale by Mr. Chase at 1028 First National Bank Bldg., Denver.

Obituary

WILLIAM HAGUE, Lieutenant in the 116th Regiment of Engineers, died of bronchial pneumonia on January 3 in France. He graduated from Harvard in 1904 and therefore was about 35 years old. The only son of the late James D. Hague, he followed worthily in his distinguished father's footsteps and had already given more than a promise of being an unusually capable and useful man. As soon as war was declared he volunteered for active service and went to the training camp, resigning his position as managing director for the North Star Mines company at Grass Valley. A man of high character and

fine ideals, we record his untimely death with infinite regret, tempered by the recognition of the fact that he gave his life to the supreme call of manhood. He leaves a wife and little son.

Prices of Chemicals at the End of 1917

Acetate of lead, brown, per lb.	15½—16 c.
Acetate of lead, white cryst., per lb.	16½—17½c.
Acetate of lime, per 100 lb.	\$6.00—6.05

The Joplin lead-ore market has shown greater strength and the purchases made have been extremely heavy, reaching such proportions as to absorb practically two-thirds of the surplus stock now held in the district. While all of this surplus is not moved, it is believed that now the lead surplus has been reduced to 2000 to 2500 tons on hand. With the present conditions of the roads it is not believed that all purchases will be loaded out under 15 to 30 days. The base price for the major portion of the ores sold is \$75 per ton.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

A committee has been appointed by the South Western Mining Safety and Sanitation Association of Webb City, Missouri, to investigate the possibilities of substituting spelter for copper, tin, and other metals for various purposes. Movements are on foot to interest capital in the building of a zinc-rolling mill. The price of sheet zinc has been for a long time ruling at much higher than the normal cost of producing sheet zinc, on account of there being only two producers of this material. It is believed that the use of sheet zinc could be enormously increased if the price of the sheet metal were more moderate.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Samuel Montagu & Co. says: An advance specimen of the one rupee note has been received in India from the India Office in London. The note measures five inches by three and a half inches, and has an engraving of the head of the King Emperor in the left-hand top corner, similar to that on the silver rupee. There is a pink medallion in the centre of the note, across which the phrase "One Rupee" is printed, while the numeral "1" is printed in opposite corners so as to facilitate counting. The Indian mints have been engaged in turning out munitons for the supply and transport corps and other divisions; the advantage, therefore, of lessening their duties, by the issue of small notes instead of coins, is obvious. Notwithstanding their special activities in munitons, the mints turned out in 1916-17 Rs. 207,737,326 in silver coin, as against Rs. 16,292,199 in the previous year.

Mining companies are requested to advise us of new dividends declared and to furnish complete figures for dividend disbursements made during the year 1917, in order that our monthly dividend-list may be kept up to date.

Eastern Metal Market

January 2.

The markets are all decidedly quiet as the new year begins. The last week in the old year has been probably the quietest of all, as is usually the case.

Copper at controlled prices is moderately active.

Tin continues alarmingly scarce, and high, at nominal prices.

Lead is dull but firm.

Zinc has a better tone but is inactive.

Antimony is quiet.

In the steel trade the announcement has been made by the President that the present schedule of fixed prices will continue in effect three months longer, and that an agreement has been entered into whereby, on contracts made in the coming three months, prices would be revised in deliveries after April 1, 1918, to conform to any changes that might become effective on that date. Possibly 100,000 cars may be ordered for its railroads by the Government, now that it has taken control of them. Additions to the steel capacity of the country in 1917 were larger than expected. There were 97 new open-hearth furnaces completed in 1917, with an estimated capacity for producing 4,326,500 gross tons of steel ingots. The Steel Corporation furnished 1,220,000 tons of this total. The increase in 1917 was 4,205,000 tons, so that 1917 constitutes a record. New blast-furnaces blown in during 1917 were 14, with an annual capacity of 2,520,000 tons, against only five new furnaces in 1916. Sixteen more are now under construction.

COPPER

The copper market begins a new year in a decidedly stabilized and apparently comfortable and satisfactory condition. This has been true for some time, and is due to Government regulation of prices and distribution. It is apparently a settled fact that there will be no change in prices for a considerable period; at least no reduction will be made, and the trade feels that it can proceed safely and freely for a while. Sales are being made regularly to the trade, with Government and Allied needs having the priority at the established price of 23.50c. per lb. for carload lots or more, and at 24.67½c. for less than carloads and for delivery in the first quarter. Many in the trade have reason to believe that the supply of copper will be sufficient to cover all reasonable needs. It is also stated that the producers have on their books orders for the Government's requirements for the next six months. The fuel question may result in some lessening of activity among consumers using copper for non-essential purposes, but this may not prove a big factor in lessening consumption. December exports seem likely to have been larger than the November, which were 38,638 gross tons. The total for 1917 to December 1 was 448,596 tons, against 327,310 tons for the whole of 1916. The monthly exports have been 40,781 tons to December 1. For several months the London market has been unchanged at £125 per ton for spot electrolytic.

TIN

Tin of all grades continues scarce, and the market, as the new year enters, is nominally higher than at any time in its history. In this district it is nominal at 85 to 86c., New York, for spot Straits with other grades correspondingly high. No metal is being offered for spot delivery except a little Banca tin at about 84c. The British government has apparently taken some important action, the details of which are lacking so far. It appears probable that all speculation in the metal has been forbidden and that sales in that country will be permitted only for consumers' requirements. It also probably means that the American consumers' names will not have to be

passed upon by the London Tin Committee, leaving consumption entirely to the American Iron and Steel Institute. It is probable that the result of this action will be to insure more adequate supplies to this country, as well as the elimination of permits with their difficulties and delays. Arrivals of tin to December 27 were 1705 tons, with 4400 tons afloat. The last cable from England, on December 28, showed spot Straits at £295 per ton, which compares with £309 10s. on December 21, a decline of £13 10s.

LEAD

The firmness which has characterized the lead market for many weeks still rules as the new year opens, and prices are at unchanged levels. The quotation for early delivery in the outside market is 6.50c., New York, or 6.35c., St. Louis, with the leading interest asking 6.25c., New York. The market is only moderately active, with a fair-sized demand during the past week for lots varying from carloads to 100 tons. There seems to be no trading in large volume. The industry was free from price-fixing in 1917, but it will be imposed in 1918 if a runaway market develops, of which there seems little prospect now. A lesson in this was learned in 1917. The preliminary estimate of the 1917 lead output by the U. S. Geological Survey is expected soon, and it is awaited with interest. Some put the total at 625,000 tons, against 571,134 tons in 1916 and 550,055 tons in 1915. The output in the first half of 1917 was 306,062 tons and it has probably been heavier in the last half.

ZINC

A slightly better tone pervades the market at the beginning of the new year but the market is practically at a standstill, with no desire by buyers to buy nor by sellers to sell. The cause of these conditions is probably the high bids on the Navy's 1000 tons of grade C zinc, and the probably similar bids on the 4000 tons of the same material for the Army, though these are not known as yet. It is stated that only a few producers offered bids on the latter order. It is felt also that this fairly large interest in the market on the part of the Government is a forerunner of more buying of other grades. Irregularity as to quotations on prime Western for early delivery characterizes the situation. Some ask as high as 8c., St. Louis, but the market is probably quotable at 7.62½c., St. Louis, or 7.87½c., New York, at which a few small sales have been made. The year 1917 has not been altogether an unsatisfactory one, and the new year begins with prices only a little above the lowest level of 1917.

ANTIMONY

Late last week a consumer made inquiry for a fairly large amount for prompt delivery, on which later it is understood some fairly low quotations were made. The prices are therefore easier at 14.50 to 14.75c. per lb., New York, duty paid, for Chinese and Japanese grades for prompt delivery. War demand is more uncertain than ever for our own needs in particular.

ALUMINUM

There is no interest in aluminum and No. 1 virgin metal, 98 to 99% pure, is unchanged at 36 to 38c. per lb., New York, for early delivery.

ORES

Tungsten: There is very little news. The market continues strong after the demand noted last week with 60% concentrates selling at \$24.50 per unit for wolframite, and \$26 per unit for scheelite. Ferro-tungsten is quiet at unchanged prices.

Abbreviations: g = gold, s = silver, c = copper, l = lead, z = zinc.

Notes: Companies not included in the above list are requested to submit details. Changes in capitalization and new dividends will be entered on a receipt of the information. *In current year additional dividend in stock, \$2,000,239.

THE 116th meeting of the Institute will be held at New York from February 18 to 21 inclusive. An interesting programme has been arranged.

GOLD production decreased in 1917. The Mint and the Geological Survey estimate the American output at \$84,456,600, which is \$8,130,000 less than in 1916 and the smallest total since 1904, when it was \$80,464,700. The rest of the world is not likely to have compensated for this decline, but statistics are not yet available.

KEEN satisfaction has been expressed by the oilmen of California at the appointment of Mr. Mark L. Requa as head of the oil division of the Food Administration. He is to direct operations on the oilfields under Government control. Mr. Requa has had experience in the oil business and is thoroughly fitted for the task. We join with the mining profession in commending the appointment.

CARRANZA is said to be offering Clipperton island for sale to Japan. The Señor is usually more astute than that. He overlooks the fact that Viscount Ishii recently visited this country and obtained recognition of what the Japanese papers call "the Monroe Doctrine of the East." That balances a counter courtesy on the part of Japan, which means that the market for American islands is limited. If Mexico has any land for sale she had better call at Uncle Sam's real estate bureau.

OUR contemporary in London, 'The Mining Magazine,' is 'carrying on' with manifest vigor, despite the many hindrances due to the War. The issue for December, just to hand, is excellent, particularly in respect of the engineering drawings that accompany the article by Mr. J. Waring Partington, on the Taylor concentrator at the East Pool mine in Cornwall. Our compliments to Mr. Edward Walker and to Mr. W. F. White, the editor and managing director respectively.

AMERICA'S foreign commerce in 1917 amounted to \$9,050,000,000, of which three billions only represented imports. In the last three years our foreign commerce has reached a total of \$22,201,077,067, with an ac-

cumulated credit balance in our favor of \$8,115,883,677, which is about equal to the total stock of gold in the world. In addition to this trade balance the United States government received authority from Congress to advance something over four billions of dollars to our Allies out of the war appropriation of 19 billions.

WHAT happens to a successful trade paper is illustrated by our friend the 'Iron Age,' whose first issue in January consists of 130 pages of reading matter and 718 pages of advertisements. The magazine is two inches thick and weighs 5½ pounds, the postage on which is 5½ cents and the cost of paper alone must be 27½ cents. It is a comprehensive directory of the iron and steel trade. The front cover carries a beautiful steel engraving, by the American Bank Note Company, whose handiwork on U. S. currency is so attractive to most of us.

ON another page we reproduce a contract offered by the Minerals Separation company for signature to a metallurgist that had invented an improvement in flotation. The text speaks for itself. Like the contract that the Minerals Separation people attempted to force upon metallurgists employed by their licensees, this is a rank bluff and an imposition upon the self-respect of a technical man. It will be noted that Minerals Separation consents to the use of apparatus by its licensees, and the inventor is to pay 10% of the selling price of the machine to Minerals Separation, and as against the privilege of paying 10%, the inventor is not allowed to sell his machine to anybody not licensed by Minerals Separation, on penalty of a fine of \$10,000. It is to laugh! Fortunately, that is what the inventor did, sharing his sense of humor with us and our readers.

THE passing of Thomas L. Livermore removes a distinguished figure from the mining world. He was long the associate of Alexander Agassiz and Quincy A. Shaw, and was responsible for the general direction of America's most remarkable copper mine, the Calumet & Hecla. His force of character, and his exact and scrupulous observance of business propriety, made him a factor in the copper market and enabled him to throw his weight against the policies that at one time tended

strongly in the direction of large combinations to control the output of that metal. Colonel Livermore, acting in accord with his associates, held to the advantage of independence, thereby encouraging other important copper companies to resist the temptation toward amalgamation and restraint of trade. It is noteworthy that, of all the leading non-ferrous metals, copper has been most nearly free from pernicious capitalistic control. A contrary disposition on the part of Colonel Livermore might have altered completely the character of the copper industry, to the detriment of this country and of the world.

PROTESTS are being made by the American Mining Congress in behalf of the mining industry against the proposal to place the direct control of mining operations in the hands of the Government. Mr. M. D. Foster, of Illinois, chairman of the Committee on Mines and Mining, has introduced a bill providing for the control of mineral deposits by the President, similar to that provided for food and coal in the Food Act. This bill seeks to appropriate \$150,000,000 for the purpose stated. The idea, it is said, is "to ensure an adequate and continuous supply of certain rare metals, such as tungsten, which are needed for war purposes." Surely such legislation is wholly unnecessary. Statistics demonstrate that the operators of mines are responding whole-heartedly to the call for the metals needed for munitions, and if further increase of production be necessary it can be effected by the assistance of the Bureau of Mines, the Geological Survey, and other agencies that exist to aid the mineral industry of the country. The first result of such an enactment would be to place a \$1 halo on a number of prominent millionaires and cripple the industry with unnecessary red tape. Let the President say what metals are needed and they will be forthcoming, for the mining industry can furnish both the money and the men to do it without further legislation or the creation of more committees.

GERMANY had planned before the War to violate all manner of anti-trust principles and national prejudices throughout the world. We present demonstration of the Teutonic performance on another page. It resembles a spider's web, and was alluring as a market into which all were invited in language recalling the nursery jingle "Will you walk into my parlor"? Moreover, the unsuspecting world did walk in, and through this astonishing combination it became possible for Germany to absorb metallic products in preparation for war without exciting suspicion. Many reputable houses in the system were wholly unconscious of the use being made of them in furtherance of the gigantic plan for Germanic imperial dominance. They were found in a strong position in the world's markets, and it was deemed easier to absorb the advantage of that position by letting such firms make money in association with a German house whose distant 'metallbank' was invisible. The British are now thoroughly awake to the peril of again permitting such trade organizations as those created for

the ultimate purpose of the Prussian machine, a purpose that we live to see frustrated. Apart from the national question it is clearly dangerous to permit any group in any country to control the metal market of the world to such an extent.

COMPARISON of metal prices during 1917 as against 1916 shows that the industry had good fortune:

	1917	1916
	Cents per pound	Cents per pound
Copper	27.52	28.03
Lead	9.06	6.88
Zinc	9.18	13.70
Tin	61.56	43.26
Silver	81.23	65.66
Mercury per flask.....	106.33	126.89

The fixation of the price of copper at 23½ cents pulled down the average for the year, but not to a calamitous degree, owing to the higher prices ruling during the first eight months. The beginning of 1918 sees copper pegged again at 23½ cents, for word has come from Washington that the Federal authorities have continued the same price for another four months. The collapse of the spelter market has been the most untoward event of the year. Zinc is firm at 7.87 cents, which, however, represents a decided recession even from the 1917 average. The average price of lead in 1917 was being paid in September, but since then the decline has been serious, falling to 6½ cents during the closing quarter and beginning the new year at about that figure. We produce so little tin in this country that the price affects not the miner but the manufacturer, who has to import it. The silver market is strong at about 9 cents above the average for 1917 and the prospect is good for a slightly higher price when the proposed fixation has been consummated. Mercury is an important product of California, and it is pleasant to record a present price that is \$24 per flask higher than the 1917 average. All that the miner can ask for 1918 is that the prices for copper, silver, and mercury may be maintained, and that those for lead and zinc should be raised a little, the prices of the latter being good as compared with the pre-war period but the increased cost of operation offsets the apparent advantage. On the whole, the mining industry is not suffering from the War.

Wildcats

The *felis rufus* of mining finance is an interesting animal, not only on account of the ravages he causes in well-lined pockets, but by reason of his variable temperament. He is not always predatory. The dictionary says that he is the expression of reckless or unsound finance. One definition says: "Originated or characterized by wild irresponsible speculation; unreliable or unsafe, by reason of reckless financiering." A nefarious motive is commonly assumed to be at the back of a feline project. In 'Yavapai,' a paper published at Prescott, we read the following comprehensive definition. "A wildeat mining company is one in which the management raises money,

often by exaggerated and misleading statements, intending to use the funds so raised for their personal profit, rather than for the development of the property, and without regard to securing an adequate return to investors." "Their profit" must refer to the organizers of the company, and "investors" is a euphemism for 'speculators.' Still it is a definition that would be generally acceptable. However, malign intent is not a necessary characteristic of the 'wildcat,' for that term is now used sometimes simply to indicate a long shot, the locating of claims far from points of actual discovery, the taking of a sportive risk in mining. We remember being threatened with a libel suit because we said that the Great Boulder Proprietary mine, in Western Australia, started life as a wildcat. To the lawyer that called upon us we explained how 'wildcat' was used in Nevada as a term for riskiness in which deception was not involved. We were reminded of the senator from Nevada who used an epithet that, according to Owen Wister in 'The Virginian,' must be accompanied by a smile lest it start gun-play; how a committee of senators was appointed to inquire into the scandalous incident; and how the colleague of the senator from Nevada testified that this opprobrious epithet, reflecting harshly upon another gentleman's pedigree, was used as a term of endearment at Virginia City; indeed, when a denizen of the Comstock returned from the Coast he was accosted with a slap on the shoulder and the polite inquiry, "How are you old — of a —!" *Se non è vero, è ben trovato.* That is what the English lawyer said when I tried to persuade him that 'wildcat' was almost a term of financial endearment. So, to avoid confusion and prevent imposition, as they say at Niagara Falls, it may be well to adopt a definition more like that of our contemporary at Prescott. He, of course, cocked an eye at Jerome, where wildcats breed like rabbits. If you apply the epithet 'wildcat' to any of the numerous enterprises having names that entwine the words, Great, Copper, Jerome, Verde, United, and Extension into a halo of romantic expectation, you will be asked indignantly if the United Verde Extension was not a 'wildcat' until it was proved a rich mine? Was it? It was a risky venture, without question; but it was a sane one, in which the amount of money risked was not disproportionate to the possible winning. Moreover, the men that subscribed the working-capital were able to lose their money without going bankrupt; they risked no more than they could afford to lose. The venture was started by an intelligent and experienced engineer, who paid for special geological advice and proceeded to explore in a scientific way. Even the earlier efforts, before Messrs. Douglas and Tener took the prospect in hand, were conducted intelligently; they were based on legitimate inferences and their organizers made no attempt to collect money "for their personal profit"; the money they raised was spent by experienced men in a systematic search for ore and in a locality in which ore was likely to be found. It may be said that this is wisdom after the event, and indeed the character of a wildcat can best be determined by its performance, for

the motives behind human actions are difficult to prove. Unanimity of opinion concerning the various prospecting enterprises fostered by the astonishing success of the U. V. X. is not to be expected. A few are obviously legitimate ventures, a few are equally obviously hopeless, if not nefarious, but the larger number cannot be labeled with certainty. Those prospecting below the big fault at Jerome have a reasonable chance, but, if we may venture the opinion, those above are unlikely birds, as unlikely as a volant non-ruminating artiodactyle. The absence of evidence of ore is used by some of these almost as a favorable argument: "Look at the U. V. X." they say, "that had no ore to start with." They ignore the geologic structure and pin their faith on the happening of a miracle. That is not mining, that is 'wildcatting.'

More Competency Needed

The Government 'nitrate plant' at Muscle Shoals, Alabama, will begin producing fixed nitrogen from the air in the coming month of July. This affords a sense of heightened security. At the same time it should cause the public to reflect that the same officials that allowed themselves to be bamboozled by a group of talkative chemists and electricians, still remain in control at Washington and are responsible for duties in the serious business of getting this nation ready for war. Less than two months ago, nearly a year and a half after Congress had appropriated the funds necessary for building a great factory to make nitrogen products, a commission of engineers visited Muscle Shoals and made the final recommendations that construction be started at once. Perhaps the plant will be ready in six months, though we incline to doubt it. That would be quick work, which is one reason, though not an altogether defensible reason, for scepticism. One thing that intensifies the feeling of uncertainty is a rumor, which wandered over the wires and got into print in the newspapers, to the effect that the plant erected by the American Cyanamid Company at Sheffield, Alabama, was nearly ready and would soon be supplying the needs of the Government. In this confusion of the facts the public is sure to gain a wrong impression. Those in authority may claim that a manufacturing establishment is in fact "nearly ready," although it has just been started, when its completion is due in six months, but it is not stating the facts with proper regard to their true time relations, to put it as mildly as possible. Furthermore, this association of the name of the American Cyanamid Company with the matter obscures the issue. Either this is a democracy or it is not; if it is, then let us run the risks incident to democracies by confiding the truth to the people. The public, in a democracy, will learn the truth sooner or later, and if later the postponement will engender a lack of confidence that is like pouring sand into the bearings of a dynamo. We understand that the Government, after realizing that it confronted the peril of having no adequate and safe supply of nitrogen products available,

because it had been influenced by men who counseled delay under the guise of experimentation, and thereby served the cause of the Hohenzollern dynasty, suddenly decided to build a big plant, and selected a site that is above reproach. It is situated far in the interior; it is capable of easy protection from a military standpoint; and it has at command, from the rapids in the Tennessee river, a minimum of 680,000 horse-power, which can be developed. The American Cyanamid Company then came to the rescue with a corps of engineers possessing superior knowledge of the details needed for the enterprise. Their accumulated experience, their well-trained technical staff, their working drawings, all have been placed patriotically at the service of the Government. This corporation, therefore, stands among those to whom the country owes special gratitude. On the other hand, it is important to note that the water development cannot possibly be completed within another year, and that it is necessary to fall back upon 30,000 horse-power obtainable from the Alabama Power Company, and that an auxiliary 30,000 horse-power steam-plant will also be erected at the foot of the great shoals over which 23 times as much energy glides unharnessed and unused, and all this because there was no one in authority whose wisdom and judgment and sense of duty were large enough to protect the interests of the American people. It is no light matter to co-ordinate the many activities needful to urge forward our preparation effectively. We do not wonder that men fail in the attempt. We are not surprised at confusion of authority nor at some clogging of the wheels of administration. It takes time to find the men that can efficiently carry the vital responsibilities of war. France swept out ministry after ministry before Clemenceau was called to establish a government in which confidence could be reposed; England floundered through much impressive speech-making to the vigorous activity of Lloyd George. Meanwhile we still have Daniels and Baker and some others who might at least remove the doubt as to their superiority by giving someone else a chance to do better or worse. General Pershing has been swift to fit new human metal into his fighting machine in France in an effort to improve the service. It is an instructive object lesson. Incompetence will not do on the firing line. What then of incompetence behind the firing line? The world takes it as a matter of course that there is efficiency in Germany, while in our own country even the man on the street gossips of incompetence. Such a reproach upon American intelligence must be effaced, and one essential is to cease being tolerant toward officials and committees that are not achieving the results for which they were put in power. The action of President Wilson in taking control of the railway system was a display of firmness and decision that may mark a salutary change in our methods. It would seem that many of the war committees need to be re-constituted on a basis more consistent with democratic principles. The public has reason to distrust the disinterestedness of committees when composed of men who are the chief producers of the materials over which they hold authority for

the Government. The metal-market has been embarrassed for months at a time by failure to declare firm policies that looked far enough into the future to admit of consistent plans for steady and economical production. For example, stagnation has afflicted the zinc industry because the prices have not been fixed and no indication has been given as to the probable requirements of the Government. Experience gained from the foreign demand before we entered the War led to expectations that created extraordinary expansion of zinc mining, and now the industry is almost paralyzed, while a number of properties are maintained in readiness for active operation merely in the hope of an early decision by the Government. Such methods are wasteful of men and money, and in the end leave us crippled when the output of the mines is urgently needed. The Department of Agriculture has been justly criticized for policies that place obstacles in the way of increased food production. On account of the extraordinary demand for sulphuric acid to make munitions a shortage of fertilizers exists, but no organized effort has been made to conserve the wasted materials that should be utilized in 'compost heaps', nor to encourage efforts to improve the soil without the use of super-phosphate, where that is insufficient. Government financial aid is urgently needed to develop additional sulphuric-acid plants in the West where advantage might be taken of the vast deposits of phosphate rock that now remain unworked. Furthermore, the plan to bring under cultivation the great area of 'cut-over' lands in the Middle-West and South, in order to obtain the benefit of virgin soils, at a time when fertilizers are scarce, actually has been discouraged by the Department. President Wilbur of Stanford University says that the American people have not wakened to the reality of the War, but the time has come when they must rouse themselves. They must realize that the committee that fails to organize industry, the official that retards the output of the necessities of life, the man that temporizes or exalts his selfish interest above that of the common good, all these are giving aid to the enemy, and must no longer be suffered to stand in the way of effective prosecution of the business of preserving our republic. The country possesses an abundance of men able to take the places of any incompetents and force the work with energy. The spirit that should prevail was well expressed in the advice given by a committee of the Senate to Secretary Baker the other day when he was told to cut red tape and order the commanders at the military camps to buy clothing for the soldiers in the nearest market. By request of the President this advice has been converted into a slogan for all the Departments at Washington. The object must be to do the things that need to be done and to do them swiftly, if we are to win. Efficiency is excellent, but, after all, efficiency is mechanical perfection and involves routine that takes time to develop. There is something superior to efficiency, something for which free America has been conspicuous in the past, and in which she has not yet lost her cunning. That thing is competency, which is the ability to do things with power.

DISCUSSION

The Rusting of Iron

The Editor:

Sir—The article in the MINING AND SCIENTIFIC PRESS for December 8, 1917, on the above subject, contains the following statement regarding the Bureau of Mines: "The Bureau rejects the electrolytic theory that has been so universally accepted, on the ground that pure iron, that is to say, the purest iron obtainable, rusts and pits as badly, and often worse, than the impure product." What the Bureau says in its 1916 Year Book is that "many of the actual facts observed . . . are not satisfactorily accounted for by the usual interpretation of the electrolytic theory." There is, in reality, nothing in the electrolytic theory which does not square with "actual facts observed," and the only trouble is with the "usual interpretation" of the theory. Exponents of the electrolytic theory have never claimed that pure iron does not rust, but many manufacturers of pure iron have gone too far in claiming immunity to corrosion for their product on account of its high purity, forgetting that different polarity, causing electrolytic action, may also be caused by distortion or unevenly stressed parts in the metal and by accumulations of rust or dirt on its surface. These factors are, indeed, quite as important in promoting corrosion as impurities contained in the metal itself, and this is entirely in accord with the electrolytic theory, albeit not with the usual interpretation thereof. By pure iron is understood certain products of the open-hearth processes which are marketed today and which should more properly be called pure steel, for they lack both the graphite contained in cast-iron and the slag contained in genuine wrought-iron. Cast-iron and wrought-iron are very durable products, in spite of the large proportion of graphite and slag that are incorporated in the pure iron, but one should not be misled into construing this as a contradiction of the electrolytic theory, for it is apparent that both the graphite and the slag, being in themselves practically non-corrodible substances, must, on account of their fine distribution, protect the underlying iron from corrosion. This protection must increase as more and more of the slag and graphite respectively becomes exposed by corrosion, so that there will be a marked slowing of the corrosive effects after years of service. A mistake often made is to put commercial wrought-iron under the term 'pure iron'; while it is pure in a chemical sense, it is equally certain that it contains from 5 to 6% of slag mechanically mixed with the iron, and, in my opinion,

it is this very slag that gives it the characteristics that distinguish it from pure steel, namely, a tough fibrous structure, tremendous resistance to vibration and repeated stresses, and a high factor of immunity to corrosion.

N. BOWLAND.

Pittsburgh, Pa., December 18, 1917.

Recruiting Labor From Gold Mines

The Editor:

Sir—S. E. Rau-Roesler's argument concerning the ethics of certain engineers and the reflections thereof on the profession in general, has aroused deep interest on my part, and has brought to mind ideas embracing the interrogative: Would it be consistent for a man, whether engineer, metallurgist, or miner, to refuse the acceptance of what he considered a better opportunity if such should present itself? In fact, do we not all encourage such a system by even so small a thing as a business card, and by our earnest endeavors to produce results? Our stock in trade is our brains and labor which we sell or lease to the highest bidder if said bidder is financially able to cover his bid, as we must figure on covering the initial plant, our brains, together with depreciation at an early date in life. Allow me to suggest in this connection a method of combating the Inspiration system of procuring labor. Would it not be much better to visit with the miners whom Mr. Arnold had employed, wish them good luck, a pleasant journey, and incidentally mention that your company stood ready to pay their return fare and that of any other good men they could secure while working for the Inspiration, at the same time sticking up some posters showing the miner's wage at each camp, the methods of working men, the living conditions, and general surroundings. With the balance in favor of the garden, I am sure such a procedure would bring results.

J. WARRINGTON STOCKHAM.

Eureka, Utah, November 26, 1917.

The Need for Gold

The Editor:

Sir—Under your issue of December 1, I notice an article on this subject by Lester S. Grant. I would like to make a few comments on same, though they are rather rusty, as I have not been in South America since 1910 and 1911, where I came in contact with a good many drummers from various parts of North America and

Europe, who were selling goods payable in Peruvian soles, which is a facsimile of the English pound sterling, the only Government in South America that has prohibited the issue of paper money.

In the larger cities of Chile, to wit, Valparaiso and Santiago, landlords some fifteen years previously rented their premises at approximately \$300 per store, payable in Chilean money, which at that time, if my memory is correct, had depreciated to about 25c. on the dollar, the depreciation of which bankrupted a great many landlords; in both Chile and Argentina, where paper money is exclusively used (paper money in Chile being worth then about 25c. on the dollar and in Argentina about 50c. on the dollar) there being no gold in circulation, restaurants omitted from their bills of fare the price of ham and eggs and everything else, and the price paid was the quotation of paper money at its value for that day.

As Mr. Grant says, we may have a gold and silver stock sufficient for what we think is necessary for this year and possibly the next, but if gold is smuggled out of our country, as it has been in South American countries, with the exception of Peru, our paper money will have no more value than Confederate money, which was backed by no gold reserve at all. Without a plentiful supply of gold and silver our paper money is worth no more than yesterday's newspapers which kindle to-morrow's fires.

FRED S. ROWAN.

Independence, California, December 20, 1917.

Oil in Flotation

The Editor:

Sir—I have read with interest statements by yourself and by others that oil was not necessary for floating mineral particles, yet so far as I have read no one has stated what these reagents are or what results were obtained by their use. In a recent issue of your paper, Mr. Schwarz states that he is successfully floating lead from zinc, making nearly as complete a separation as that of any other mineral floated from its gangue, yet he neither states what reagents he uses nor the results. I am treating a high-grade lead-zinc ore, and the best results I have obtained are about 50% lead and 24% zinc by the use of eucalyptus oil. The feed is about 3% lead and 20% zinc; after selective flotation of lead and flotation of zinc, the tailing contains trace of lead and under 2% zinc. Will some of your writers kindly give figures of their results on the selective flotation of lead?

MILLMAN.

Los Angeles, December 29, 1917.

[We have referred editorially more than once to the use of nitro-naphthalene and alpha-naphthylamine, patented by H. P. Corliss, as a frothing-agent instead of oil. Naphthalene is the moth-ball of commerce. Both the above-mentioned reagents are derivatives from naphthalene, which, in turn, is the creosote fraction from the

distillation of coal-tar, itself a by-product of the coke-oven. The naphthalene is nitrated with nitric acid, the resulting alpha nitro-naphthalene is then treated with hydrochloric acid and iron shaving, which reduces the nitro-compound to the amine derivative, producing the alpha naphthylamine, which is the frothing-agent— $C_{10}H_7NH_2$ —used in flotation. Its solubility is in the ratio of 1000:1 in cold water and 600:1 at 50° C. From $\frac{1}{3}$ to $\frac{1}{2}$ pound per ton of ore suffices to produce a highly efficient froth. In regard to the selective flotation of lead, our correspondent is referred to the chapter on 'Differential Flotation' by O. C. Ralston in the book entitled 'Flotation', published recently.—EDITOR.]

Misfires

The Editor:

Sir—In reply to Mr. Harrington's article on misfires, in the December 1 issue of your paper, will say that if proper care is given to trimming the fuse-end that is used for the cap, a large percentage of misses will be avoided. I have been employed at the Tamarack mine, at this place, where there has been considerable trouble with misses; the miners say it is the caps, others say the fuse; I found it was a dull knife used and fuse cut square across; also carelessness in inserting the fuse into the cap. I have taken caps where the fuse had burned to the cap and cut new fuse properly and exploded the cap. I have noticed that the man who makes the primers generally tries to see how fast he can work, and cuts his fuse with a dull instrument square across, and nearly always there is a little gutta percha drawn across the powder; he then forces the cap on, and crimps; the result is a few misses. When I want to be sure of my round, I try to cut my fuse with a sharp knife diagonal with the fuse, make a clean cut, and when inserted in the cap I see that it does not jam but goes in free—do not crowd it hard against the powder, then crimp. For wet holes let him use P & B paint. You can crimp your cap on ever so well, but if you don't cut your fuse right and with care you must expect misses. Let your contributor try my scheme, and I am sure he will get results, as I have used this method where others fail. If he gets results from my method, then I will feel re-paid for this letter.

HENRY HOARD.

Sunset, Idaho, December 12, 1917.

[Our correspondent has hit upon a probable cause of the trouble mentioned by Mr. Harrington. We had previously made a similar suggestion in an editorial article entitled 'Blasting Troubles' in our issue of December 8. We called attention to the pinching of the fuse in cutting with a defective instrument of the type commonly supplied in which a fuse-cutter and crimper are combined in the same tool. The dull knife, as Mr. Hoard points out, would have a like effect. The dragging of the outer layer of gutta percha across the powder-core is a fertile cause of failure to explode the cap. In general we advise the square cut.—EDITOR.]

BOGOMOLOVSKY MINES: GENERAL VIEW AND WORKMEN'S HOUSES

The Bogomolovsky Copper Mines, Russia

By N. T. TRUSCHKOFF

These mines are in a pyrite belt on the eastern slope of the Ural mountains, formerly worked for gold until copper pyrite was found below the gossan.

The Bogomolovsky mines belong to the Bogoslovsk Mining Co.; they are situated 10 miles north-east of the station Goroblagodatskaya on the Perm & Gornozavodsk railroad in the Verhotursk district, department of Perm; they also lie six and one-half miles south-east of the station Verknaya on the Bogoslovsk railroad, which runs to the Bogoslovsk company's Nadejdensky iron works and connects the Perm with Bogoslovsk railroads, the Nadejdensky works being the terminal of the Bogoslovsk narrow-gauge line. A standard-gauge line is under construction now to connect the Bogomolovsky mines with Verknaya; this branch railroad was expected to be ready by the end of the current year. Eight and one-half miles south-west of the mines is the Government's Kushva iron works with its famous Mount Blagodat iron ore deposit; 10 miles south of the Kushva begins the Nijny Tagil—one of the largest and oldest mining districts in the Ural region, producing iron, copper, platinum, and gold. The accompanying map shows the relative position of the mines to the neighboring country. All the surface near the Bogomolovsky mines is covered by forest; the district is intersected by many small rivers, whose gravels have been worked by local diggers ('starateli') for gold and platinum. Bogomolovsky, however, promises to become far more important for its copper. Four small rivers are on the strike of the ore-bearing zone; going north they are Salda, its tributary Kushika, and Tva, with its tributary Kljuchovka, the Salda having enough water for a metallurgical plant. Two groups of mines were bought by the Bogoslovsk Mining Co. from Mr. Bogomoloff's successors: a western

group, consisting of two claims, Plastorazdelny and Verinsky, marked on the map, and an eastern group, adjoining the first one and including 21 claims, which represented the main gold-bearing area at the time of Mr. Bogomoloff's operations. Only the western group is being developed now, the prospecting work on the eastern group being barely started.

The copper-bearing zone trends north-south and includes the western group of two claims, to which adjoin four new Bogoslovsky claims. South of the Plastorazdelny claim are the Ponizovkin gold mines with a pyrite deposit, and two similar deposits belonging to Ushkoff & Co., producing pyrite for large sulphuric-acid plants and dye works on the Kama and Volga rivers, of eastern and middle Russia. North of the Verinsky claim are the so-called old and new Levinsky mines near the Kljuchovka river, on the Verkne Turinsk peasant lands, 3000 dessjatins (each 117,600 sq. ft.) of which are leased by the company under a special agreement. Farther north on Government land, up to the Emech river, intensive prospecting is in progress on all the ground controlled by the company; altogether an area more than 15 miles long by 1 mile wide belongs to the Bogoslovsk Mining Co. along the general strike of the ore-bearing zone. A subsidiary company is to be formed to operate this property. The country-rock is granite and 'keratophyre'; the granite is not productive where massive; the keratophyre represents, according to the Bogoslovsk Geological Survey, an effusive soda-felsite porphyry, the main constituents of which are albite and oligoclase, seldom hornblende. The rocks forming the larger part of the mineralized area are altered keratophyre and its derivatives, metamorphic schists, more or less chloritic, which vary in color, being dark-gray, red, yellow, and white.

Owing to the present political conditions only prospecting work and small development work are possible now. Ingersoll-Rand hammer-drills are mostly used in driving and sinking. The driving is done by contract at a price of 130 rubles per cubic sagene (\$65 per 343 cu. ft., or about \$9.30 per linear foot of 7 by 7 ft. drift) timbering and explosives included; stoping costs R75 per cubic sagene (a sagene is 7 ft.). An Eclair (Belgian make) 40-hp. belt-driven compressor delivering 300 cu. ft. free air per minute is working now, and an Ingersoll-Rand Imperial type XB2 compressor, of 1051 cu. ft. per minute capacity, has been ordered.

A village for the employees and workmen was under construction during the summer. Three-shift work of eight hours is carried on underground. The average earnings for Russian miners in the month of May last were: Drillers R3.77 (\$1.89 at pre-war exchange) per 8-hour shift, timbermen R4.64, trammers 4.50, day-laborers underground 3.14, surface 2.35, smiths 5.43, helpers 4.50, fitters 3.50 to 5.85. Besides Russians, who number only 50, Chinese and war-prisoners, up to 150, are employed, mostly on surface. War-prisoners underground receive R2 to 2.50 per shift on contract and R2 on day's pay. The average Chinese wages are R2 daily.

A modern reduction-plant is to be erected near the mines, with a sulphuric-acid plant. The ore now produced is transported to the Bogoslovsk works, where it is smelted in two water-jacketed blast-furnaces, 228 by 42 in., and 84 by 36 in. at the tuyeres, together with local ore from the Toorinsky copper mines.

Ventilation pit No. 203 and shaft No. 7 are poor in sulphur (7 to 12% S). The Bogoslovsk smelter has extra capacity for treating 60,000 tons of pyritic ore per annum, besides local ore. The addition of Bogomolovsk pyrite to the charge, owing to its sulphur, reduces the percentage of coke required and results in a considerable decrease of cost.

Conditions in Russia at the present are unfavorable for starting any large mining enterprise; but after the end of the War there will be great possibilities for an extensive development of the mineral regions. The present tangled situation will not last long. The defeat of the Bolsheviks, who temporarily control Petrograd and a few other industrial centres where the workmen are swayed by radical socialistic sentiments, is certain. The Bolsheviks represent Russia no more than the I. W. W. represent the United States. The heart of Russia is sound, and the mass of the people is against Germany. The Germans may make peace with Lenin, Trotsky, and other traitors and German agents from the Smolny Institute, but they can never make peace with real Russia. The extreme socialistic parties have no following among the bulk of the population. The more moderate parties and all the reasonable soldiers not spoiled by German propaganda are consolidating with the middle classes. The election for a constitutional assembly will help in the establishment of order. The accompanying photographs show the No. 1 shaft as it appears at the present time.

An M. S. Contract

The following contract was offered to the inventor of an improvement in flotation. We comment upon it on the editorial page.

AGREEMENT made and entered into this — day of June, 1917, by and between John Doe, party of the first part, and Minerals Separation North American Corporation, a corporation organized under the laws of the State of Maryland (hereinafter referred to as 'Minerals Separation'), party of the second part. Witnesseth:

WHEREAS Minerals Separation is the owner of or is interested in or controls certain patents for processes and apparatus for the separation or concentration of ores; and

WHEREAS Minerals Separation is engaged in the business of granting and has granted licenses for the use of said processes and apparatus to the owners of mines, mills, or dumps in which license agreement it is provided, among other things, that the said owners to whom licenses to use the said processes and apparatus have been granted shall not use any apparatus in the operation of said process manufactured by any one other than Minerals Separation without the consent of Minerals Separation in writing; and

WHEREAS the said Doe has invented an apparatus which is capable of being used for carrying out one or more of the processes owned or controlled by Minerals Separation; and

WHEREAS Minerals Separation is willing to consent that the aforesaid mine, mill, or dump owners, who are licensed under its various patents, may use the apparatus invented by the said Doe; and

WHEREAS it will be impossible to estimate the damage and injury done to Minerals Separation if the said Doe furnishes to the owners of mines, mills, and dumps, who desire to infringe the patents owned and controlled by Minerals Separation, apparatus capable of carrying out the process or processes owned or controlled by Minerals Separation; and

WHEREAS in consideration of the aforesaid consent of Minerals Separation the said Doe is willing to undertake that none of the machines hereafter sold by him will be employed by purchasers or users in the infringement of patents owned or controlled by Minerals Separation:

NOW, THEREFORE, in consideration of the sum of One Dollar each to the other paid, the receipt whereof is hereby acknowledged and in consideration of the mutual covenants hereinafter contained, the said Doe and Minerals Separation hereby mutually agree as follows:

1. Minerals Separation hereby agrees that it will consent that the owners of mines, mills, and dumps, who have been licensed to use the patented processes or apparatus owned or controlled by Minerals Separation, may use apparatus invented by Doe in the carrying on of any of said processes for the concentration of ore.

2. The said Doe agrees to pay to Minerals Separation,

for such consent, ten (10%) per cent of the gross selling price of each and every machine sold to licensees of Minerals Separation, payment of said commission to be made to Minerals Separation free of exchange in New York within ten (10) days after the delivery of or payment for each machine. In the event that any machines are sold to the owners of mines, mills, and dumps who are not licensees of Minerals Separation but who subsequently become licensees, the said Doe agrees to pay to Minerals Separation ten (10%) per cent of the gross selling price of each and every machine so sold as soon as Minerals Separation gives its consent to the purchaser to use the same.

3. The said Doe agrees that he will not sell any apparatus capable of carrying on the processes owned or controlled by Minerals Separation to anyone for the purpose of infringing patents belonging to Minerals Separation, and the said Doe hereby guarantees that none of the machines hereafter sold by him will be used to infringe the patents belonging to Minerals Separation.

4. In the event that any of the machines hereafter sold by the said Doe shall be used by the purchasers or users thereof to infringe any of the patents owned or controlled by Minerals Separation, then in that event the said Doe agrees to pay to Minerals Separation ten thousand (\$10,000) dollars as liquidated damages for each machine employed in infringing the patents owned or controlled by Minerals Separation.

5. This agreement shall be binding and inure to the benefit of the successors in interest of the said Doe and of Minerals Separation.

IN WITNESS WHEREOF the parties have hereto set their hands and seals the day and year first above written.

Wolframite in South China

A recent discovery of wolframite in marketable quantities has been made in Kwangtung province. Following the discovery the natives, and even the official deputies, mistook it for manganese or iron ore, until the high prices offered raised a suspicion that it must contain something different from the common metals. The Japanese first learned of the value of the so-called 'iron ore' in Hunan province, and offered about 27c. Mexican, or 17c. gold, per pound for it. Other buyers learned of the bargain, and offered better prices. Now the average ore commands about \$32 gold per 100 lb. at Canton. Much of the ore comes from Chengchow, adjacent to the border of Kwangtung province. It is transported on men's backs to Ping Shek, a distance of 60 miles. From here it is carried in junks down the North river to Shuechow, 80 miles, whence it is brought to Canton over the Yueh-Han railway. Haifong district has been reported to produce wolfram ore, but no actual mining has begun. Kwangsi province also is said to produce it. A Chinese company, while prospecting for antimony some time ago in Kwangsi, found small seams of wolfram in the Hochi district, 120 miles north-west of Linchowfu. The ore occurs in hard quartz, and the cost of mining is excessive.

Buying Combinations in the Metal Market

BY THE FEDERAL TRADE COMMISSION

CLOSE INTER-RELATION OF PRODUCERS, TRADERS, AND
LARGER CONSUMERS

*Before the War the control of the world's metal market was in the hands of a group of German metal-traders, who are primarily engaged in buying metal, or in acting as selling agents for producers, and in selling it to European and Asiatic consumers. From the standpoint of the American metal-producers they are to be regarded primarily in the light of buyers, although in a broader sense they might well be defined as traders, since they both buy and sell. The description of their activities here given is from the American point of view. In a general way, it may be said that in Germany is centered the control over many of the largest producers of metals, while the London Metal Exchange and silver 'fixing board' exercise and control the price-fixing power to such a degree that London has become the international market for almost all metals, and that London metal quotations set the standard for the metal business the world over.

With regard to the fixing of prices in the metal market the national and international metal cartels and syndicates are of primary importance. The metal trade is notable for the extraordinary degree in which it has been concentrated in the leading metal-producing and metal-consuming countries of the world. A comparatively small number of firms control this trade the world over, and most of them are more or less closely inter-related. These combines fix the price and regulate the production of the metals and metal products controlled by them in their respective territories, and thus indirectly have an important bearing on the price question as it affects the metal market. The part played by the banks in the control of the metal business is largely responsible for the internationalization of the metal trade. Through syndicate agreements, price cartels, and interlocking directorates, certain banks of England, Germany, Holland, Switzerland, and Belgium have managed to secure control over the largest metal plants and metal-selling agencies of the world.

Another interesting feature of the metal combines consists in the fact that a number of large and important industries are dependent upon the metal trade for their supply of raw materials. Among these the electrical and the chemical industries rank foremost. Almost half of the total copper production is used for electrical purposes.

This close inter-dependence as well as manifold other common interests have been instrumental in bringing about a far-reaching system of co-operation among the leading metal firms and industrial cartels and syndicates. Thus the Metallgesellschaft of Frankfurt before the War was the common selling agency for the French Aluminum Syndicate, and it serves in a similar capacity, together with Beer, Sondheimer & Co. of Frankfurt, and Aron Hirsch und Sohn, of Halberstadt, for the German Zinc Syndicate. Aron Hirsch und Sohn are members of the German Copper Sheet Syndicate and of the Combine of German Copper Wire Works. The Deutsche Gold- und Silberscheideanstalt is closely allied with the chemical industry and is a member of several chemical cartels. In 1900 it organized and managed a syndicate of calcium-carbide manufacturers. In the latter industry the Siemens-Schuckert concern, one of the groups that control the German electrical business, is heavily interested. By means of the Metallurgische Gesellschaft the Merton interests, which are the chief factor in the metal-buying combination, acquired large holdings in the German potash industry through the Gewerkschaft Rastenberg. On the chart opposite page 366 [on page 87 of this issue] the number and extent of these inter-relations is presented.

Through banks, holding companies, affiliations with syndicates and cartels, interlocking directorates, joint-share holdings, and other means of inter-relation, a world-wide ramification has taken place in the metal trade.

The following examples will illustrate how some of the more important metal concerns are allied through interlocking directorates. Of the Merton family, of Frankfurt and London, five members are directors in most of the companies controlled by or affiliated with the Metallbank of Frankfurt; R. Merton is connected with the Merton Metallurgical Co., London, the American Metal Co., Ltd., the Australian Metal Co., Ltd., and the Compagnie des Minerais de Liège. Walter Merton is a director of the Metallbank & Metallurgische Gesellschaft, Frankfurt a. M.; the Metallgesellschaft, Frankfurt a. M., and of the Merton Metallurgical Co., London. H. Gardner is on the board of directors of Henry R. Merton & Co., the Australian Metal Co., the Merton Metallurgical Co., the Mines de Pierrefitte, and Williams, Foster & Co. A. Ladenburg is a director of the Metallbank and of the Schweizerische Gesellschaft für Metallwerke. Walter vom Rath is a director of the Metallbank, the Metallgesellschaft, the Lahmeyer electrical concern, the Höchster Dye Works, and the Allgemeine Elektrizitäts Gesellschaft.

*Taken verbatim from 'Report on Co-operation in American Export Trade'; Federal Trade Commission; June 30, 1916.

The Frankfurt metal firms are also connected with some of the leading German banks through interlocking directorates, viz., the Hirsch concern with the Deutsche bank; the Deutsche Gold- und Silberscheideanstalt with the Metallbank, Frankfurt a. M., and the Oberschleisische Zinkhütten A. G., Kattowitz, with the Nationalbank für Deutschland.

SILVER. According to the statement of a large American concern, which exports about seven-tenths of its silver output to London, the silver trade of the world is dominated by the London Metal Exchange:

The price of silver is fixed in London by what is termed publicly the 'fixing board,' which consists of four banking or brokerage houses dealing in silver and Eastern exchange. This board of four representatives meets at a quarter past two every afternoon. This permits prices to be made in New York at the opening of business here, on account of the difference in time. Since virtually the entire silver business of London is in connection with exportations from the United States, it will be seen that the meeting-time in London is after the members of the fixing board know the full receipts and demands in London, but before business opens in New York. All silver in London is sold through these members of the fixing board. The distribution of silver in London, as stated above, is approximately 75% for shipment to the East, which is sold entirely to Eastern banking representatives, both English and continental, for coinage purposes, and, to a minor extent, to the manufacturers of silver. The Eastern banks and the Government representatives will not buy through anyone except members of the fixing board, and at the fixed prices, because if they do otherwise they take a responsibility which they do not seem to be willing to take. In fact, if they should buy in any quantity from other parties, the fixing board would probably fix a price that would make their purchase open to criticism. These four brokers, therefore, have the ability, and exercise it, to absolutely fix every day the price at which the entire product of the mines of the United States in silver has to be sold.

This fixing board has, however, a much greater power than that covered by the actual transactions in fine silver, for the reason that the commerce of the East, India, and the Straits Settlements and China is expressed in silver; in other words, the entire exchange transactions of London, covering the entire commerce between the continent of Europe and India, is expressed in silver values, and the price of silver is the price of exchange. These exchange transactions are at least ten times as great as the total value of silver purchased and sold in London. The great Eastern banks are the great buyers not only of silver for export to the East, but also of the exchange covering the commerce with the East. The silver value of the American mines is dominated by four brokers, designated as a fixing board.

COPPER. According to the statement of a large American concern, which exports about six-tenths of its copper output to Europe, prices established by the London Metal Exchange determined to a large extent prices of copper

at any port in Europe. Since the present War the British director of materials promulgated the following regulations in relation to sales of copper:

1. Orders up to and not exceeding 50 tons may be placed in the usual way, without reference to the Minister of Munitions.

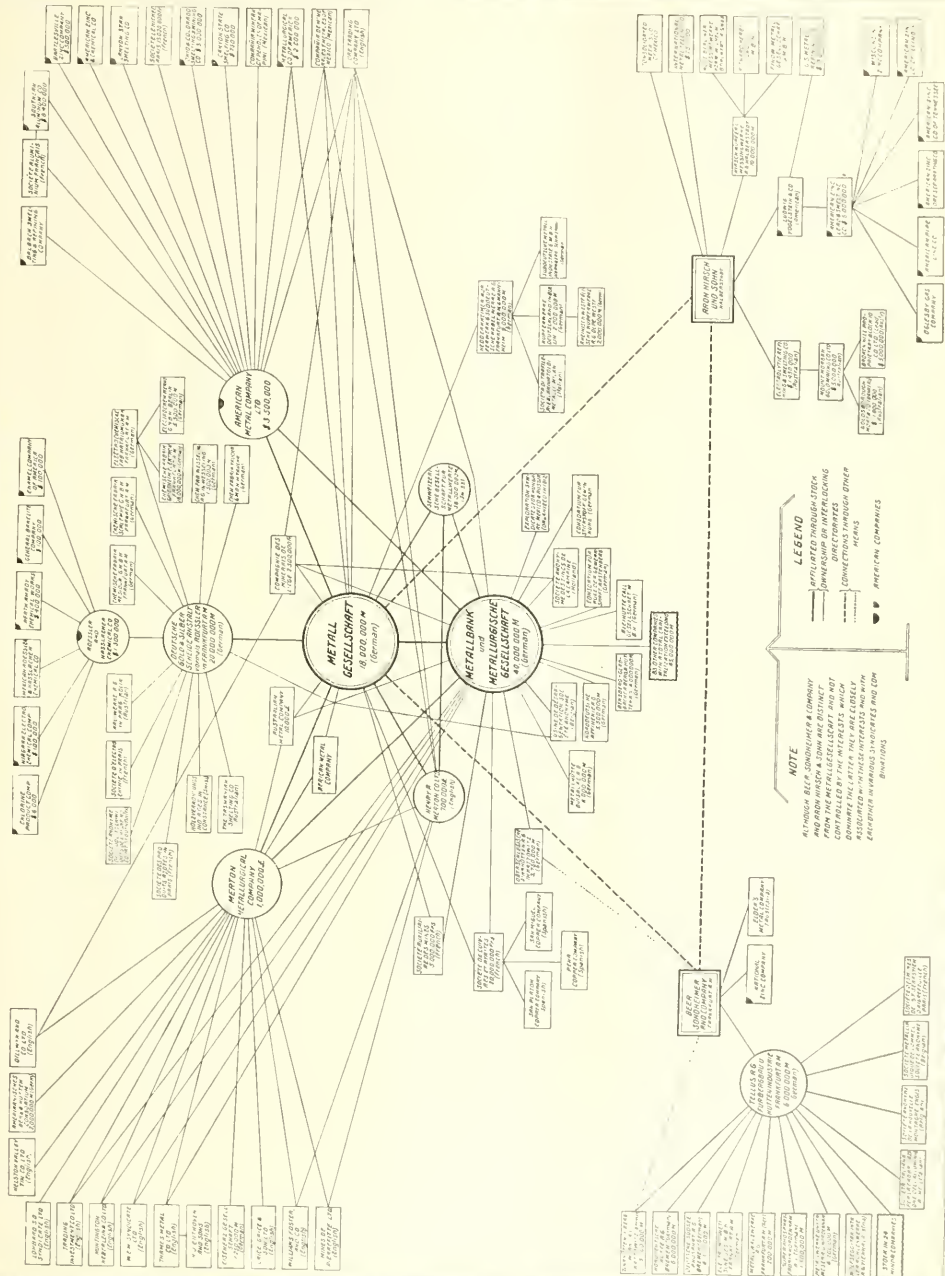

2. No orders for best selected or electrolytic brands of copper shall be placed at prices exceeding £100 per ton, without first consulting the director of materials.

Commenting on the effects of this order, the American concern said:

This action was taken on January 5 last. The immediate effect of this action with reference to copper was to stop the buying. The British Government, stating that they were acting also for their allies, Russia, France, and Italy, had previously negotiated large purchases of copper in this country for delivery spread out over a year. A very large proportion of the amount of copper exported is now being purchased by Governments, all acting in conjunction with one another, and is being distributed by these Governments to their manufacturers. Furthermore, we know that our sales of copper, made to the largest consumer of copper in France, are being distributed by them to their normal competitors at the present time.

On the subject of the purchase of copper by German buyers before the War, the American concern stated: The German consumption was such a large proportion of the total amount of copper exported that German buyers had more influence in fixing the value of copper than the English buyers. It was very evident to this company that the buyers of Germany at least worked as a unit. They would repeatedly remain out of the market for weeks at a time and would not accept any offer made, during which time the American sellers would accumulate such amounts of copper that they would be obliged to reduce their offers. The German buyer would wait until the offers were reduced sufficiently and then would come in again as the unit and buy in very large quantities. This process of buying at the lower and refusing to buy at the higher price, which was naturally stimulated by their very heavy buying at the low price, resulted in the average price at which the American buyer, who bought more regularly and was more inclined to buy at the panic high prices, could buy. The result is, so far as the sales of this company are concerned, and we believe that there is a similar condition on the part of other sellers of copper for exportation, the average export price is considerably lower than the average price obtained from the American consumers. The difference arises entirely from the selection as to the time of buying and not from the holding of a price at any one time by this company to American consumers above that offered to consumers abroad.

On conditions in the German market since the War began, the American concern said: In Germany at the beginning of the War a combination of all the large German consumers and metal merchants was made, known as the Kriegsmetall Gesellschaft. This combina-

tion has assembled and distributed the copper supply of the country. This is recognized as an incident of the War, but we are now informed it is proposed to continue this combination after the War is over. It would thoroughly and effectively combine all of the large tonnage of copper which has heretofore been purchased in this country, and place the American producers at a tremendous disadvantage. In Germany there are interlocking directorates, with large financial interests holding shares in the companies that are largest consumers of copper, which enables the management of the respective companies to act jointly in purchasing their requirements of copper in this country. The United States has heretofore supplied most of the copper used in Germany, and Germany has been the largest consumer in Europe.

The bearing of the conditions existing in the European markets on the copper industry in the United States may be understood when it is realized that the United States produces about 56% of the world's supply of copper, and exports about three-quarters of its annual production. In the year ending June 30, 1914, it exported 975,000,000 lb., valued at \$145,000,000, seven-eighths of the exports being in the form of pigs, ingots, and bars. Of the total quantity of exports, 96% went to Europe. Germany took one-third of the exports to Europe. In addition to the quantity purchased by the great German metal-buying combinations, headed by the Metallgesellschaft, many of the large consumers of copper acted in concert in their purchases, through their cartel arrangements. According to one large American copper-producing company, they had reports from their Berlin agent of the existence of more than 50 combinations of copper-consuming companies for the regulation of prices, distribution of territory, and for concerted action in buying. According to John D. Ryan, of the Amalgamated Copper Co., European buyers, from 1903 to 1913, because of a buying combination, paid 83/100 of a cent per pound less for copper delivered abroad than domestic buyers for copper delivered at New York.

ZINC. The German zinc syndicate (Zinkhüttenverband) was organized in February 1909 with a capitalization of 2,000,000 marks for the apportionment of the output and for the fixing of the sales prices of zinc. The active organizers of the syndicate were the Metallbank of Frankfurt, controlled by the Merton interests; the Frankfurt metal-selling and holding company, Beer, Sondheimer & Co., which, through the Tellus joint-stock company, controls over a dozen metal and chemical concerns; and the firm of Aron Hirsch und Sohn, at Halberstadt. Both the latter metal-dealers established their own new zinc works at the moment of the organization of the German zinc syndicate.

Seven zinc works of Silesia and six zinc concerns of the Rhenish-Westphalian region at once joined the syndicate. The Metallbank, Beer, Sondheimer & Co., and Aron Hirsch und Sohn were made the exclusive selling agencies of the syndicate and the agreement was to continue for three years. Only one important concern, the Georg von Giesches Erben, retained its right to deal

directly with the consumers, under the condition, however, that it should comply with the price-lists of the syndicate.

Immediately upon the organization of the German zinc syndicate (Zinkhüttenverband) an agreement was made with the Austrian and Belgian producers, of which the Vieille Montagne had works in Belgium, France, Algeria, Germany, Italy, England, Sweden, and Spain, and agencies in Tunis, America (United States), Japan, and Turkey. A Dutch concern (Zincs de la Campine) also joined the syndicate. The syndicate embraced altogether 18 firms. Ten Belgian and some French works formed another syndicate; so did six English works. During the same year, 1909, the competition of the United States concerns drove all these three groups together into the International Zinc Syndicate (Internationaler Zinkhüttenverband).

The International Zinc Syndicate was continued on November 10, 1910, up to April 1914. The syndicate agreement left the English and the French works free to fix their prices, and it is said that in some cases they underbid the German works. The agreement also provided that in case the reserve had reached 50,000 tons and the zinc prices in London had gone below £23 per ton the output should be reduced. Before the outbreak of the present War a 20% reduction of output was ordered.

The price changes made by the German Zinkhüttenverband always correspond to those made by the International Zinc Syndicate for the London Metal Exchange, which, it is said, gets its instructions from the Metallbank of Frankfurt, that is, from the combined Merton, Beer, Sondheimer & Co., and Aron Hirsch und Sohn interests. The zinc and other metal dealers of Germany act in unison as purchasers from any foreign concern.

By the end of 1912 the German Zinkhüttenverband controlled one-half of the world's output of zinc, and three-fourths of the European output. The International Zinc Syndicate regulates output only, while the German syndicate (Zinkhüttenverband) regulates both output and prices within its sphere. The actual price regulation is carried out by the Kölner Zinkhüttenverband, which appears to be but a subdivision of the German syndicate (Zinkhüttenverband). It must be remembered that the German syndicate has two distributing agencies—one in Cologne and the other in Kattowitz (Silesia). The published price quotations, however, do not represent strict sales prices, but form only the basic price on which the actual sales prices are computed.

LEAD. In 1908 an agreement was reached between German lead works and Australian lead-mine owners as regards prices and apportionment of markets. The competition of Spain and of the United States compelled the lead interests to organize in the spring of 1909 the International Lead Convention. The Australian Broken Hill mines, the American Smelting & Refining Co., some Spanish and some Mexican mines, the Usines des Désargatation of Antwerp, and the German Bleihütte 'Call' formed a common sales agency under the leadership of

the Metallgesellschaft in Frankfurt, in Germany, and of the Henry R. Merton & Co., in London. This convention was continued in June 1910 for several years.

ALUMINUM. Close relations exist between the Merton concern and the aluminum industry, especially the French Aluminum Syndicate, and through the latter with the International Aluminum Cartel formed in 1912. The Metallgesellschaft of Frankfurt was instrumental in organizing the French Aluminum Syndicate in November 1910, and since then it has served in the capacity of its common selling agency, which handles the entire export of the French Aluminum Syndicate. The following companies are members of the French syndicate: Société Electro-Métallurgique Française ('Froges'), Compagnie des Produits Chimiques d'Alais et de la Camargne ('Salindres'), Société des Forces Motrices et Usines de l'Arve, Société des Produits Electro-Chimiques et Métallurgiques des Pyrénées, Société Electro-Métallurgique du Sud-Est, and the Société d'Electrochimie.

Several aluminum factories also manufacture calcium carbide, and in 1900 the Deutsche Gold- und Silberscheideanstalt organized and managed a syndicate of calcium-carbide producers, which was dissolved in the following year. An international carbide syndicate was formed in 1910 for a period of 10 years, of which all of the 58 carbide factories of Europe (in France, Switzerland, Germany, England, Austria, Norway, and Sweden) became members.

The electrical industry has for many years been closely connected with the manufacture of calcium carbide, especially the Schuckert interests.

In October 1910 the following German producers organized the German Aluminum Purchasing Association (Deutsche Aluminum Einkaufsvereinigung):

Fried. Krupp-Grusonwerk, A. G.

Julius & August Erbslöh.

Karl Berg in Eveking.

Vereinigte Deutsche Nickelwerke in Schwerte.

Th. Goldschmidt in Essen.

Basse & Selve, Lüdenscheid.

Through this purchasing combine the metal industry was connected with the Krupp concern, the great steel, ship-building, ordnance, and munition manufacturers, on the one hand, and with the copper and brass industry on the other. Basse is one of the directors of the Lüdenscheider Metallwerke, A. G., formerly Jul. Fischer und Basse, a large consumer of metals, and a producer of fine machinery and various articles from copper, brass, and new silver. American metal exporters state that the Lüdenscheider Metallwerke, A. G., are also closely connected with the Metallbank of Frankfurt.

THE GERMAN METAL-BUYING COMBINATION

There are three main groups of interests which together dominate the German metal market. They are the group identified with the Merton family, including the Metallgesellschaft, the Metallbank und Metallurgische Gesellschaft, and the Deutsche Gold- und Silberscheideanstalt, the group identified with Beer, Sondheimer & Co., and the group identified with Aron Hirsch

und Sohn. The principal relationships of these three groups are shown on the chart.

THE METALLGESELLSCHAFT, METALLBANK UND METALLURGISCHE GESELLSCHAFT, AND H. R. MERTON & CO., LTD. The Metallgesellschaft, A. G., Frankfurt a. M., was founded in 1881 by Wilhelm Merton. It took over the metal business of his grandfather Philipp Abraham Cohen. Wilhelm Merton was the son of the senior member of the firm of Henry R. Merton & Co. of London. When H. R. Merton started in business, P. A. Cohen supplied part of the capital, conversely, later on, H. R. Merton and his brothers Zachary and Emile, who had later become associated with him, also had a proprietary interest in the Cohen concern. When the two concerns were formed into limited companies these interests were capitalized in the form of shares in H. R. Merton & Co., Ltd., and in the Metallgesellschaft, A. G., Frankfurt a. M. In 1878 the London and the Frankfurt interests had already joined in the foundation of the American Metal Co. As a result of the predominance of the influence of the Merton family in these three companies, they have been generally known as the 'Merton concern.'

For the purpose of attracting outside capital, and in order to distribute the risk entailed by large investments, participating and financing companies were formed. The first step in this direction was that the Frankfurt, London, and New York firms turned over to separate holding companies their interests in mines and smelting plants which they had acquired in the course of time. In this way, in 1897, there was formed, as a subsidiary company associated with the Metallgesellschaft, the Metallurgische Gesellschaft, Frankfurt a. M. (capital 6,000,000 marks); in 1907, as a subsidiary company associated with the American Metal Co., the Metallurgical Co. of America (capital \$2,000,000).

As the sphere of business interests of the Merton concern expanded into other countries outside of Germany, England, and the United States, the following additional holding companies were organized: The Compagnie des Minerais, Liège (capital 2,500,000 francs); the Société auxiliaire des Mines, Paris (capital 5,000,000 francs); and the Compañia de Minerales y Metales, Mexico. Together with the French banks, C'ahen d'Anvers, the Société générale pour favoriser le développement du Commerce et de l'industrie en France, and other capitalistic groups, the Société des Cuivres et Pyrites, Paris (capital 30,000,000 francs), was organized in 1907 for promoting the development of three Spanish copper companies, the San Platon, the San Miguel, and the Pena Copper Company.

Two subsidiary companies of the Metallgesellschaft and of Henry R. Merton & Co. are the African Metal Co. and the Australian Metal Co. of London and Melbourne, respectively. They attend to the purchase and sale of metals in their respective parts of the world in behalf of the two parent concerns.

In 1906 the Berg- und Metallbank A. G., located at Frankfurt, was organized with a capital of 40,000,000 marks. This holding company was founded by the

Metallgesellschaft, together with the Metallurgische Gesellschaft, the Deutsche Gold- und Silberscheideanstalt, the Darmstadter Bank, the Berliner Handelsgesellschaft, the Diskontogesellschaft, and several private bankers of Frankfurt. From one-quarter to one-third of the capital in the principal undertaking of the Merton concern was turned over to the Berg- und Metallbank. In 1910 the Berg- und Metallbank A. G. was consolidated with the Metallurgische Gesellschaft into the Metallbank und Metallurgische Gesellschaft A. G., Frankfurt a. M., with a capital of 40,000,000 marks.

A chart showing the principal inter-relationships of the various companies in the group which centre in the Metallgesellschaft and the Metallbank und Metallurgische Gesellschaft has been prepared by the Commission, and is inserted in this volume. A preliminary chart was first prepared from information derived from a large number of published sources, chief among which were the article by Prof. Robert Liefmann in the 'Weltwirtschaftliches Archiv' for January 1913, various articles in the 'National Review' (London), the Mining and Engineering Review' (Melbourne), and other periodicals. The preliminary chart was then submitted for criticism to a number of Americans who are well informed in regard to the international metal situation and are acquainted with the organization, operation, and control of the companies shown on the chart. A final chart was then prepared, embodying the changes that were found to be desirable, in the light of the information gathered through such co-operation. The Commission believes that the chart herewith presented shows the principal companies and their inter-relationships, as they existed at the time of the outbreak of the present War. It is generally understood that as a result of the War there have already been a number of changes in such relationships, and that more are likely to take place.

It should be noted that the relationships shown on the chart indicate either stock control, stock inter-ownership, interlocking directorates, or syndicate connections. These relationships, the Commission is informed, are of such a nature that they lead to a centralized price control and to a harmony between the policies followed by the different companies in their purchases of metals. Connections also exist with other companies, but these have not been put on the chart because the Commission does not understand that they are effective in price control.

In the group of companies which are largely the outgrowth of the Merton concern, the dominating place has been held by the Metallgesellschaft, the Metallbank und Metallurgische Gesellschaft, and the H. R. Merton & Co., Ltd. The affiliations of these companies through stock ownership and interlocking directorates is so close that it is difficult to determine which company is the dominating concern. The two largest subsidiary companies are the Merton Metallurgical Co. and the American Metal Co., Ltd. Apart from these two companies and their subsidiaries, the chart shows connections between the three controlling companies and 24 companies (excluding the Deutsche Gold- und Silberscheide group).

Most of the connections were through stock ownership, either alone or in connection with interlocking directorates. In addition, mention is made of the fact that similar relations exist with 83 companies whose names are not separately shown.

While the chart shows 13 companies related to the central group through the American Metal Co., and a like number related through the Merton Metallurgical Co., attention should be called to the fact that many of these 28 companies are, at the same time, connected with one or more of the central group and with other companies directly connected with it. In all, the chart shows the names of 54 companies of the 137 companies (excluding the Deutsche Gold- und Silberscheide group), of whose inter-relation to the Metallgesellschaft the Commission has information. Among the important companies not mentioned on the chart in which the Metallbank und Metallurgische Gesellschaft holds shares are the Société des Anciens Etablissements 'Sopwith' of Paris and Linares, the bank of Delbrück Schieckler & Co. of Berlin; the Mitteldeutsche Versicherungs, A. G., Düsseldorf; the Allgemeine Revisions und Verwaltungen, A. G., Berlin; the Solotwina Naphta, G. m. b. H., Lemberg; the Oesterr. Petroleum-Industrie, A. G., Vienna.

THE DEUTSCHE GOLD- UND SILBERSCHIEDANSTALT. In 1872 the Deutsche Gold- und Silberscheideanstalt was established by the firms of Fr. Roessler Söhne and Hector Roessler, and in 1873 took over the precious metal business of Philipp Abraham Cohen. Close relations exist between the Merton interests and the Deutsche Gold- und Silberscheideanstalt, which is itself a widely ramified concern, is interested mainly in the chemical industry, and serves as the central agency for several cartels, among them the Convention of Manufacturers of Potassium Ferrocyanide, the Convention of Manufacturers of Potassium Cyanide, and the Convention for Quinine and Quinine Salts.

On the chart the connections in the nature of either stock-ownership, interlocking directorates, or both are shown between the Deutsche Gold- und Silberscheideanstalt and 20 minor companies. The direct connections shown are principally through stock-ownership. In addition to the connection shown on the chart with the Metallgesellschaft, the Commission has information concerning a number of inter-relations between companies of the Deutsche Gold- und Silberscheideanstalt group and those of the Metallgesellschaft, Metallbank und Metallurgische Gesellschaft, and H. R. Merton Co., Ltd., group, which it is not practicable to present diagrammatically.

ARON HIRSCH UND SOHN. The firm of Aron Hirsch und Sohn, of Halberstadt, is an important unit in the international metal trade around which numerous subsidiary and otherwise related companies are grouped. It is also closely associated with a number of German and international cartels. It is one of the three selling agencies of the international zinc syndicate of Germany. It is a member of the German Copper Sheet Syndicate, Cassel, and of the Combine of German Copper Wire

Works, Cologne. It holds an interest in the firm of Paul u. Siegbert Lachmann, the copper mine Isenberg am Harz, and the brass works Eherswalde on the Finow Canal. It controls the Hirsch, Kupfer- und Messingwerke, A. G., in Halberstadt (capital 10,000,000 marks), which manufactures chiefly copper and zinc products for railways, shipbuilding, and military purposes. The firm of Hirsch, Kupfer- und Messingwerke holds an interest in the Berlin Brass Works, Wilhelm Borchert, Jr., G. m. b. H. (capital 1,000,000 marks), and in the Rich. Herbig & Co., G. m. b. H., Berlin, and controls the Finow Metal Co., Ltd.

In Australia Aron Hirsch und Sohn are interested in such important metal enterprises as the Electrolytic Smelting & Refining Co. and the Mount Morgan Gold Mining Co., Ltd., one of the largest Australian copper-producing companies. Through the latter company Aron Hirsch und Sohn are connected by common directors with Goldsbrough Mort & Co., bankers and brokers and with the Broken Hill Proprietary Block 10 Co., Ltd. The international ramifications of the Hirsch interests also extend to numerous companies in the United States and Mexico. The firm of Ludwig Vogelstein & Co., New York, of which the firm of Aron Hirsch und Sohn is a special partner, serves as intermediary between the Hirsch interests and several of the American companies. The chart shows the names of 19 companies which are connected directly or indirectly with the firm of Aron Hirsch through interlocking directorates or stock-holdings.

BEER, SONDHEIMER & CO. The firm of Beer, Sondheimer & Co., Frankfurt a. M., is the centre of another large group of enterprises in the international metal trade, and ranks next in importance to the Merton concern, with which it has certain interests in common. In 1906 Beer, Sondheimer & Co. founded the Tellus A. G. für Berghau und Hüttenindustrie. This company in turn controls, through stock-ownership, or interlocking directorates, 36 other companies, the names of 12 of these concerns being shown on the chart. Beer, Sondheimer & Co. also are connected with the National Zinc Co. (New York), and the Elder's Metal Co., of Australia. The international character of its business is seen from the fact that in the group are German, Austrian, Italian, Belgian, French, American, and Australian companies.

THE RANGE of activities of the U. S. Bureau of Standards is shown by the recent annual report of the director, which states that 155,000 tests of weights, measures, and instruments were made during this year, a new standard screen-scale and new gauge-standards for testing munitions gauges was prepared, together with investigations covering the accuracy of leather-measuring apparatus, standardization of blood-counting apparatus, standardization of master scales in 21 States and of those used by the American Railway Association, extension of the work on altitude-measuring instruments including those used in aviation, and also special researches in the physics of materials.

Electrolytic Zinc

In making electrolytic zinc, according to Joseph W. Richards, the presence of manganese in the solution is of advantage during electrolysis; in fact, at the electrolytic plant at Nelson, B. C., a manganese salt is said to be added to the solution because of its beneficial action during the electrolysis. The manganese separates out on the anodes as manganese di-oxide, helping to prolong their life and also furnishing indirectly a method of extracting the manganese from the raw materials used in the manufacture of the soluble manganese salt. It is quite true, however, that small amounts of certain impurities render difficult the deposition of the zinc in coherent form, and great care must be taken to maintain the purity of the electrolyte. He takes exception to the statement that all the factors necessary to the production of electrolytic zinc were known long ago. One of the most important factors recently determined is the extent to which the zinc can be extracted from the solution, leaving the solution acid. Many thousands of dollars have been spent in experiments during the last few years to determine just how far the electrolysis can proceed and the acidity of the solution be increased without decreasing too much the deposition of the zinc. He thinks that not enough emphasis has been placed on the possibility of the electrolytic methods replacing the retort methods for zinc. He bases his prediction on the fact that the retort methods have been used for over a hundred years and at the present time are being only very slowly improved, whereas the electrolytic methods have been in use not more than five years and are susceptible of very much greater improvement. He thinks that where one may expect a possible improvement of 10% in the retort processes in, let us say, the next five years, there is a possibility of an improvement of perhaps 50% in the electrolytic processes. One must not overlook the possibility of a relatively much greater improvement in the new electrolytic methods, and he affirms that the Joplin territory will very soon see an invasion of electrolytic zinc, as has been pointed out, for their special concentrates or special kinds of ore.—Amer. Inst. Min. Eng.

ALASKAN mines are believed to have produced gold to the value of about \$15,450,000 in 1917, compared with \$17,240,000 in 1916. The total value of the gold mined in the Territory is now about \$293,500,000, of which \$207,000,000 has been won from placers. In 1917 about 88,200,000 lb. of copper was produced in Alaska, valued at about \$24,000,000. The production in 1916 was 119,600,000 lb., valued at \$29,480,000. The total copper produced to date is 427,700,000 lb., valued at \$88,400,000.

PYRITES from domestic sources is now quoted at 25 to 30c. per unit of contained sulphur. Spanish pyrites is still quoted at 16c. per unit, but foreign prices are based on the freight rates. The seller pays up to 13 shillings and the buyer the difference. Freight today are from 30 to 35 shillings per ton.

California Metal Production in 1917

The mines of California made an output in gold, silver, copper, lead, and zinc, valued in all at \$41,457,692 in 1917, compared with \$39,749,263 in 1916, according to preliminary figures compiled by Charles G. Yale of the San Francisco office of the U. S. Geological Survey. This is an increase of \$1,708,429.

The mine output of gold in 1916 was \$21,410,741. The estimated output of gold in 1917 is \$21,098,915, a decrease of \$311,826. If this estimate is correct, the slight decline in the gold output of the State in 1917 as compared with 1916 is much less than has been expected in view of conditions that have existed since the United States entered the War. These conditions have affected the deep mines more unfavorably than the placer mines. There has been, and still is, a scarcity of skilled labor, as machine-men, timber-men, and skilled miners have been attracted elsewhere by the higher wages paid in munition factories, copper and coal mines, and other industries that supply demands made urgent by the War.

The higher cost of nearly all mining supplies, and the increased taxation have made it impossible to operate at a profit some of the large mines that have been working low-grade ore. A number of the smaller mines have therefore already been closed, and some of the larger ones will stop ore-producing and milling ore this winter, and will do development work only and keep down the water. Some operators say that the purchasing power of gold has so greatly declined that they are virtually getting only about \$10 an ounce for their gold. Meetings were held in San Francisco in December by the prominent gold operators to protest against any discrimination through freight priorities aimed at the mining of gold as non-essential to the conduct of the War. It was feared also that the supply of explosives for use in mining might be cut off on the same ground. These apprehensions and the existing conditions have caused great unrest among gold miners, and as a result prospecting and development have almost stopped.

The deep mines of California are now producing about 60% of the gold output of the State, the other 40% coming from the various placer mines, principally through dredging. The proportion of the gold output of the State derived from placers is thus increasing. The gold-dredging industry continues prosperous, and few changes have occurred in the general conditions. In all the larger enterprises a greater effort is being made to save more gold. A few dredges are re-working old tailings with profit. Some of the largest and most expensive dredges ever built have been put to work in 1917. A number of old dredges have been dismantled and their machinery has been put into boats for use at new places. A few have gone out of commission altogether, their available ground having been worked out. Some new machines have been installed on new ground in the 'outside' districts of the State. Neither hydraulic nor drift mining shows any marked revival, though several old

hydraulic mines that have been idle for more than a quarter of a century have been re-opened, and search is being made for available ground where conditions are favorable for constructing the dams and basins required for impounding the débris.

The output of silver is estimated at 2,144,196 oz., valued at \$1,745,375, as compared with 2,564,354 oz., valued at \$1,687,345 in 1916. This silver was derived mainly from copper and lead ores, although some is mined with the gold. Owing to the rise in value of silver, a number of old mines in San Bernardino and Inyo counties that were once worked profitably, but that for years have been idle, are now being re-opened. Notable among these are the mines at Calico, which were at one time large producers. None of these properties, however, yielded much silver in 1917.

The estimated mine output of copper is 57,591,195 lb., valued at \$15,664,805, as compared with 55,897,118 lb., valued at \$13,750,691 in 1916. Labor troubles during the year restricted somewhat the output of the most productive copper mines in the State, and thus affected the total. Shasta county was by far the largest producer in 1917, but Calaveras, Placer, and Plumas counties now have very productive mines, with their own reduction plants, and there are many smaller productive copper mines in other counties.

The output of lead in 1916 was 12,407,493 lb., valued at \$856,117; the estimated output in 1917 is 23,189,974 lb., valued at \$2,133,460. Nearly all the lead comes from Inyo, San Bernardino, and other counties in the southern part of the State.

The estimated output of zinc in 1917 is 9,158,851 lb., valued at \$815,137, as compared with 15,256,485 lb., valued at \$2,044,369 in 1916. The zinc comes entirely from Shasta and Inyo counties. Every one of the larger companies made a reduced output in 1917.

Alaskan Mineral Output in 1917

In 1917 Alaska produced minerals valued at \$41,760,000, as determined by an advance estimate by G. C. Martin of the U. S. Geological Survey. This is about \$6,870,000 less than that in 1916. The leading product was copper, being 88,200,000 lb., valued at \$24,000,000. This is less than the output of 1916, which was 119,600,000 lb., valued at \$29,480,000, but is greater than that of any other year. The reduction is due largely to labor troubles, and is not necessarily permanent. The gold production was \$15,450,000, of which \$9,850,000 was derived from placer mines. The reduction from \$17,240,000 in 1916 was due chiefly to curtailment due to the scarcity of labor and the high cost of materials, but, in part, to the disaster at the Treadwell mine and the depletion of some of the richer placers. Alaska also produced silver, valued at \$1,050,000, coal worth \$300,000, lead \$160,000, tin \$160,000, antimony \$40,000, and tungsten, chromium, petroleum, marble, gypsum, graphite, and platinum, valued at \$600,000.

Mining in the North-West

By FRANCIS A. THOMSON

While there may have been slightly less activity during 1917 than in 1916, the year as a whole has been a prosperous one in the North-West. Changes in market conditions and in the labor situation brought about by our entry into the War have disturbed operations, but the situation as a whole, provided relief from the war-tax is secured, is fairly promising.

The supply of labor has been reasonably adequate. The lead-gold-silver mines are having to pay a price dictated largely by conditions in the copper districts, without the compensation of a fixed price at a fairly high level. The miners, however, have shown less disposition to listen to anarchism and the I. W. W. than the workmen in other industries.

The extension of smelting facilities at Northport and the entrance of the Bunker Hill & Sullivan company into the ore-market have been favorable features for the lead-gold-silver mines. The closing of the Trail smelter across the line and the reduced scale of operations at the B. C. smelter at Greenwood and at the Granby plant at Grand Forks due to coke shortage have hurt the small copper producers.

No material change in transportation facilities has taken place, if we except the Pine Creek branch of the O. W. R. & N., which will afford an outlet for the promising zinc-lead producers of this comparatively new district of the Coeur d'Alene region.

In the line of legislation the outstanding feature of the year is, of course, the War Tax law, which, because of its inequities and "inartificialities," as Judge Turner's pleasant euphemism has it, promises to bear with great harshness on those concerns which have been commendably conservative in the matter of capitalization. Doubtless relief will come in time, but meanwhile some of the mining companies are having to cancel dividends to stockholders in order to declare them in favor of the tax-gatherer. Against this the mine-owners would not protest if they felt that all other concerns were carrying an equal load. A second line of Federal legislation that directly affects the mining industry is the Explosives Act. This is designed to prevent explosives falling into the hands of alien enemies and is a highly commendable piece of legislation. The administration of the law is placed in the hands of the Director of the Bureau of Mines, who is given full authority for carrying out its provisions. The fear that the administration of the act might result in restriction of mining operations does not seem justified.

The year has been singularly devoid of new discoveries. Several of the larger properties in the Coeur d'Alene have responded favorably to new development, and the

Pine Creek district should soon begin to make a place for itself in the zinc and lead statistics.

An interesting innovation is the dredging operation that the Yukon Gold company is beginning near Murray on the north fork of the Coeur d'Alene river, one of the Yukon boats having been 'transplanted' for the purpose.

In Stevens county the continued development of the great magnesite deposits and the erection of kilns, with the steady shipment of both calcined and raw products, continues to be a gratifying feature of the contribution that our mineral deposits are making to the War. At Loon Lake, also in Stevens county, development of copper prospects long known but little valued is proceeding with encouraging results. In a small way the same thing is true of the copper prospects in the Hoodoo district of Latah county. Good reports continue to come in from the Marshall Lake district in central Idaho, and several other quartz properties in this once famous placer locality are giving evidence of new life.

The outstanding feature in metallurgical construction is the Bunker Hill & Sullivan smelter. Designed by the most experienced firm of smelter engineers in the West, and with the greatest silver-lead mine in the world to supply the wherewithal, it stands as the last word in this type of construction. Of steel and concrete throughout, it affords a startling contrast to the older plants, which, like Topsy, have "just grown" in response to an ever-varying ore-supply. From automatic charge-weighing hoppers to refinery, and from Dwight-Lloyd roasters to bag-house and Cottrell plant, everything is as complete as money and brains can make it.

Flotation continues to find wider application, the tendency being about equally divided between pneumatic and agitation machines of various types; and so far the Minerals Separation company seems disposed to content itself with an occasional circular letter to the operators.

To the student of mining litigation the year has been unusually interesting, there having been three major cases, each of a different character, involving in turn the three greatest properties of the Coeur d'Alene. First is the suit of the American Smelting & Refining Co. against the Bunker Hill & Sullivan company, by which the former claims breach of contract and seeks to prevent the latter from treating its own ore in its own smelter. From the appearance of things at the new smelter it is evident that the owners of the Kellogg plant have no expectation of being put out of business. The next suit in point of interest is the apex litigation of *Star v. Federal*, involving ownership of orebodies adjacent to the Morning mine at Mullan. As in most cases of the kind, the public has been highly edified by the startling differences of

opinion among eminent members of the mining profession upon matters where substantial unanimity would be expected. The man in the street begins to wonder whether economic determinism has not become a controlling factor among the adherents of a certain school of geological opinion. Like other defects in our system of litigation, the matter of ex parte expert testimony has waited long for remedy. Decision on this case has not yet been rendered; the orebodies in question are extensive and valuable and the future of each of the parties to the suit depends to a considerable extent on the outcome. Either a comparatively unknown prospect will at once become a big mine or the Star company will lapse back into obscurity and the great Morning mine will pursue the even tenor of its way. The last great suit of the year is that of Cardoner v. Day for annulment of sale on grounds of alleged fiduciary relationship between buyer and seller, and of inadequacy of consideration. Late in 1916 Mrs. Cardoner received \$375,000 for her one-sixteenth interest in the Hercules mine. Testimony concerning the value of the property involving principles of mine-valuation was offered by defendants themselves and by their engineer to the effect that the present value of the property was approximately \$5,000,000, on which basis Mrs. Cardoner received a fair consideration for her interest. Mrs. Cardoner's engineer places the value of the total ore in the mine at \$10,750,000 and assigned a life of 13½ years to this amount of ore at present production. The present value of this amount of ore distributed over 13½ years at any rate of interest between 7 and 10% is from \$4,500,000 to \$5,000,000. This corroborates the testimony of the defense. Decision is expected any day.

The effect of the War on mining is disquieting. The demand for lead is sluggish, due doubtless to a cessation of normal construction and painting demands, to the fact that ammunition is being made largely in England, and that lead supplies for this are presumably coming from Spain and Australia. In zinc the situation is disquieting, partly because England is becoming a large producer from Australian ores, and at the Government price for copper many of the smaller producers are not making much money. We are getting subnormal prices for the metal and paying abnormal prices for labor and supplies. Having been smitten on this cheek, Uncle Samuel asks us to turn the other one and let him swat us with an ill-considered war-tax. The possibility of dollar silver is the one ray of hope on the horizon of the coming year.

In conclusion, lest this be considered a tale of woe, let me say from an intimate contact with the mining industry of this part of the North-West, that those responsible for the productive operations are not only able and willing, but even anxious, to carry their share of the war load. They are giving their valued technical men to the Army, they are subscribing and over-subscribing to Liberty loans, and they are donating to 'drives' without stint. As one operator put it a few weeks ago, "Uncle Sam can have all we've got if it's necessary in order to

lick the Kaiser, he can take our mines and our mills if need be, and we'll live on turnips and carrots if Hoover says so, but at the same time we expect the other industries to tote their fair share of the load."

Mineral Production in South Africa

The value of all the minerals produced in the Union of South Africa for the month of August amounted to \$17,569,277. The gold production was 757,202 fine ounces, valued at \$15,652,557, of which the Transvaal alone yielded 757,146 fine ounces, worth \$15,651,404. The Union also produced 944,757 tons of coal, worth at the pit's mouth \$1,435,019, of which the Transvaal contributed 618,314 tons, worth \$717,342, and the Orange Free State 76,833 tons, valued at \$96,259. The copper production of the Union amounted to 593 tons, valued at \$142,720. Out of 225 tons of tin produced, the Transvaal supplied 223 tons, worth \$167,904. The profit earned by the Transvaal gold mines in August fell to \$4,287,387. With the exception of that for February, the return is the lowest for this year, and compared with August 1916 it is a reduction in profits amounting to \$574,247. However, the Rand companies show a profit of \$34,084,966 for the eight months of the present year. During the past year working-costs have advanced on the Transvaal gold mines from \$4.38 to \$4.66, of which 12c. per ton has been neutralized by higher recovery. It is noticeable, however, that the tonnage handled is 126,000 lower than a year ago. In August the Rand output amounted to \$15,111,930, equal to \$6.51 per ton; working-profits were \$4,182,839, representing \$1.82 per ton. The general aggregate was severely affected by the poor profits of certain mines in the Germiston district, but fortunately the splendid progress of the Far Eastern Rand was more than maintained. The 10 mines of that district show profits totaling \$2,034,197, or nearly half the profits of the whole Rand. Eight of these mines made a profit of over \$2.43 per ton, while four returned over \$486,500 worth of gold. The total mineral production of Southern Rhodesia for August amounted to \$1,789,076. Of this, the output of gold reached 70,259 fine ounces, worth \$1,432,499, and the yield of silver was 17,768 oz., worth \$10,886.

THE Federal Aid Road Act is benefiting all the States of the Union. The appropriation was 75 million dollars for the construction of post-roads and 10 million for forest-roads. In 1916 there were approximately 41 million dollars of State funds expended for all highway purposes, and it is estimated that in the calendar year 1917, the aggregate expenditures of State funds for this purpose will be at least 60 millions. A number of the States have made appropriations to meet the Federal aid dollar for dollar. Further information regarding this work may be obtained from the Director of the Office of Public Roads of the Department of Agriculture.

Nevada Mine Output in 1917

The value of the gold, silver, copper, lead, and zinc mined in Nevada in 1917 was over \$53,000,000, according to preliminary figures compiled by Victor C. Heikes of the U. S. Geological Survey. This total represents an increase of over \$3,000,000 in spite of the fact that there was a slight decrease in recoverable zinc and a marked decrease in both gold and silver. There was a fair increase in the output of both copper and lead. The average prices of silver, copper, and lead were unusually high in 1917, and this fact had much to do with making the total value greater than that of the previous year.

The gold output of Nevada was valued at about \$6,852,000, a decrease of about \$2,000,000. This decrease was due in great part to the reduced output of the Goldfield Consolidated Mining Co., which has for years been the main gold-producer of the State. The production of the Tonopah district, the ores of which contain considerable gold, was also less. The gold output was valued at about \$1,612,000, against \$1,941,441 in 1916. The main producers were the Tonopah Belmont, Tonopah Mining Co., Jim Butler, Tonopah Extension, and West End. Much gold came from the Elko Prince, the Aurora Consolidated at Aurora, the Round Mountain placer and quartz properties, the Rochester district, and the mines at Manhattan, where there was renewed activity. At the White Caps mine a large orebody is developed from five levels. The new mill, with roaster, was active during the last part of the year, making a considerable output. The War Eagle, Big Pine, and Union Amalgamated mills were also operated, and a large amount of placer gravel was treated by 12 operators. Bullion production from Seven Troughs district decreased, as did the placer output from the Battle Mountain district of Lander county, but the mills in Eldorado canyon, in Clark county, were unusually active. The National mine, a large producer in the past, was unproductive in 1917. About one-sixth of the gold came from copper ore and lead ore, mainly from copper ore.

The production of silver decreased from 13,837,525 oz. in 1916 to about 11,394,000 oz. in 1917. The price of silver, which averaged about 81 cents per ounce, gave this output a value of \$9,229,000, which is slightly more than in 1916. The principal silver-producers were the mines at Tonopah, the Nevada Wonder, the Rochester Mines Co., Nevada Packard, Elko Prince, Comstock properties, Yellow Pine, and Nevada Hills. With the improved price it was possible to treat low-grade ore, especially at Tonopah, where the silver output decreased to about 7,500,000 oz. from 8,734,726 oz. in 1916. The Tonopah Belmont, Tonopah Mining, and Tonopah Extension each produced more than 1,000,000 oz. of silver as well as considerable gold. The Mexican mill at Virginia City treated custom ore, largely from the Union Consolidated mine, but the bullion output of the district was much less.

The copper production of Nevada increased to nearly 110,000,000 lb., an increase of nearly 5,000,000 lb. over

that of the previous year. The value of the output increased from \$25,858,736 to about \$32,000,000. The main copper-producer, as formerly, was the Nevada Consolidated at McGill. This company was milling over 300,000 tons of ore per month and shipped a first-class product. The production from the smelter was somewhat less than in 1916, but the loss was more than compensated by the operation of the Mason Valley plant, in Lyon county. A large part of the ore treated came from the Bluestone mine, considerable quantities of copper ore were shipped to other copper plants, especially from the Yerington district in Lyon county, the Santa Fe and Silver Star districts of Mineral county, and from the Robinson district in the vicinity of Ely. The Copper Canyon Mining Co., in the Battle Mountain district, made a large output. The Consolidated Copper Mines Co., at Ely, contributed a noteworthy quantity of both crude ore and concentrates. The mill was remodeled and improved, and toward the close of the year treated more than 600 tons per day.

The production of lead increased from 25,637,278 lb. in 1916 to over 28,000,000 lb. in 1917. The value of the output increased from \$1,768,972 to about \$2,537,000. The principal lead-producing districts are the Pioche of Lincoln county, particularly the Prince Consolidated mine, and the Yellow Pine district of Clark county. The Bullion and Goodsprings Anchor properties, in the Yellow Pine district increased their output of lead. Considerable ore was mined at the Groom property, in southwestern Lincoln county, at the Hamburg property near Pioche, at the Union Mines Co., and at properties in the Eureka district of Eureka county.

There was a decrease in the production of recoverable zinc from 32,443,189 lb. in 1916 to about 28,500,000 lb. in 1917. The value of this output decreased considerably from over \$4,000,000 to about \$2,613,000. The Yellow Pine property, in Clark county, continued to supply the largest quantity of zinc produced by any mine in the State. The Potosi mine of the Empire Zinc Co. was also a large producer. Zinc was also produced by the Nevada Zinc Mining Co. in Elko county, the Lone Mountain district in Esmeralda county, and Ely in White Pine county.

The dividends declared by Nevada mining companies in 1917 amounted to over \$11,000,000. The largest was that of the Nevada Consolidated, which paid over \$8,000,000. Others were the Tonopah Belmont, Tonopah Mining Company, Jim Butler, Yellow Pine, Nevada Hills, Tonopah Extension, Boss, West End, Hamburg, Nevada Wonder, Uvada, Rescue Eula, and Prince Consolidated.

LITHOPHONE manufacturers are so far sold out that they are reported to be withdrawing from the market. The market is strong, with prices advanced as high as 7c. per pound, and predictions are for still higher figures. Prices of zinc oxide are also good, spot commanding 12½ to 14c. Producers are sold out three months ahead, with contract prices at 14c. for white seal, and 13c. for red seal.

Metal Mining in Montana in 1917

The value of the gold, silver, copper, lead, and zinc mined in Montana in 1917, according to the estimate of Victor C. Heikes of the U. S. Geological Survey, was nearly \$113,000,000, a decrease of more than \$20,000,000 from the value in 1916. There was an increase in the production of lead in the State, but a marked decrease in that of gold, silver, copper, and zinc. The mines at Butte and the smelters at Anaconda and Great Falls were idle two months on account of labor strikes. The prices of metals, except zinc, were unusually high. The cost of labor and material was also high.

The gold mined was valued at \$3,371,000, as compared with \$4,550,494 in 1916. The decrease in the output of copper ore reduced the output of both gold and silver. A marked decrease was also recorded in the gold won by dredges at Alder Gulch. There was an increase in gold bullion from the Barnes King properties, especially the Shannon mine at Marysville. Some bullion came from the new mill of the Bannack Gold Mining Co., at Bannack, in Beaverhead county. There was considerable activity in the Warm Springs district of Fergus county.

The output of silver decreased from 16,494,366 oz. in 1916 to about 12,788,000 oz. in 1917. In spite of the increased price, the value (\$10,358,000) was nearly \$500,000 less than in 1916. Nearly all the silver is derived from copper ore, the production of which decreased for the year.

The output of copper in 1917 was about 278,000,000 lb., a decrease of nearly 75,000,000 lb. The value of the output was about \$81,000,000, against nearly \$87,000,000 in 1916. Practically all the larger copper producers made a smaller output than during former years, especially the Anaconda and North Butte. On the other hand, there was a slight increase from East Butte. In March the Anaconda plants produced over 31,000,000 lb. of copper. Had this rate continued for the year, Montana would have had a largely increased copper output, but the industry was seriously affected by the closing of the mines and plants in July, August, and part of September. Shipments were made from the Tuolumne, Davis Daly, and Bullwhacker mines, and a good output came from the Butte & Duluth leaching plant.

The mine output of lead increased from 13,595,136 lb. in 1916 to about 17,000,000 lb. in 1917. The price of lead evidently stimulated work on many of the lower-grade lead mines. The lead concentrate from lead-zinc ore was less, however, on account of the decrease at the large zinc mines. At Troy, in Lincoln county, the new mill of the Snowstorm Mines Co. was producing both lead and zinc concentrate in July, and marketed considerable quantities of both products. The Valley Forge mine, in Lewis and Clark county, shipped much lead ore to Helena for concentration.

The output of recoverable zinc from Montana amounted to about 180,000,000 lb., against 229,259,075 lb. in 1916. Prices were lower in 1917, but the decrease was

also due in part to labor troubles and to a lawsuit between the two chief zinc-producers of the Butte region. During the first quarter of 1917 the Butte & Superior Mining Co. produced over 40,000,000 lb. of gross zinc, but it did not maintain this rate of production throughout the year. The Elm Orlu produced some ore but considerably less than in 1916. The rest of the output of the State came from the mines of the Anaconda company, the product of which is leached at Great Falls after being concentrated. Other shipments of zinc were made from the Snowstorm at Troy and the North Butte at Butte.

The dividends for 11 months amounted to over \$23,000,000. The principal dividend-payers were the Anaconda, Butte & Superior, North Butte, East Butte, Barnes King, and Butte-Bullwhacker.

Oregon Metal Production in 1917

A preliminary estimate of the production of metals from Oregon mines in 1917, compiled by Charles G. Yale, of the San Francisco office of the U. S. Geological Survey, shows a material decrease from that of 1916. The output of gold in 1916 was \$1,902,149, and the estimated output in 1917 is \$1,466,419, a decrease of \$435,760. The output of silver in 1916 was 231,342 oz., valued at \$152,223, and the estimated output in 1917 is 115,697 oz., a decrease of 115,645 oz. in quantity and \$58,046 in value. The output of copper in 1916 was 3,501,886 lb., valued at \$881,144, and the estimated output in 1917 is 1,508,639 lb., valued at \$410,349. A small quantity of lead was produced in 1916, but no production of this metal has been reported for 1917.

There are about a hundred productive mines in Oregon, and although two-thirds of them are placer mines, the larger part of the output of gold comes from the deep mines, and, of course, virtually all the output of the other metals. There were no important discoveries in any of the mining districts of Oregon in 1917, and no great increase in the output of any of the more productive properties. The entire output of ore from all the deep mines combined does not exceed 160,000 tons. Most of the placer mines are worked by the hydraulic system, but the three dredges now in use produce far more gold than all the other placer operations combined. The largest output of gold and other metals in 1917 came, as usual, from Baker county, which produces annually about 90% of all the gold mined in the State. Josephine county is next in production.

ZIRCONIUM minerals are chiefly used as a refractory material. The linear co-efficient of expansion of pure fused zirconia is 0.00000084. It is not only heat-resisting, but does not react as a flux to form slag. It is particularly desirable for laboratory refractory ware, such as crucibles, muffles, combustion tubes, resistance cores, and the like. Zirconia has a low conductivity, and refractory ware made of it must be thin-walled.

REVIEW OF MINING

TONOPAH, NEVADA

TONOPAH MINING.—TONOPAH EXTENSION.—TONOPAH BELMONT.
—WEST END CON.—JIM BUTLER.

The Tonopah Mining Co. continues to ship ore from the old dumps at the rate of 2500 tons per week to the plant at Millers. Commencing the first of the year about 150 tons of mine ore is being shipped to the Belmont mill daily. Arrangements have been made whereby the production of the Tonopah Mining Co. will be treated at the Belmont mill when the production does not justify the operation of the 100-stamp mill at Millers. During the past week 2400 tons of ore was milled, averaging \$10 per ton. At the Silver Top 32 ft. of development has been done and 42 ft. at the Sandgrass. At the Silver Top on the 340-ft. level the raise on the Burro No. 2 vein shows an increase in width and value. A raise has been started on the Upper Sandgrass vein from the 1140-ft. level of the Sandgrass. Last week's production was 2900 tons.—The Tonopah Extension Mining Co. shipped 24 bars of bullion valued at \$55,264. At the No. 2 shaft 90 ft. of development has been done and 169 ft. at the Victor. At the No. 2 shaft on the 1260-ft. level raise No. 450 was advanced 35 ft. on a 3-ft. face of ore. On the 1350-ft. level raise No. 567 continued in good ore and holed through into the level above. On the 1680-ft. level of the Victor the 1600 east drift advanced on a 4-ft. face of ore, while the 1600 west drift continues on a 6-ft. face of ore. The 1600 south cross-cut made 58 ft. of progress. The production the past week was 2350 tons.—The Tonopah Belmont Development Co. will operate its mill at capacity, as arrangements have been made to handle all the ore from the Jim Butler Tonopah Mining Co. and part of the Tonopah Mining Co. output. On the 700-ft. level east drift No. 721 on the Shoestring vein shows 1½ ft. of ore. Raise No. 8 from drift No. 721 is making good progress on the Shoestring vein. On the 800-ft. level east drift No. 8017 on the South vein struck a fault; but the vein was recovered. The west drift No. 8018 also struck a fault. On the 1100-ft. level raise No. 94 on the Western vein continues on a 1½-ft. face of medium-grade ore. Last week's production was 2255 tons.—The West End Consolidated Mining Co. shipped 40 bars of bullion valued at \$74,061. Driving to the west in drift No. 535 continues in a full face of excellent ore. Winze No. 534 is progressing in ore. Raise No. 814 has reached the foot wall of the vein. The output the past week was 1247 tons. At the Halifax Tonopah Mining Co. the 1018 cross-cut struck a small vein. Work has been suspended in the 1708 cross-cut awaiting the erection of a larger fan.—The Jim Butler Tonopah Mining Co. produced 746 tons of ore. On the 200-ft. level of the Wandering Boy raise No. 373 continues on a 3-ft. face of medium-grade ore. On the intermediate at the Desert Queen raise No. 654 uncovered ore.—The MacNamara Mining Co. shipped seven bars of bullion valued at \$11,700. Work in the raise on the 700-ft. level has been suspended for the present, and work in the west cross-cut has been resumed to allow for the exploration of the vein by raises. The production the past week was 517 tons.—With the completion of shaft repairs, work has been resumed in the raise from the 800-ft. level of the Monarch Pittsburg Mining Co.—The Montana produced 42 tons. and miscellan-

ous 61 tons, making the week's production at Tonopah 10,178 tons with a gross value of \$187,115.—During the past year the mines at Tonopah produced 485,000 tons of ore, having an approximate value of \$8,640,000. During the period \$1,870,309 was paid in dividends making the total dividends to date \$30,559,548.

MAMMOTH, UTAH

TINTIC STANDARD.—EUREKA LILY.—TINTIC DELAWARE.—ORE SHIPMENTS.—IRON KING.

At the Colorado Consolidated, which is a consolidation of the Colorado and Beck Tunnel mines, prospecting is being done on the 1100-ft. level, where a drift is being driven toward the south-east.—At the Zuma work is being carried on in the winze as well as in the cross-cut on the 500-ft. level. In both places the showing is satisfactory.—The shaft at the Copper Leaf Mining Co., which has been cutting through an exceedingly hard formation, is now in softer rock and much better progress is being made. The shaft is down 430 ft.—J. H. McNellis of Silver City, who is superintendent for the new owners of the Scotia property of West Tintic, states that the new machinery is now in place and that the development of the mine will be under way within the next week. It is the intention of the owners to thoroughly prospect the upper workings of the mine and if necessary go deeper with the main working shaft. The new equipment consists of a 12 by 12 compressor, a 30-hp. gasoline hoist, and a new cage. The shaft has been re-timbered.—The Tintic Standard is shipping two carloads of first-class ore daily. If cars can be secured the Standard will be able to ship at the rate of 100 tons of ore daily. In the newer workings north-east of the shaft, and also in the older part of the mine an immense tonnage of ore is exposed and the property promises to be one of the big producers of the district during 1918.—At the Eureka Lily mine, where the gas has been interfering with the work, a connection has been made which has relieved the situation. On the 1400-ft. level of the Eureka Lily drifts are now following two important veins and later raising will be started for the purpose of following a bunch of ore above the 1400-ft. The work is being carried on in a big mineralized area similar to that existing in the neighboring mine and it is hoped that only a little work will be needed to bring the mine into the productive stage.—The orebody of the Tintic Delaware is increasing with depth. This is being demonstrated by developments in the new workings, where carbonates are being replaced by sulphides in the bottom of the winze, which is now down 15 ft. For some time past the company has been developing a big body of high-grade lead-silver ore in the face of the adit and the work has demonstrated the deposit to be at least 30 ft. wide. Assays from the face ran up to 82½ lead and 8 to 10 oz. silver. It is planned to sink the winze to a depth of 50 ft. to prove the permanency of the orebody.—The total shipments of first-class ore from this district amounts to 169 carloads as compared with 118 for the previous week. The principal shippers were Dragon Consolidated 43 cars, Chief Consolidated 18, Eagle & Blue Bell 17, Iron Blossom 16, Grand Central 15, Centennial Eureka 13, Mammoth 11, Tintic Standard 10, Gold Chain 5, Empire Mines 5, Victor 4, Colorado

2, Scranton 2, other mines 8 cars, making the total 169.—A short time ago a trial shipment of iron ore was sent out from the Iron King property in the eastern end of the Tintic district and following the arrival of this ore at the smelter a satisfactory contract has been signed permitting the shipment of several hundred tons of the same character of ore which is now on the dump at the mine. The contract for the hauling of this ore between the mine and the railroad has been awarded to the Robertson Brothers of Eureka. There is an extensive supply of iron ore at the property and in the event of a railroad being built into that section the ore would be valuable to the company.

PLATTEVILLE, WISCONSIN

BLEND, GALENA, AND PYRITE PRICES.—ORE AND CONCENTRATE SHIPMENTS.

The month of December compares favorably with the records shown for other months of the year when operating conditions were far more favorable to the miner. Severe cold and heavy snow falls followed by windy spells obliterated roads and completely isolated many strong producers, making deliveries of zinc ore at times out of the question. To further cripple transportation facilities, at best none too good, for several months 20 engines were removed from the Galena division of the Northwestern Railway under orders of the War Department. This line gives immediate service to every mining district in the field and the carrying out of the order impaired the railway service so seriously that many small operating companies were compelled to suspend operations for the remainder of the winter. Price offerings while more nearly in adjustment with the price of spelter were regarded as unsatisfactory by miners because of the excessive cost of operating. Powder is now being sold at \$500 per ton; steel and all other essential supplies used in zinc-ore mining are from two to five times higher than they were two years ago, and labor also is much higher. There being no possible chance for lower prices of raw materials it follows that unless zinc-ore producers soon receive better prices for their ore many companies will be unable to continue and shut-downs are anticipated in every district of the entire field. Labor conditions showed considerable improvement through the month.

Prices for zinc ore were badly upset during the whole month, the base being given at the beginning of the month at \$62 per ton for top grades with the range down to \$57 for second and medium grades. Inquiry among buyers and sellers revealed a wide disparity in figures, the Linden district showing a base of \$58 per ton for 60% ore free from lime and lead. Cuba City operators reported the same base but gave additional figures of an interesting nature, 55% ore selling at \$44, 50% at \$40, 45% at \$34, 40% at \$30, 35% at \$26.50, and 30% at \$22.

Lead-ore producers persisted in their campaign of seclusion for the entire month, such ore as was sold coming for the greater part from the mines of the New Jersey Zinc Co. and being delivered to the company's own smelter at Palmerton, New Jersey. The regular quotation of \$75 per ton for 80% material did not apply, therefore, on the lead ore sent East and producers not so situated refused to sell their product at the prevailing quotation. Production was good considering the difficulties milling plants experienced during the greater part of the month from frozen intakes, mill reservoirs, and pipe connections. The reserve conservatively estimated at the beginning of the month at not less than 2000 tons all-lead concentrate was appreciably increased during December and yet operators courageously express the belief that better prices for ore are bound to develop before long.

Shipments of pyrites during the month were restricted because of the growing scarcity of cars for prompt loading of zinc ore. The increased handling of low-grade pyritic ores at

refineries is responsible for increased stocks of fine pyrites at separating plants and one firm alone reported a reserve stock in excess of 2500 tons. It would appear to the close observer that there is then held in the field at present not less than 5000 tons of this commodity. Such sales as were made were contingent upon contract arrangements and the price was not regarded as satisfactory.

Shipments of zinc ore from mines to refineries in the field and from mines to smelters direct and other ores made during December were:

Districts	Zinc lb.	Lead lb.	Pyrites lb.
Benton	24,036,000	402,000	286,000
Mifflin	6,318,000
Galena	2,610,000	186,000
Shullsburg	2,066,000	220,000
Linden	2,046,000	146,000	80,000
Platteville	818,000
Highland	712,000	60,000
Hazel Green	710,000
Dodgeville	600,000
Cuba City	408,000	2,298,000
Mineral Point	190,000
Totals	40,522,000	1,014,000	2,664,000

Shipments of the high-grade refined product from separating plants were:

	Lb.
Mineral Point Zinc Co.	6,142,000
Skinner Roasters (Wisconsin Zinc Co.)	6,014,000
National Separators	3,100,000
Linden Zinc Co.	674,000
Benton Roasters	568,000
Total	16,498,000

The recovery of mine run for the month amounted to 20,258 short tons; total net deliveries out of the field 13,953 tons. On distribution the Mineral Point Zinc Co. continued its hold on first place with receipts of 169 cars, 6297 tons; Grasselli Chemical Co. 137 cars, 5250 tons; Wisconsin Zinc Co. 100 cars, 3997 tons; National Separators 82 cars, 3468 tons; American Zinc Co. 44 cars, 1879 tons; M. & H. Zinc Co., La Salle 40 cars, 1599 tons; Linden Zinc Co. 24 cars, 889 tons; Illinois Zinc Co. 12 cars, 538 tons; Lanyon Zinc Co. 12 cars, 464 tons; Benton Roasters 9 cars, 379 tons; American Metals Co. 8 cars, 366 tons; and Edgar Zinc Co. 6 cars, 201 tons.

The principal operating firms in this field have had several mines under the one management for the past ten years. These groups are collectively the source of a major portion of the total recovery of zinc ore each month. For December the Vinegar Hill Zinc Co. delivered 106 cars, 4272 tons of zinc-ore concentrate. The Wisconsin Zinc Co. was a close second, delivering to the Skinner Roasters 100 cars, 4047 tons. The Mineral Point Zinc Co. was third, shipping from its own mines 96 cars, 3680 tons, to Mineral Point. The Frontier Mining Co. sent out 78 cars, 3019 tons, but shipments for December from this group of producers has been lighter than in several months preceding owing to bad roads and to the fact that several of its best producers are considerable distances from the railroad.

HOUGHTON, MICHIGAN

CALUMET & HECLA POLICY.—COPPER PRODUCTION.

The Calumet & Hecla and its ten subsidiaries, including Osceola Consolidated, La Salle, Isle Royale, Ahmeek, Allouez, Centennial, Superior, White Pine, Lake Superior Smelting, and the Lake M., S. & R. Co., comprising all of the mining, stamping, milling, and allied industries under the direction of first vice-president James MacNaughton, have announced a

continuation of the 10% bonus on the monthly pay and an additional bonus of 50c. per day for every man in their employ. This big pay has been in operation since last June and makes wages here higher than ever before. There is no doubt whatever that the Calumet & Hecla interests would have given the workmen a further increase in pay if they had any expectation that the Government would permit a raise in the price of copper above the 23½c. now in vogue, arbitrarily fixed

this district, 12,000 men in all. The other mining companies will follow the lead of the old Calumet, so that compensation to employees in the industry upon which this district depends will be as high for the coming six months as ever before and the production of copper for war purposes will be pushed as never before. It is a remarkable thing that every campaign for Liberty bonds, for Y. M. C. A. contributions, for Knights of Columbus work, and for Red Cross membership has met with enthusiastic approval and endorsement on the part of the miners of this district. There are no less than 30 different nationalities mixed in the cosmopolitan make-up of the Michigan copper district. Included are many technical alien enemies, Hungarians, Austrians, Croations, Germans, although only a comparatively small number of the last. They are employed in the mines. Their lodges have passed resolutions of loyalty to the United States, and nobody questions their loyalty. They are all members of the Red Cross and liberal contributors.

There is reasonable expectation of an increase in output for December for the Hancock Consolidated, owing to the installation of the storage-battery locomotive. **More trammers are needed.**—Electric locomotives are used at the Calumet & Hecla and subsidiaries as soon as they arrive; they are being operated on the longest underground hauls. Allouez is using five with satisfactory results. On the Osceola vein at No. 15 two are in use; 25 in all will be employed; Isle Royale is using three.—Superior already can see the end in sight. This is one of the smaller Calumet & Hecla subsidiaries, yet it has an interesting history in view of the fact that the company was the first one taken over for management purposes, when the policy of expansion was undertaken by the Calumet interests. At the present rate of output, 450 or 500 tons per month, the Superior has less than a year and a half in sight.—The Franklin continues to handle 1000 tons daily and is better than breaking even at the Government price for the output.

Practically all of this ore has a long tram haul, either by electric rope or compressed-air power.

Production of copper from the Michigan district will be 230,000,000 lb. for 1917. Exact figures will not be available for 60 days as smelters usually are from two to four weeks behind mills and mines in output. This estimate is based upon actual figures for the first eleven months of the year and estimates on December output. This figure is conservative and is just 5,000,000 lb. below the output for 1916. It is a remarkable record of efficiency, despite high costs, shortage of labor, and

HARPINGS MILLS FOR RE-GRINDING MILL-PULP

ELECTRIC HAULAGE UNDERGROUND

as stable for the metal used by the Government in munitions and for the Allies in their munitions. There was some hope that the price would be fixed at 25c. per pound as a number of the mines are operating at a close margin. As it is the continuation of present wages means the largest payrolls in the history of this district and is all the more satisfactory because the dividends to shareholders have been cut all the way from 50 to 300%, and in some of the mines they have been shut off altogether. The Calumet & Hecla announcement counts for more than one-half of the mining corporation employees of

inability to secure deliveries on necessities for mining, milling, and smelting operations.—No other copper-producing district in the world will come as near to normal as the Lake Superior district in 1917. This fact is a tribute to the highest class of copper-mining employees as well as the good management.—Calumet & Hecla alone will produce normal, 77,000,000 lb., compared with 76,762,240 lb. in 1916 and 71,030,518 lb. in 1915. Of the group of mines operated under the management of Mr. MacNaughton, as vice-president, the greatest increases are shown in Ahmeek and Isle Royale. Ahmeek's showing for this year is 28,600,000 lb., compared with a little better than 21,000,000 lb. in 1916 and 21,800,000 lb. in 1915. Isle Royale produced, in 1915, 9,342,000 lb., in 1916, 12,412,000, and this year 1917 the output will crowd 13,600,000.—Allouez will not produce up to the normal of 10,000,000 lb. Centennial likewise shows a falling off, and White Pine will be below 1916, but by only a small amount. Osceola Consolidated shows the greatest slump in output. It will show 16,300,000 lb., 3,000,000 short of normal in recent years. La Salle, while a small producer, shows a remarkable percentage of increase, rising close to 2,000,000 lb. this year. Superior clumps off nearly a million.—The total for the Calumet & Hecla interests for the year will be less than 3,000,000 lb. short of 1916. The Mohawk mine, one of the Stanton properties, will show 12,500,000 lb. Quincy production will exceed 21,000,000 lb., while last year this mine produced 21,065,612 lb. Wolverine figures for 1917 are 5,200,000 lb. Copper Range three mines show approximately 46,000,000 pounds.

While the production of copper from the three important south range producers, Champion, Trimountain, and Baltic, shows a falling off of 17% for the year 1917 compared with 1916, the respective totals being 46,000,000 and 54,747,498 lb., this is simply the result of intensive mining. Of this total the Copper Range company does not, of course, secure all, as the output of the largest producer, the Champion, is divided equally with the St. Mary's Mineral Land Co.—Quincy continues to turn out substantial mass copper with its regular run of ore. Regarding the larger masses that have been secured at the Quincy, there has been some doubt as to the ability of any smelter to handle an eight-ton chunk of solid copper. The Ahmeek mine frequently gets out masses that run 10 tons and only last week secured one that ran 11½ tons. This immense slab was cut from the solid sheet that has been one of the big Ahmeek assets for a long period. There was no difficulty in handling it in the smelter. The top is taken off the furnace and the copper oozed into the furnace much as a large piece of ice might be pushed into a water boiler. Cutting these solid slabs from the mine is a difficult job and requires men specially trained for the work. They use compressed-air machines that punch holes in a line a couple of inches apart across the solid copper slab; then the holes are packed tight with 100% blasting-powder and the powder is smeared across the whole row of holes. When it is fired it makes a rough break across the solid mass.—The output at Winona is running better than 500 tons per day with a steady improvement in the grade of ore extracted under the present system. The tributaries are paying the employees a premium over their regular wages for the higher-grade ore, the premium increasing directly with the proportion of copper.—While Calumet & Hecla, the old mine, shows slightly better output for 1917 than for 1916, it must be remembered that this figure includes the output from Tamarack, formerly listed as a separate property.—Within three weeks the additional turbine for the power-plant at Lake Linden will be in use and furnishing additional power to the main mine and subsidiaries as needed. More motors for hauling tram-cars underground are going into operation this month, some on the Osceola lode at the Calumet & Hecla, some at Isle Royale, and some at Ahmeek.—The Champion continues to be the marvel of richness in copper output of any property in the Lake Su-

perior district. Tonnage is maintained at normal and, while the proportion of copper is not going to show as high for 1917 as it did for 1916, the decline is small indeed. Some of the richest shoots of copper in this mine are just beginning to be opened.

COBALT, ONTARIO

CONIAGAS.—MCKINLEY-DARRAGH.—PETERSON LAKE.—CASTLE.

The silver-mining companies of Cobalt are beginning the new year under exceedingly favorable conditions, due to the high price of their product. Labor is comparatively plentiful and, although the cost of material and labor is considerably higher than a year ago, the high price of silver more than offsets the increase.—The annual report of the Coniagas company, which is expected to be issued within the next few weeks, will show a total of upward of 1,300,000 oz. of silver mined at a cost of a fraction over 21c. per ounce. The price of silver during the year 1917 averaged over 81c; it therefore follows that the net profit was 60c. per ounce.—Excellent results are being found at the 400-ft. level of the McKinley-Darragh. The method of re-grinding the tailing from the bed of Cobalt lake for treatment by flotation has been found unsatisfactory, and the new oil-flotation plant is undergoing some changes. The rod-mills are being replaced by ball-mills and with a return to warm weather the plant will be in shape to operate at full capacity.—The Peterson Lake company is considering the advisability of erecting a mill to treat the old tailing-dump of the Seneca Superior.—During December approximately 102 ft. of underground work was done at the Adanac. The zone to the north, the exploration of which geologists have recommended, will be reached within the next month, and the operation is commanding considerable attention.—The Mining Corporation and the Nipissing Mines Co. are maintaining a heavy yield and appear to be entering into a prosperous year.—The Castle Mining Co., owning property in the Gowganda silver area, has confirmed an arrangement with the Tretheway mine of Cobalt whereby the latter options the stock of the Castle property. The Castle company has 500,000 shares in the treasury, on which the Tretheway company has an option at 20c. per share, and some 265,000 shares outstanding are to be optioned at the same price. The property is adjacent to the rich Miller Lake O'Brien mine and is looked upon as a prospect of considerable merit.

At no time in the history of Porcupine were development operations being conducted on a more aggressive scale than at present. Work which during the boom days would have caused excitement now passes almost unnoticed. Notable among recent discoveries are those in the 800-ft. level at the Dome, in the 1000-ft. level at the McIntyre-Porcupine, and in the 1400-ft. level on the Millerton claim at the Hollinger.—The Schumacher company is gradually strengthening its position. The plan of the management to carry the main shaft from its present depth of 600 ft. to the 1000-ft. level will shortly be done. The new mill is in full operation and giving good satisfaction.—The Porcupine Crown is developing considerable ore at the 1000-ft. level.

The British American Nickel Corporation has under construction near Sudbury a new electrically-operated smelting refinery, which will have a capacity of 2500 tons of ore daily and a nickel production of 20,000,000 lb. per annum. The smelter will produce a matte carrying 80% copper and nickel combined, which will receive final treatment in the refinery.—The International Nickel Co. is constructing a new refinery at Port Colborne at a cost of \$4,000,000, which will be in operation in a few months. The initial capacity will be 15,000,000 lb. of nickel per annum, but it can be expanded in a few years to produce 60,000,000 lb. The new plant, according to the company, will be able to supply the needs of the whole British Empire.

THE MINING SUMMARY

ALASKA

(Special Correspondence.)—As a result of energetic prospecting by representatives of the Alaska Treadwell Co. during the summer, a molybdenite property situated about 80 miles from Wrangel has been bonded at Shakan. It is said to be extensive, although but little development has been done. Molybdenite is disseminated uniformly through the ore which also carries but a small amount of copper. Work of equipping and developing has already begun under Peter Johnson, formerly foreman of the Treadwell mines. A concentrating plant will be erected in the spring.

Treadwell, December 30.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—More than \$281,000 was distributed among the employees of the Copper Queen branch of the Phelps-Dodge Corporation, the Calumet & Arizona Mining Co., and the Shattuck-Arizona Copper Co. on January 7, in Bisbee and Douglas, this amount coming as bonuses in extra checks along with the regular pay checks for the last half of December. The miners employed by these companies in the Warren district received these checks, according to their term of employment, the amounts ranging from \$100 to \$30. All white employees on the surface and underground who had been continuously in the employment of the companies for one year or more received \$100, while those who had been in the service for six months to one year received \$50. The Mexicans employed on the surface continuously for one year or more received \$60, while those who had been in the service from six months to one year received \$30. The amount distributed to the underground and surface employees of the three companies in the Warren district totalled \$186,250, divided among the three companies as follows: Copper Queen, \$110,000; Calumet & Arizona, \$65,000; Shattuck-Arizona, \$11,250. At the Copper Queen and Calumet & Arizona smelters in the Douglas the same bonuses in the form of extra checks were paid the smeltermen, the same amounts being given as were received in the Warren district. The amount paid in Douglas totalled \$95,620, as follows: Copper Queen smelter, \$60,000, and Calumet & Arizona smelter, \$35,620. The wages paid at the mines and smelters are on a sliding scale, governed by the price of copper. With copper at 23½¢, the men at the mine receive \$5.35 per shift of eight hours, the time beginning at the collar of the mine-shaft. At the smelter the following wages are paid: furnace-men, \$5.35; machinists, \$5.60; converter-men, \$5.35 to \$5.60; crane-men, \$5.60; carpenters, \$5.60; common labor, \$2.30 to \$2.60. Announcement has been made that the companies are working out a permanent time-service bonus plan whereby continuous service will receive special consideration.

Douglas, January 7.

MARICOPA COUNTY

(Special Correspondence.)—Development on Empress Copper mine 15 miles east of Wickenburg has reached a depth of 400 ft. The vein is six feet wide and averages \$15 gold and 13½¢ copper. The mine is equipped with a 25-hp. hoist and a Sullivan-Foos 70-hp. engine; an electric pump to hoist 40 gal. of

water per minute is being placed on the 400-ft. level. J. P. Hutchinson of Phoenix is president and superintendent.

The management of the Carmelita Mining & Milling Co., with property in the Yuma range, is installing a gasoline hoist, Ritz air-compressor, hammer-drills, ball-pulverizer, three concentrating tables, and flotation process, all of which have been purchased in Los Angeles through the agency of the Kennard-Bierce Engineering Co. In the early days many thousands dollars were obtained by the arastra process. There are 17 claims in the group with more or less development upon each. J. A. Marx is superintendent.

Phoenix, January 10.

MOHAVE COUNTY

(Special Correspondence.)—The newly constructed concentration mill at the Red Cloud mine, 40 miles north of Yuma, is proving satisfactory. At 500 ft. the vein is 14 ft. wide and from this depth a cross-cut has been driven and a streak of high-grade ore found. The mill is of 300 tons capacity and is equipped with Hendy crusher, Eggleston ball-mill, and three Stebbins dry-concentrating tables. A product of 15 tons into one is produced. Cris Engle is superintendent.

Yuma, January 10.

A. G. Keating, consulting engineer to the Gold Mining Co., expects to commence shipping 100 tons of ore daily by March 1. It may require two weeks time to fill up the ore-bins of the old Gold Road mill, as they have from 1200 to 1500 tons capacity. By March 15 the mill should be treating 100 tons daily and bullion should be turned out 30 days later.—With December partly estimated, it can now be stated that the Oatman district produced only a little short of \$2,500,000 in gold during 1917. This is more than three times the production of 1916, and it exceeds by over \$500,000 the greatest amount ever mined in the district before. The year 1912 showed the highest previous production, according to Government statistics, the figures being 1,899,131.—The west drift from the 550-ft. level of the Gold Road Bonanza shaft has been driven 40 ft. from the shaft in commercial ore.—The close of the first year's operation of the United Eastern sees production maintained at the usual rate. The work of cross-cutting to the vein at the lower new level, 1090 ft. below the collar of the shaft, is about to begin; from 30 to 60 days may be consumed in opening the vein at this level.—Exploration of the Tom Reed Gray Eagle vein by means of a cross-cut from the 535-ft. level of the Aztec vein is now under way, but several weeks will be spent in driving this cross-cut, as the two veins are about 400 ft. apart.—At a depth of 350 ft. a station has been cut by the Record Lode Mining Co. and driving along the vein is now in progress.—The United Oatman adit has been driven nearly 800 ft. on the Ophir vein. A cross-cut to the west is also being driven.

Oatman, January 12.

PIMA COUNTY

(Special Correspondence.)—C. P. Reiniger has taken an option on the Orient and Copper Mountain group of claims from the Mile Wide Copper Co. The Orient group is on the northern side of the Tucson mountains and from the work that has been done at present the property has an encouraging prospect.—It is expected that development work on the Wake-

field-Bellmer claims in the San Xavier-Twin Buttes district will commence in a few days. A compressor has been erected and the head-frame is almost completed.

Tucson, January 5.

YAVAPAI COUNTY

(Special Correspondence.)—Work at the Jerome-Portland has been stopped. The men have been paid off, the pumps pulled out of the 500-ft. shaft, and some of the equipment sold. J. F. Miller & Co. of Jerome has placed an attachment totaling \$4100 on the real estate holdings of the Jerome-Portland.—It is reported that some ore has been discovered in the 1200-ft. level of the Blue Bell mine of the Consolidated Arizona Smelting Co., which is running higher in gold and copper than the ore on the 1600-ft. level. Recent development 2000 ft. south of the main shaft of the Blue Bell has opened a 24-ft. orebody at a depth of 75 ft. The company plans running a drift on the 800-ft. level southward to open the new strike at depth.—The Jerome Del Monte has suspended operations for the period of the War.—Shipments from the Jerome Verde have been suspended because it failed to renew the contract with the United Verde Extension to hoist 25 tons of its ore per day.

Prescott, January 7.

CALIFORNIA

ELDORADO COUNTY

The new Chili type of ball-mill is in operation at the Cincinnati gold quartz mine, situated 11 miles north-west of Placerville. On January 9 Jesse W. Taylor, of Fort Worth, Texas, accompanied by N. H. Burger, manager of the Cincinnati mine, and Burr Evans, mining engineer, made an examination of the mine and mill. The mine is opened and worked by a 300-ft. adit on the vein. At present ore is being stoped 50 ft. above the face of the adit from a 16-ft. pay-shoot of friable porphyritic material intermixed with particles and pieces of quartz, some of which contain high-grade gold-bearing arsenical pyrite. The entire cost of mining and milling the ore is less than one dollar per ton. The mill is operated by a 7-hp. gasoline engine. At present about 1½ tons per hour is put through the mill, but it is expected that this will be increased to two tons or better. Mr. Taylor is here to consult with Burr Evans with the view to interesting himself and Texas associates in the mines of this county.

KERN COUNTY

The miners of this county have formed an association to be known as the Caliente Creek Mining Association, which will meet at least once each month with the view of exchanging ideas and generally promoting the welfare of the mineral industry of the district. C. J. Stoneham, superintendent of the Copper-Jap mines, was elected chairman and Joe J. Carroll secretary.

NEVADA COUNTY

(Special Correspondence.)—An 8-in. shoot of gold quartz, assaying \$400 to \$500 per ton, has been struck on the 900-ft. level of the Norambagua mine. Prospecting has been in progress over a year at this depth, and arrangements are being made to develop the new shoot vigorously, in the belief that it is a branch of the main orebody. C. T. Green is superintendent.—Good ore has been found in the western end of the Golden Centre mine. A short run of the mill recently yielded \$35,000, according to reports by workmen. Several months ago the directors authorized sinking of the main 1000-ft. shaft to a depth of 2000 ft. and development of new ground is being pushed as rapidly as the water is cleared out. The mill is running steadily and the working-force was increased.—The California mine, near Rough & Ready, is reported to be developing well. It is owned by King C. Gillett and associates of Los Angeles and has been equipped with an

excellent plant.—The new vein uncovered in the Sultana continues to develop well, and the company is arranging for more extensive operations. The strike was made on the 1000-ft. level, and, according to reports, about the time the company was considering suspension of work.—Most of the equipment formerly operated at the North Star shaft of the North Star mine has been dismantled and numerous sections moved to the Central shaft. Use of the old shaft has been practically discontinued, but it is kept in repair for safety and ventilating purposes. The Central shaft is more than 6500 ft. deep and splendidly equipped. Development in the lower levels has been satisfactory.—The 40-stamp mill at the Brunswick Consolidated is running steadily; good ore is reported at several points. Much new ground has been added to the productive area in the past year.

Grass Valley, January 16.

SHASTA COUNTY

(Special Correspondence.)—The Mammoth Copper Co. has given up its bond on the Delta Consolidated gold mine, six miles west of Delta on Dog creek. The Delta Consolidated Co. has sold the steel rails on the 6-mile railroad from the mine to Delta to a lumbering company. The 300 tons of steel was sold for \$60 per ton, or more than it cost when the railroad was built in 1908.—The Central mine, at Old Diggings, which has been idle for years, is being opened up by A. A. Anthony, who has become the sole owner. He has given a lease to W. J. Thompson and James W. Holbrook, who are opening a good body of gold quartz.—A new body of ore has been uncovered in the New Year's mine at the Balaklala camp. The ore was found by a diamond-drill, and proved by a raise of 100 ft. from the old workings. The New Year's is a claim in the heart of Balaklala ground, owned by the Mountain Copper Co.—On December 24, fire destroyed a four-story bunkhouse and the boarding-house at the Balaklala mine. A full stock of provisions had been laid in for the winter. The loss was \$40,000. The management believes that the fire was of I. W. W. origin. Temporary quarters were soon provided. The mine was shut-down for only two days.

Redding, January 5.

The Mountain Copper Co. is doubling the capacity of its oil-fotation plant at Minnesota station, midway between the Iron Mountain mine and Keswick. It is not building a cyanide plant, as currently reported. The first flotation-plant was built three and a half years ago, and was doubled in capacity two years later. The enlarged plant will have a capacity of 1000 tons per day. Grading for the site is under way. The company is hampered for the want of material, as it can only get lumber and other building products at the pleasure of the Government. Work will be rushed as rapidly as war conditions will permit. The Mountain Copper Co. was the first mining corporation in Shasta county to use oil-fotation.

TULARE COUNTY

(Special Correspondence.)—During 1917, 1970 cars of magnesite, worth approximately \$2,400,000, was shipped from the Porterville district. As each car averages about 45 tons this makes a total of nearly 90,000 tons. Of this amount about 50,000 tons was of the calcined ore, worth approximately \$2,000,000. The remaining tonnage was shipped in the raw state and is valued at about \$400,000. Recently Federal authorities made a special request for data on the magnesite output of this district last year and the prospects for the amount available in the future. It is probable these data are being sought in line with other war preparations of the Government, as the output of the steel plants is in a large measure dependent on the output of magnesite. Owing to its highly refractory qualities magnesite is used extensively for linings of furnaces where a high temperature is maintained.

Porterville, January 9.

TRINITY COUNTY

The all-steel dredge of the Pacific Gold Dredging Co. has been running a month in its new position at the mouth of Coffee creek, four miles down stream from the mouth of Morrison gulch, where it was set up originally. The dredge has run smoothly from the day it was started. It will be remembered that the presence of large boulders was the cause of dismantling the dredge at Morrison gulch. No trouble from this cause has been found at Copper creek. Jack Harvey is the new superintendent of the dredge.

COLORADO

PITKIN COUNTY

(Special Correspondence).—On January 8 the stockholders of the Hope M. M. & L. Co. held its annual meeting. A canvass of the stock at the meeting showed that 67,715 shares were represented in person or by proxy. The following officers were unanimously re-elected: Charles O'Kane, president; James W. Hetherly, vice-president; Harold W. Clarke, secretary; John B. Stitzer, treasurer; and Charles O'Kane, Henry Turley, Albert Peterson, James W. Hetherly, and John B. Stitzer, directors. In his report to the meeting, Mr. O'Kane stated that during the past year the main adit had been advanced 1047 ft. at a total cost of \$15,275, making the average cost per foot \$14.58. The advance made in the breast varied during the year, some months showing better results than others. Following the advice of Messrs. Tower and Foote, who recently made an examination of the Hope properties, the course of the Annie cross-cut has been turned to due east. In making this turn, the drift cut 100 ft. of porphyry and a number of low-grade ore deposits, assaying as high as 22 oz. silver, 14% lead, 2% copper, and 22% zinc. The deposits, however, would not average as high and could not be handled profitably, but their presence is considered to be a favorable indication of richer bodies ahead. One large shoot was 75 ft. thick. The question of increasing the capital stock from 100,000 to 150,000 shares came up before the meeting and was passed without a dissenting vote. The additional capital is required to complete successfully the work now under way. The prospects of the enterprise are regarded as bright, and it is believed that large bodies of shipping ore will be found during the year.

Aspen, January 13.

TELLER COUNTY

(Special Correspondence).—The December production from mines of the United Gold Mines Co. was 66 cars, containing 2500 tons of an average value of \$21 per ton, and a gross bullion value of \$52,500. The production from the several properties was as follows: Trail mine, Bull hill, Anderson and Benkelman lease, 43 cars; J. L. Wilson lease, 12 cars; W. P. H. mine, Ironclad hill, shipped by the W. P. H. Leasing Co. of Cripple Creek, 7 cars; Bonanza, Battle mountain, operated under lease by the Granite Gold Mining Co., 2 cars. This ore assayed close to 3 oz. gold per ton. Wild Horse mine, Bull hill, 2 cars mined and shipped on company account. The Wild Horse company on December 20 paid a 1 cent dividend amounting to \$40,090 from accrued royalties paid into the treasury by lessees during the past year.—The output from properties of the Elkton Consolidated Mining & Milling Co., on Raven hill, for December amounted to 24 cars, or 850 tons, including dump shipments and the average value held close to one ounce gold, dump ore running as high as \$17.50 per ton. The company resumed operations during the month and shipped two cars of mill ore. George E. Collins of Denver, manager of the Mary Murphy mine, operating the Tornado mine of the Elkton company, shipped 4 cars of 1-oz. grade.—The Cripple Creek Deep Leasing Co. and its sub-lessee F. T. Caley, operating the Jerry Johnson mine on Ironclad hill under lease from the Jerry Johnson Mining Co., produced 455 tons of mill ore, averaging \$21 per ton, during December. Two cars from the

Caley lease, taken between 600 and 700 ft., brought \$57 and \$60 per ton, respectively.—Edwin Gaylord, of Cripple Creek, lessee on the Forest Queen mine on Ironclad hill, shipped 325 tons to the mill of the Golden Cycle Mining & Reduction Co. during December. The lessee is mining ore from a new shoot recently entered at the 600-ft. level east.—The Ocean Wave Mining Co. has pay-ore in the 400-ft. level of the new Ilurst shaft at the Ocean Wave and will commence to ship shortly.—An ore-house of 200 tons capacity with ore-washing tanks, and electrically lighted and heated, is under construction at the Lewellyn shaft on the Longfellow on the eastern slope of Bull hill. The property is owned by the Stratton estate and is leased to the Excelsior Mining, Milling & Electric Co.—The Vindicator Consolidated Gold Mining Co. shipped 200 tons of concentrate from its plant near the Golden Cycle mine last week for treatment at the Golden Cycle M. & R. Co.—The following dividends will be paid on January 10: Cresson Consolidated Gold Mining & Milling Co., 10c. per share, \$122,000; Golden Cycle Mining & Reduction Co., 3c., \$45,000; Granite Gold Mining Co., 2c., \$16,500.—A stockholders meeting of the Holliston Mines Co. has been called to consider the sale of the company's holdings in this district.—Stockholders of the Amazon Mining Co. will meet shortly to consider a proposition to dissolve. The holdings of this company, excepting small fractional claims, were sold some years ago and dividends paid from sale proceeds.

Cripple Creek, January 8.

IDAHO

SHOSHONE COUNTY

The third dividend of 5c. per share has been declared by the Hecla Mining Co. Until November last the company was paying 15c. per share monthly. Lower prices for metals and the heavy Federal tax have caused the reduction in dividend rate.—For the first three weeks of operation \$12,000 per week is the reported amount cleaned up by the Yukon Gold Mining Co., which recently began placer operations on Pritchard creek. The company is working the stream along which gold deposits were first discovered 35 years ago. Some large nuggets have been found. The company is a Guggenheim corporation which has secured the placer rights to 12 miles along the creek.—Net returns of \$225,921 were made by the Rex Consolidated Mining Co., at Wallace, from ore taken out during the first ten months of 1917, according to report of Raymond Guyer, manager. The mine was now idle in November and December.

No dividend has been declared. The records, when completed, will probably show that the profits have been expended in development work which has been expensive because of higher cost of supplies and labor. Resumption of work is expected at an early date.

MISSOURI

JASPER COUNTY

A concentrating plant is slowly being built by the Pleasant Valley Mining Co. on its lease about three miles south-west of Carthage. A good part of the equipment already is in place and more is being added, with the idea of having the plant complete by spring. The Pleasant Valley mine has been a good producer during the past year, operated merely as a hand-jig property. There has been a battery of nine of these hand-jigs, however, and a carload of ore has been made on the average and when things have been running well about every ten days. Operations are conducted at a depth of 100 ft., and the ground is well opened, there being two shafts in use. The concentrate is particularly satisfactory, being lead free, less than 1% in iron, and usually showing about 62% metallic zinc. The equipment at the plant, besides the hand-jigs, already includes a 90-hp. gas engine, a set of 30-in. rolls, a 14-in. crusher, and rougher and cleaner jigs are now being

built. The company is made up of J. H. Millard, H. H. Hoffman, and W. M. Graves of Carthage, and W. S. Pitt of Minnesota. Mr. Graves is superintendent. The company is operating this mine on a 20-acre lease of the Freer land, but it has in addition leases on the Douglas and St. Louis land, for a total of 100 acres.

LAWRENCE COUNTY

Recent drilling operations on the Grier land, west of Aurora, have been decidedly successful and it appears that a new richly-mineralized tract is about to be opened there. To date eight holes have been put down, five of which have showed excellent mineral. The last hole went into ore at 135 ft., and was still in it at 155 ft., indicating a 20-ft. face. The other holes showed ore at approximately the same level and for the same depth. The development work is in charge of J. H. Grier, owner of the land. After the drill prospect work is completed he intends to lease the property or develop it himself.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The Kewanas company is preparing for more comprehensive work in the northern and southern ends of the property. In the latter area connections have been made with the shaft of the Jumbo Junior, and a series of raises will be driven to prospect the main orebody. This has yielded some rich ore in the Jumbo Junior and ore of shipping and milling grade in Kewanas territory. In the northern section the more important work is proceeding 800 ft. north of the station.—Occasional shipments are being made from the Great Bend to the sampler of the Western Ore Purchasing Co. The product comes from the intermediate drift below the 160-ft. level, where two feet of \$100 ore accompanies the lower-grade material. From the 300-ft. level a drift is nearing the old Lockhart lease shaft, where milling ore was exposed when the lease ceased work. It is the plan of the management to eventually improve the small mill and operate the plant on the medium-grade ore in sight.—Free-milling ore assaying \$25 to \$90 per ton is being broken in an intermediate drift above the 100-ft. level of the Blue Bull. The vein occurs in the Pig claim and is narrow. A winze is down 125 ft. on this vein and driving from the 250-ft. level will start shortly for the purpose of developing ore at this depth.—Conditions at the Spearhead are improving. New work on the 250-ft. level has opened milling ore near the Wheeler shaft, and on the 910-ft. level north and south drifts are exposing milling-grade ore. From the east cross-cut on the 320-ft. level of the Cracker Jack drifts are prospecting two promising veins, showing scattered bunches of gold and silver-bearing ore.

Goldfield, January 14.

During November the Goldfield Consolidated produced 16,350 tons of ore at a profit of \$8380, and 14,459 tons of mill-tailing was treated at a profit of \$1981. Development to the amount of 858 ft. was performed at a cost of \$7.74 per foot.

LINCOLN COUNTY

(Special Correspondence.)—The Virginia-Louise Co. has placed orders for a large hoisting-engine and other machinery, and plans to start extensive operations in February. The management reports that considerable ore of profitable grade is exposed. The apex suit of the Prince Consolidated against the Virginia-Louise will be called in the Federal Court at Carson City shortly; both parties have retained eminent counsel. The Virginia-Louise recently brought suit for damages against the Prince Consolidated, alleging defendants had extracted ore unlawfully from its holdings. A decision by Judge Averill of Tonopah is expected soon.—The Raymond-Ely West Mining Co. is contemplating early resumption of activities. The property adjoins the Amalgamated-Pioche and

Greenwood mines, and the Greenwood Leasing Co. is endeavoring to secure a long-term lease. It is also reported that the company may operate extensively on its own account. Simon E. Bamberger, governor of Utah, E. A. Vail, M. B. Johnson, W. E. Harrison, and other Salt Lake capitalists are interested.—Much new work is proceeding at the Prince Consolidated, Amalgamated-Pioche, and other properties in this field. Late developments in the Prince Consolidated have been particularly encouraging, according to reports from the mine. This property has paid \$500,000 in dividends to date.

Pioche, January 13.

NYE COUNTY

(Special Correspondence.)—Milling and shipping ore have been developed on the 200 and 300-ft. levels at the Mayflower mine, and 1400 ft. north-west of the shaft a promising vein has been uncovered near the surface and opened to a depth of 35 ft. For the entire distance the vein consists of excellent milling ore, with portions carrying a high gold content. Arrangements have been made for extensive work on the first, second, third, and fourth levels, and from the third a drift will be extended to connect with the Starlight shaft. The mill is to be overhauled and improved, preparatory to steady operation. The management reports a large tonnage of profitable ore exposed. The property is owned by the Consolidated Mayflower Mines Co., of which W. J. Tobin is president and general manager.—The Sunset Mining & Development Co. is devoting particular attention to the Denver mine, where good ore has been opened on the 450 and 500-ft. levels. Abundant water for the mill has been secured and the management expects to operate the improved plant steadily this year. The holdings include the Denver, Tramps Consolidated, and Sunset groups.—The Pioneer Consolidated Co. is completing negotiations for a steady supply of power for the mill. A large tonnage of milling ore is in sight, but for several months the mill has been idle because of inability to secure economical electric power. Underground work has proceeded steadily and an extensive reserve of profitable ore is available for mining.—Leasing is active at the Montgomery-Shoshone, Indiana, and other properties. Arrangements have been made for early resumption of work on the New Year, Gold Bar, and several others. Many of the companies have been recently reorganized on an assessable basis.

Pioneer, January 5.

WHITE PINE COUNTY

(Special Correspondence.)—The Nevada Consolidated Copper Co. is running smoothly and turning out its usual tonnage of ore. Owing to the continued shortage of coal, fuel-oil is being used in the reverberatories and converters, though at a much greater daily cost than coal. The new railroad cut-off across Steptoe creek, which materially reduces the grade to the smelter, is completed. On account of the reduced grade the ore trains are hauling thirty 60-ton cars with the same locomotive and crew that formerly hauled 21 cars of 55 tons capacity.—The Consolidated Copper Mines shut-down its mill on January 1 and laid off about 200 men. It treated an average of 800 tons per day during the last month. The mill while metallurgically efficient was so poorly constructed that a thorough overhauling has become necessary, and, as there is a shortage of ore, the present time is convenient for making the repairs. But the main cause of shut-down is for want of ore to keep the mill supplied. For the past two months the Nevada Con. has mined and delivered at its mill from the Giroux Ora claim some ore continuously. It is planned to develop the mine while the mill is closed, and thus ensure a supply of ore when the repairs have been completed.—The county road has been changed from Keystone to the Coppermines property, which allows the company to put in a retaining dam to impound the tailing that has been running down by Robinson creek.—The Ward mine is shipping 25 tons

daily.—About 30 tons of 40 to 50% manganese ore is being shipped daily from a mine about seven miles south-east of Ely. There has been a dispute over title of part of the ground and an injunction against shipping was granted; but this was recently settled, by allowing one of the parties to mine and ship and deposit in the hands of the Court \$12 per ton until such a time as the title of the ground in dispute shall be settled by the courts.—The Muncy Creek property and the Lucky Deposit at Aurum, are continuing to ship copper ore. The county commissioners allowed the expenditure of \$100 to gravel and grade the road for trucks to a new spur put in on the Nevada Northern, about four miles south of Cherry Creek station, thus shortening the haul by about 30 miles.—Most of the lessees and outside work is closed for the winter.

Ely, January 3.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The production for the district for 1917 was 12,590 oz. gold and 732,581 oz. silver, or at present prices \$903,000.—The principal operating companies were the Socorro Mining & Milling Co., the Mogollon Mines Co., and the Oaks Co.—On October 26 fire destroyed the mine plant and upper portion of the Socorro mill. These are being replaced rapidly. A large part of the material is now on the ground and it is expected that the plant will be in operation early in the summer. Among the important developments of this company has been the cutting of a large body of good ore on the 1100-ft. level and new orebodies in the Johnson and Champion mines. The Mogollon Mines Co. completed its new 900-ft. shaft, has the drifts well started on lower development, and has largely increased the available ore-reserve during the year. Its 150-ton mill has run steadily to capacity.—The Oaks Co. has increased operations during the year. In March it took over the Maud S. mine, found ore within 30 days, and has been shipping daily to the mill since. In June the Deep Down mine was acquired, the Central shaft re-timbered, and a head-frame and hoisting-plant erected. Ore has been opened west of this shaft, which is being developed and shipped to the mill. Development and production have been continued at the Eberle and Clifton mines, the other two properties of the Central group, which are to be operated through the shaft on the Deep Down mine. Work was started on the Pacific mine in December and arrangements are being made to continue regular production.—The Deadwood shaft is being unwatered, material is being delivered, and this property will no doubt be in operation in the near future.—The main adit on the Iron Bar group is being driven to cut the ore found in the upper workings.—The year's operation at the camp has been favorable. While the fire at the Socorro mill reduced the production of the district to a marked degree the developed new ore in the deepest workings and the new properties opened point to a much increased production for 1918.

Mogollon, January 9.

OREGON

JACKSON COUNTY

(Special Correspondence).—Since the winter rains have set in, the copper mines in southern Oregon, which have long wagon-hauls, are reducing their shipments of ore and are developing for record shipments next season. The Blue Ledge has 60 men employed and is shipping 1000 tons per month, while the Queen of Bronze has 40 men employed and is shipping 1200 tons per month, and the Waldo has quit shipping and has 10 men employed developing.—O. C. Runnels of Seattle, representing people of that city, has purchased the Utah group of quicksilver mines, 12 miles north of Gold Hill, as well as the Samuel Bertleson group of adjoining claims, and intends to combine these properties. These mines are contiguous to the Chisholm group of mercury mines, which is

equipped with furnaces. Machinery is being ordered to equip these new mines and representatives of several machinery companies are on the ground to arrange the final details.—Tony Ross and Lawrence Witsette of Gold Hill, who have a lease on the Reynolds copper mine six miles west of Waldo, are making considerable progress in development work. Recent assays show that the copper ore near the surface runs 10 oz. in silver per ton and some gold. This property is eight miles west of the Queen of Bronze copper mines and within half a mile of the Grants Pass-Crescent City highway. Five veins, from 5 to 20 ft. wide, run through the property at an elevation of 2600 feet.

Gold Hill, December 31.

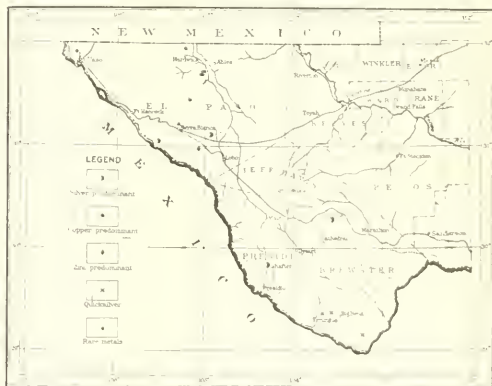

(Special Correspondence).—O. C. Runnalls of Seattle, who recently acquired the Utah and Bertleson groups of cinnabar mines, 12 miles north of Gold Hill, for Seattle investors, will incorporate a company with a capital of \$600,000 and equip the properties with a mercury-reduction plant of 100 to 200 tons capacity. A power-line will be erected from the C-O Power Co.'s line in the Beagle district, five miles from the mine, and electric power will be used in operating. Samuel Bertleson of Beagle will be the local manager temporarily.

Gold Hill, January 5.

TEXAS

BREWSTER COUNTY

(Special Correspondence).—The Marfa & Mariposa Mining Co. has lately sold all its interests, mine, two 12-ton Scott furnaces, and about 2000 acres of cinnabar-bearing land. This

PART OF TEXAS

mine was discovered by Thomas Golby and G. H. Normand in 1897 and began to produce quicksilver in 1899. For several years it turned out about 400 flasks per month and paid over \$500,000 in dividends. The rich ore was found between the massive lime and an impervious clay, in one instance a 'kidney' was taken out just below the surface of the ground weighing 15 tons; many smaller 'kidneys' were found. In 1909 these rich surface deposits began to be more difficult to find and as no work had been done on the low-grade fissure veins in the massive limestone, in which the cinnabar was found in banded calcite, it was found impossible to run at a profit at the low prices then prevailing, so the mine was closed. In 1916 it was leased to the late superintendent, A. Newell, was re-opened, and has been steadily producing ever since with a small force of men and only one furnace operating. The Chisos mine is producing 500 flasks of mercury per month. The Big Bend, the Texas Almaden, and other mines are also producing quicksilver and the prospect for a still larger output of mercury is encouraging.

Terlingua, January 7.

CANADA

BRITISH COLUMBIA

The Highland Valley Mining & Development Co. will erect a hoist and air-compressor, and the capacity of the mill will be increased to 100 tons per day. In November the mine produced 70,000 lb. of copper in the form of a concentrate running 22% copper. With the added improvements it is estimated that wide and assays from 4 to 5% of copper.—The orebody struck on the Noonday mine recently has been followed for 40 ft., according to a report from Kaslo. It has a width of eight feet throughout. More than a foot of it is of a shipping grade, the remainder being concentrating. The strike was made at a depth of several hundred feet, at a point near the line of the Noonday and the Consolidated Mining & Smelting properties. The drift is proceeding into the Noonday from the direction of the Consolidated.

MEXICO

(Special Correspondence.)—During the month of December there was shipped through the Douglas port of entry 317 cars of Mexican-mined ore and concentrate, having an estimated value of \$2,785,000, as compared with 354 cars in November having an estimated value of \$2,873,600. The number of cars, points of origin, and tonnages are as follows:

Origin point	Cars	Tons
Nacozari	255	10,207
La Estrella	18	731
El Tigre	14	497
Promontorio	11	404
El Rosario	5	180
Belen	3	131
San Pablo, Ultima Chanza, La Caridad, Esperanza, Cuicuilá, Archipiélago, Santa Rita, Las Chispas, San Francisco, La Fortuna, and La Reforma, one car each.....	11	277
Total	317	12,490

The shipments from Nacozari were composed mostly of copper-silver concentrates from the concentration plant of the Mochtezuma Copper Co., which is situated at Nacozari. These concentrates were treated at the Copper Queen smelter at Douglas. The shipments from El Tigre were composed of concentrates from the concentration and oil-flotation plant of the Lucky Tiger Combination Co., the shipping point being the station of Esqueda, on the Nacozari railroad. These concentrates are treated at the El Paso smelter. The Promontorio mine is owned by the Phelps-Dodge Corporation, the ore carrying principally copper and silver. The mine is situated in the district of Mochtezuma, about 100 miles south of Nacozari, and the ore is shipped to that point by wagon and mule-back transportation.

Nacozari, Sonora, January 7.

SPAIN

PROVINCE OF VIZCAYA

At a joint meeting of the shareholders of the Altos Hornos de Vizcaya and those of the Hulleras del Turón an agreement was reached for the purchase by the Altos Hornos of the coal mines in Asturias, now owned by the latter company. This purchase follows a lengthy examination of the Turón coal mines, and extensive tests of the coking quality of the coal. The price is said to be 20 million pesetas, or approximately \$4,000,000, which is six times what the mines would have brought three years ago, but the great iron and steel operations of the Altos Hornos is relieved from uncertainty of supply and exorbitant costs of its needed fuel by taking over these Asturias coal properties, even at such a figure. The mines of Turón produced 240,000 tons of coal in 1916, and has developed at a faster rate than any other coal property in Spain.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

WILLIAM W. MEIN is here from New York.

COOPER SHAPLEY, of Bishop, is in San Francisco.

W. L. PAYNE has arrived here from Moscow, Russia.

D'ARCY WEATHERBE is expected here from Shanghai, China.

JOHN J. CROSTON is Lieutenant in the 27th Regiment Engineers.

S. C. BULLOCK is Captain in the Royal Engineers, British Army.

J. POWER HUTCHINS is due in San Francisco from Petrograd, Russia.

F. H. HAYES is Captain and Adjutant, First Arizona Infantry.

WILLIAM HUTCHINSON is in the Canadian Forestry battalion, in France.

SCOTT TURNER is in San Francisco, on his return from Peru to Toronto.

HAROLD RICKARD is Lieutenant in the Royal Engineers, British Army.

DOUGLAS CLARK is with the Seoul Mining Co. at Tul Mi Chung, Korea.

GEORGE W. COFFEY is Lieutenant in the Engineer Officers Reserve Corps.

J. W. MOULE is now metallurgist at the Great Cobar smelter, New South Wales.

L. C. PARKER, formerly at Butte, is now mining in Shasta county, California.

DEE W. MINIER, First Lieutenant in the 112th Engineers, is now at Los Angeles.

JOHN MCCOMBIE has been appointed manager for the Waihi Extended, New Zealand.

A. F. DUGGLEY is with the 27th Engineers, and is stationed at Camp Meade, Maryland.

W. H. LANAGAN has been promoted to Major in the Engineer Officers Reserve Corps.

EDWARD WALSER, of Butte, Montana, was in San Francisco this week on his way to Denver.

A. B. ROGERS, of Denver, has assumed the management of the North Star mine at Yuma, Arizona.

E. V. DAVELER, superintendent of mills for the Alaska Gold Mines Co., Thane, Alaska, is in San Francisco.

F. S. NORCROSS JR. has passed the examination for a commission as Captain in the U. S. Engineer Corps.

HUGH R. VAN WAGENEN is at Tonopah working on the suit between White Caps and Manhattan Morning Glory.

E. J. CARLYLE and M. R. HULL have opened an office for the Sisser copper company, operating in Russia, at Salt Lake City.

WILLIAM ROBERTS, of Penaporth, Cornwall, has gone to Mexico as manager for the Avino Mines Ltd. at Gabriel, Durango.

C. H. MACNUTT, Lieutenant in the Canadian Engineers, has been transferred from the firing-line to an important home service in England.

A. C. LWSOON has been elected chairman of the San Francisco section of the A. I. M. E., with W. H. SHOCKLEY as secretary and treasurer.

W. A. MILOCHE has been appointed to the Engineer Officers Training School from Camp Kearny, California, to Camp Lee, at Petersburg, Virginia.

SAMUEL W. COHEN, general manager for the Crown Reserve Mining Co., Ltd., has returned to Montreal after a six weeks trip in California and Colorado.

THE METAL MARKET

METAL PRICES

San Francisco, January 15	
Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	17.00
Antimony (wholesale), cents per pound.....	14.75
Electrolytic copper, cents per pound, in carload lots.....	23.50
Electrolytic copper, cents per pound, in small quantities.....	24.67 1/2
High-lead, cents per pound.....	7.00—8.00
Platinum, soft and hard metal, respectively, per ounce.....	\$105—113
Quicksilver, per flask of 75 lb.....	\$125
Spelter, cents per pound.....	10.00
Zinc-dust, cents per pound.....	20.00

ORE PRICES

San Francisco, January 15	
Antimony, 45% metal, per unit.....	\$1.00
Chromite, 34 to 40% free SiO ₂ , 8 1/2 to 9 lb. California, per unit, according to grade.....	\$0.60—0.70
Chromite, 40% and over.....	\$0.70—0.80
Magnesite, crude, per ton.....	\$8.00—10.00
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mo quoted on the basis of 48% material.	
Tungsten, 60% WO ₃ , per unit.....	26.00
Tungsten ore remains firm.	
Molybdenite, per unit Mo.....	\$40.00—45.00

EASTERN METAL MARKET

(By wire from New York)

January 15—Copper is quiet and unchanged at 23.50c. all week. Lead is quiet and higher at 6.70 to 6.90c. Zinc is inactive and steady at 7.87c. all week. Platinum remains unchanged at \$105 for soft metal and \$113 for hard.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date		Average week ending
Jan. 9.....	90.12	84.70
" 10.....	90.12	85.70
" 11.....	90.12	85.38
" 12.....	90.12	86.02

June 1916.....	49.03	65.04

Silver has undergone very little fluctuation during the past week and is now quoted at 91 1/2c. per ounce.

Samuel Montagu & Co. says: The Transvaal gold output for November amounted to £3,070,426, as compared with £3,326,253 in November 1916 and £3,191,279 in October 1917. The total up to the end of November is only £35,255,282, compared with £36,135,229 during the same period in 1916.

The Shanghai exchange continues firm; possibly there is some connection between this strength and the approach of the Chinese New Year, which falls on February 11. On December 12 the official rate, 4.3d., the high rate received in recent years, approximates within a fraction the point at which silver could be shipped at a profit from San Francisco, but it should be remembered that silver transactions of this character need a license from the United States government. No fresh news has come to hand with regard to the projected purchase by the British and American governments, pending some definite details the market remains somewhat inert. It is proposed in France to demonetize silver coin bearing the effigy of Napoleon III crowned with laurel. The object in view probably is to extract the large quantities of such coin now hoarded, to re-coin pieces with a new design from the metal that is now available, and then issue the new coins as required. It is anticipated that by this means the need of purchasing fresh silver for coinage will be reduced.

LEAD

Lead is quoted in cents per pound, New York delivery.

There is no market in New York at the present moment for spot tin as no material is to be had at any price. Straits tin for shipment is quoted at 64 to 65c. while Banca tin, of which some is said to have been sent by express overland, is reported sold at 70c. per pound. However, the tin position is exceedingly difficult at the present moment and is practically a sellers' market.

Charles H. Bly says: The past week has been a busy one for the new year in tungsten ore and while most of the business was done in the grade ore, some high grade ore was sold at prices ranging from \$23.50 to \$25.00 per unit. The business in the tungsten ore market was quiet, although a good many lots which had been on the New York market for some time. The business, however, still meets with a lot of difficulty as it is hard to get ore sold on account of freight conditions in New York. As soon as shipments can be made with more regularity the business in tungsten should improve. Business was also started during the past week in molybdenite at a negotiated price of \$7.25 to \$7.50 according to grade. The tin and molybdenite markets now exist at first hand decline to make prices bettering that molybdenite the market will recover and material in second hands which can be had at 60-cents is not sold as buyers are prominent by their absence.

Manganese remains unchanged with the January schedule at \$1.20 delivered at the furnace for high grade ore. High grade chrome ore is still quoted at 10c. per unit, for shipping and for sale. Business has been reported.

The molybdenite market remains practically the same. A few inquiries, however, are in the market for small lots but the market has not shown the expected strength as yet.

California virgin mercury has dropped to about \$120 per flask of 75 lb. net while Mexican is quoted around \$115 for spot material.

Eastern Metal Market

New York, January 9.

The markets are all quiet and do not present any unusual features. Readjustment of accounts and the appraisal of stocks explains in part the dullness.

Copper is moderately active at the Government prices.

Tin is nominal, high, and still scarce.

Lead is firmer and stronger in tone at higher levels.

Zinc is again lifeless at unchanged prices.

Antimony refused to be excited and continues to sag.

Unprecedented low temperatures in the East and blizzards of large proportions in the West have seriously interfered with pig-iron production, and have added to the difficulties already present because of railroad congestion. Some steel plants are operating at only 50 to 75% of capacity. The industry has never been so badly crippled. December pig-iron output was low (only 2,882,919 tons) or 92,997 tons per day, against 3,205,794 tons, or 106,859 tons per day, in November. The relation of supply and demand is secondary to Government price-fixing. An important question for buyers to consider is: If there are new prices April 1, will they apply to deliveries carried beyond that date, even though contracted to be delivered in the first quarter? They will, according to reliable sources.

COPPER

Government demand for copper is reported as becoming larger in volume as the weeks go by and this is also true of that of the Allied governments. Domestic manufacturers, working more or less directly for the Government, are also buying more metal. There seems to be a good demand from wire mills. The volume of all of this business is large and it is going at the regulation Government prices of 23.50c. for carload lots or more, and at 24.67½c. for less than carload lots, with every prospect of sufficient copper to meet all needs. Nothing more is heard of a change in the fixed level, and it seems assured that this subject will not come up again for some time. The jobbers report that they have frequent requests for copper at 23.50c. because the conditions under which they have taken certain Government orders stipulate that they must not pay more than 23.50c. for the copper they use. In such cases, the jobbers have had to refuse the business at less than 24.67½c. How such small orders are being handled no one seems to know unless the Copper Producers' Committee is taking care of just such small business on Government account. One jobbing dealer in New York states that he is doing a good business at 24.67½c. for general consumption. There is some talk that the fuel scarcity, combined with railroad congestion, may lessen output at refineries, but only time can answer this. The output of refined copper from primary sources in 1917, according to preliminary figures of the U. S. Geological Survey, just issued, is estimated at 2,362,000,000 lb., compared with 2,259,000,000 lb. in 1916, and 1,615,000,000 lb. in 1913.

TIN

A small lot of Straits tin was sold at 80c., New York, on January 2 but this is the only transaction noted in many weeks. There is no spot market, and quotations are entirely nominal at about 85c., New York, with no prospect of the acute scarcity being relieved in some time. There has been in the last two weeks a big decline in the London market which reached its climax about January 3, which probably explains the 80c. sale referred to. There is no other explanation. Since then the London market has advanced suddenly, due perhaps to permit negotiations, though the real reasons are not known here. On January 7 the London quotations for spot Straits was £282 per ton, as compared with £272 on January 3 and £209 10s. on December 21. Recently in New York a few buyers

got their courage up and went into the market, buying in two days an estimated tonnage of 200 to 300 tons of futures, mostly Straits, with some Banca and Chinese included. This is a decided improvement over recent weeks. The rank and file of purchasers, however, are still refraining from purchases, preferring to wait until conditions are more settled. Arrivals to January 3 inclusive have been 460 tons.

LEAD

After many weeks of practically one level the lead market has advanced, due to a change in the quotation of the leading interest. The American Smelting & Refining Co. on January 3 raised its New York price ¼c. per lb. to 6.50c., New York. This was followed on the next day by the independents who advanced their price to 6.70c., New York, or 6.55c., St. Louis. The reason for the advance by the Trust is generally conceded to be that because Government purchases are being settled on the average St. Louis price and because its New York price was lower than the St. Louis, an advance was proper. The result of the action has been to make the tone of the market stronger and firmer. Business, however, has been only of moderate proportions, due to a lack of sellers as much as anything. Spot lead is held at 6.75c to 7c., New York.

ZINC

The market has relapsed into its former lifeless condition and it is not strong. The prevailing quotation for prime Western for early delivery is 7.62½ to 7.75c., St. Louis, or 7.87½ or 8c., New York, at which levels a little business has been done, but it is not likely that the larger producer would be willing to seriously consider a large inquiry at these levels. It is understood that the 4000-ton inquiry for grade C for the Army's use has not been let. The bids on these were believed not to have been numerous, but it is the impression that the Government has been able to secure all it needed at the quotations obtained on the 1000-ton purchase for the Navy, referred to in previous letters. The expectation is that the U. S. Geological Survey's preliminary statistics on the 1917 output of zinc, which will be out any day now, will show this to have been not very different from the 667,456 tons produced in 1916. Exports are estimated at slightly in excess of those for 1916 when there were 206,000 tons. One estimate puts the deliveries into consumption at about 400,000 tons in 1917, which is 58,000 tons less than in 1916, but larger than 1915 or any other previous year. Although weather and railroad conditions are interfering with the receipts of metal from the West, stocks seem sufficient here.

ANTIMONY

The spot market is lifeless at 14.50 to 14.75c. per lb. duty paid, New York. Considerable competition is anticipated for an expected Government inquiry for 200 to 300 tons for March-April delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is held at 36 to 38c., New York, for early delivery with the market quiet. Sales are reported at 37 to 38c. The Aluminum Company's contract price for ingots so far for 1918 is stated as unchanged at 38c. per pound.

ORES

Tungsten: Both high and low-grade ore has been sold at \$24.50 to \$25 per unit in 60% concentrate in the last week. Business is being more or less interfered with by the weather and freight congestion. Ferro-tungsten is obtainable at \$2.35 per lb. of contained tungsten.

Molybdenum and antimony: Molybdenite is unchanged at \$2.25 to \$2.30 per lb. MoS₃, depending on the grade and some sales are reported at these levels. Antimony is unchanged with the market nominal.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

A NEW LEYNER MACHINE

The modern hammer-drill, using hollow drill-steel and air or water to expel the cuttings from the drill-hole is now the rule rather than the exception in practically all rock-drilling operations. There is considerable carelessness in the matter of keeping the hole in the drill-steel open. Wholly or partly plugged steels prevent proper functioning of the drill, the drilling-speed is retarded, water-tubes are bent or broken, and time is lost in tinkering or, as often happens, the drilling

provided to regulate the distance to which it is desired to have the pin penetrate. The standard punching-pin is $\frac{3}{8}$ in. diam. for a distance of 2 in. from the end, and $\frac{1}{2}$ in. for the remainder. The operation of the machine is controlled by a single lever moving in a T-slot. A downward movement clamps the steel, and a further side-movement operates the punch. The operation of the control-lever locks the clamp-jaws before the punch can be brought into action. In like manner the punching-device must be in a neutral position before the clamp-jaws can be opened. This safety feature prevents action of the punch before the steel is firmly clamped and in perfect alignment. It will be noted that all moving-parts are protected from dirt, grit, and damage, by tight-fitting covers; likewise the operator is guarded from injury. The Leyner shank and bit-punch occupies a floor-space 22 by 44 in. and weighs 400 lb. A plank support is the only foundation needed.

LEYNER SHANK AND BIT-PUNCH

gang is idle while someone makes a trip to the shop after another drill-steel or water-tube. To relieve this condition the Ingersoll-Rand Co. has developed and is placing on the market, as an auxiliary to the 'Leyner sharpener,' a new device, the Leyner shank and bit-punch. This compact and simply constructed machine consists principally of a cast-iron pedestal, at the top of which are bolted the clamping and punching-cylinders and apparatus. The drill-steel is clamped by two jaws brought together by the movement of a pinion, operated by the clamping-cylinder through the medium of a rack on the extended piston-rod. The heat-treated steel punching-pin is attached to the piston of a punch-cylinder, and in such manner that it may be readily removed should occasion require. The front head of the punch-cylinder is provided with a clearance space around the punching-pin so that, on the extreme reverse stroke, air is exhausted against the heated pin, effectually cooling it. The maximum stroke of the punch is 6 in. An adjustable stop for the drill-steel is

ALBANY GREASE

Fifty years ago the firm of Adam Cook's Sons was incorporated as the Albany Lubricating Compound & Cup Co. in Albany, New York. The firm was founded by Adam Cook. The history of Adam Cook's Sons is the story of the growth of 'Albany Grease' and that is the record of grease lubrication from its infancy up to the present time. Prior to 1868, oil was the only practical medium by which lubrication could be secured on mechanical work. Lubrication in those days was costly and not efficient. The stumbling block in oil lubrication was the exceedingly great amount of attendant waste. The trouble was the inability to keep a liquid in some sort of a container so that it would not run off or leak out until it had accomplished its object and until every lubricating atom in it was consumed in service. Adam Cook realized that it was highly improbable that any device could be secured to give the needed relief, and he selected the lubricant itself as the thing to be improved. 'Changed,' is the word that expresses what Adam Cook did, for in 1868 there was put on the market Albany lubricating compound, now familiarly known all over the world as Albany grease. That name was given to Albany lubricating compound by the engineers of the country. The point was willingly conceded, and soon the compound was re-christened 'Albany grease,' and has ever since been known by that name.

A small plant in Albany was erected at first, but within four years this became too small. In 1872, larger quarters were secured on the river front at 231 West street, New York City. Here was thought to be ample room for growth, but soon these quarters were outgrown, and in 1881, only nine years later, the business was moved again to larger quarters at 313 West street. As the business grew by leaps and bounds additions were made to the original building by the purchase of neighboring warehouses and the Albany plant soon ran through the entire block from West to Washington street. Despite the room available, the need of concentrated methods of production and the assembling of all departments presently made itself felt. In order to take advantage of the latest manu-

facturing methods, it was decided to bring into closer relations all the various departments of the business under a single roof. After a stay of 30 years, the West and Washington street plant was abandoned, and the modern commodious plant at 708-10 Washington street was placed in service. 'Albany grease' is celebrating its 50th anniversary and is receiving congratulations from an army of satisfied users.

NEW ORGANIZATION FOR LITTLE GIANT

After an existence of nine years as a department of the Chicago Pneumatic Tool Co., the motor-truck interests of the company were, on January 1, taken over by a new organization known as the Little Giant Truck Co. From small beginnings the motor-truck department of the Tool company had grown to such proportions that a separate organization became absolutely necessary. The growth was particularly marked during the past year. A good staff of active dealers, eager to ally themselves with a 25-year old concern, a complete line of motor-trucks from one to five tons capacity, the Duntley gas generator which permits the use of cheap fuels such as kerosene and distillate as an exclusive feature, all these have helped to build up the prestige of the 'Little Giant' truck and to practically double the volume of business during 1917. The factory at Chicago Heights has an amount of business on its books that will take months to complete, notwithstanding the increased facilities for manufacturing that recently have been added. At present, slippery streets, the rising cost of horse-flesh and horse-feed, the shortage of labor, the unqualified endorsement of motor-trucks by the railroads in the present traffic congestion, are factors which induce optimism for the motor-truck business. The Little Giant Truck Co. is owned and controlled by the Chicago Pneumatic Tool Co., and the officers are the same: W. O. Duntley, president; W. B. Seelig, secretary; L. Beardsley, treasurer; with T. J. Hudson, sales manager. The headquarters will remain in the Little Giant Bldg., 1615 Michigan Ave., as heretofore.

FREE INSTRUCTION IN TRACTOR AND MOTOR-TRUCK DRIVING

How to use gas tractors with the greatest efficiency, and how to lengthen their lives and increase their usefulness by keeping them in perfect repair, such is the object of the 'short course' to be given by the University of California at the Experiment Station at Riverside from February 11 to 16. The University points out that, with the present limited supply of labor, it is the patriotic duty of every owner of a tractor to see that his tractor does as much work and as good work as possible. Proper training for the operator and proper care of the machine are of the first importance. This tractor course will be similar to one recently held at Davis, where 184 people learned how to operate and to repair tractors. There will be lectures, illustrated with charts and models, on gas-engine principles, fuel, carburetors, magnetos, timing, adjustment, and all details. Instruction is given by experts from various factories as to the construction, repair, and operation of the eight or more makes of tractors to be used. There will be field demonstrations on the operation of tractor-machinery and tests of horse-power will be made. Each student will have an opportunity for practical work in soldering, pipe-fitting, carburetor-adjustment, bearing-adjustment, ignition-timing, belt-lacing, and the like. The course is open only to those who can show that they will be able to make definite use of the knowledge gained. The only expense will be a registration fee of one dollar.

C. P. Coleman was elected president of the WORTHINGTON PUMP & MACHINERY CORPORATION, at a meeting of the board of directors, held on Monday, December 31, 1917.

COMMERCIAL PARAGRAPHS

GUSTAVE A. OVERSTROM and CHARLES V. CRAIG have made a contract for handling the 'Universal' concentrator, covered by application for patent, serial number 132,357. Mr. Craig undertakes to manufacture and sell the machines, becoming half owner of the patent right.

'Caterpillar Times' for December last, tells of the extraordinary feats performed by the many types of caterpillar trucks and tractors produced by the HOLT MANUFACTURING CO., INC., of Stockton, California. One achievement is plowing up 35 to 50% grades in the State of Washington. Other machines are shown engaged in threshing grain, harvesting beans, logging, and doing work in road-building.

'STANDARD OIL BULLETIN' for December gives praise to Japan in a look across the Pacific for commercial expansion; tells the story of Tom Orr's Ford car, the oldest active representative of this brand in California; a pleasant review of certain mascots; and then offers an interesting discussion of viscosity of oil and the critical velocity in pipeline transportation. There is also a list of the employees of the Standard Oil in California who have joined the colors.

THERE was placed in service in December for the Cerro de Pasco Mining Co., Peru, a 3000-kw. hydro-electric plant. The company already had one plant of 9000 kw. In December the Homestake Mining Co. started, at Spearfish, South Dakota, a 4000-kw. hydro-electric plant, thus duplicating the former plant. Frank G. Baum, consulting engineer of San Francisco, had charge of the engineering construction of both the above plants, and has under way a 1000-hp. hydro-electric plant for the San Luis Mining Co., of Mexico.

A. SCHWAB, consulting engineer, of Joplin, Missouri, has just completed an extensively equipped laboratory for physical and chemical testing, with a great number of flotation machines and all necessary auxiliary apparatus. The ore-testing plant is capable of handling one ton of ore, and contains practically every ore-crushing and grinding appliance and every concentrating machine of importance in use today. There are also in course of construction furnaces for all kinds of heat-treatment, and an electrolytic department.

'DUPLEX DOINGS, THE HEAVY HAULERS' MAGAZINE, for December, presents a paper on a new adaptation to trucks consisting of a power-windlass, which is of the self-contained single-drum type, with a drum 7½ in. diam. by 21 in. long, with a flange-diameter of 17 in. It is operated by a worm and worm-wheel from the transmission by a Whitney roller chain to the drum-shaft. The drum is operated by cone-friction, capable of handling a load of 10,000 lb. at a 4-in. radius. The rope-speed is 50 ft. per minute at an engine speed of 1000 r.p.m. The same issue contains articles with illustrations showing trucks adapted to house-moving, lumber-hauling, and other uses.

DON A. CARPENTER & Co is in the field with a brand-new catalogue for 1918, being issue No. 10. It is a practical list of equipment for miners, contractors, quarrymen, irrigation engineers, and for those in charge of power-plants, pump-stations, and general machine shops. The illustrations and descriptions are of the kind that enable the engineer and mechanic to definitely select what he requires, and full details for ordering are given so as to avoid mistakes. The firm is the El Paso agent for the compressors and other equipment made by the Chicago Pneumatic Tool Co., the pumps manufactured by the Goulds Mfg. Co., the Nagle boilers, shop equipment of the Canedy Otto Mfg. Co., the Champion Blower & Forge Co., and many other leading firms. The catalogue is well printed, and well-bound for service; it has useful tables and formulae for shop-practice, steam and water engineering, and for the use and control of internal combustion engines; and is also provided with an excellent index.

IN these days of freight congestion it is worth while to draw attention to the large amount of useless printed matter issued, under an official frank, from Washington. For instance, we have been receiving reports from the Department of Agriculture and from the Board of Temperance. In both cases the printed matter went into the waste-paper basket, together with much similar stuff, because it did not bear remotely upon the subjects coming within our purview, as the senders ought to have known. And what of the hundreds of tons of piffle sent broadcast over the country by members of Congress? The abuse of mailing privileges by our legislators is a national scandal, and without humor in this hour of crisis.

PUBLICATION in a Colombian engineering journal of an estimate, by Enrique U. Ramirez, of the cost of building a railroad from Bogotá, the capital city of the Republic, to the head of navigation on the river Meta, brings to mind the circumstances of our negotiations with Colombia for the Panama Canal concession. President Marroquin demanded a cash payment, insignificant in comparison with what we paid the French company for assets of no great value, and the purpose that Marroquin had in view was the construction of this very railroad. That would have afforded the great Colombian plateau an outlet to the United States and Europe with only two transfers in transit against three by way of the Magdalena, and with infinitely easier gradients and lower costs. We did Colombia a wrong at Panama that is keenly felt by our people; nevertheless the payment of 'conscience money,' as once was proposed, would only deepen the sting. It would be a practical thing, however, to finance this needed artery of commerce for Colombia and thereby help to develop the resources of that country.

WE have read portions of the January bulletin of the Institute with cynical amusement, on account of the frequent emergence, upon the surface of its pages, of several commercial controversies regarding the merits and demerits of sundry machines. The editor of the bulletin, and therefore of the transactions, has our understanding sympathy in his effort to steer a straight course among these shoals of trade rivalry. We think that the publications committee of the Institute should consider

seriously the knotty problem of distinguishing between technical disputation and trade controversy. We have animadverted more than once against the sort of paper that is a carefully prepared advertisement, for example, 'The Smith table' by Smith himself, or 'The Jones classifier', by the Hon. Jones. The volumes of the transactions of the Institute include several such trade propagandas. Now we are treated to violent disputes over the efficiency and deficiency of sundry machines. We doubt whether such disputes are advantageous to anybody. They have no value as technical evidence, because the testimony is bitterly partisan, and they are used equally to disparage the rival products. If the bulletins and the transactions are to echo the advertising pages of the trade press, then one rule should be put in force, namely, that any member of the Institute expressing an opinion on a machine should state his business connection, if any, with the manufacture of that machine or of any competing machine. Some of us may not need this information but the student of technology and the seeker after trustworthy information, whether reading the bulletins or perusing the same matter in its embalmed form in the bound volumes of the transactions, should be given this necessary warning.

ON January 14, after two months deliberation, Judge Wolverton of the U. S. District Court at Portland, Oregon, handed down his decision on the application for a temporary injunction in the case of American Smelting & Refining Company v. Bunker Hill & Sullivan Mining & Concentrating Company. In substance the Court holds that until the trial of the case upon its merits the Bunker Hill should continue to ship to the smelting company all its product containing more than 30% and less than 75% lead, but that the Bunker Hill could smelt its products outside these limitations or dispose of them as it saw fit. As a condition to the granting of the injunction, the Court first required a bond in the sum of \$20,000, which amount has since been increased to \$250,000. In the course of the opinion the Court suggests that the Bunker Hill had the right to dispose of its high and low-grade products, but that the company should not be at liberty to deviate from the custom and practice that it had followed in the years immediately prior to the controversy. We understand that the inter-

mediate product includes about half the tonnage of lead and ore produced by the Bunker Hill. The Court states that its opinion is not conclusive, but is a preliminary statement for the purpose of determining what should be done in advance of a full trial. The opinion is too long for publication, but we may mention that the Court holds that the Bunker Hill contract was assignable by the Tacoma company to the American Smelting company, and that the Bunker Hill company apparently anticipated such transfer. In referring to the contention of the Bunker Hill that the American Smelting company had formed a combination with other smelting companies to prevent the Bunker Hill from securing a market for such of its products as were not covered by the fixed terms of the contract, the Court says: "Another suggestion is that the American Smelting & Refining Company has brought about an unlawful combination with other smelting companies, so that it has a monopoly of the market for the purchase of lead ores, and for that reason that it ought not to be allowed to prevail here. While there is a surmise that such may be the case, the testimony in the record falls far short of establishing the fact."

THE War Minerals Committee has taken the position that iron, copper, lead, and zinc are not of practical importance as subjects for their consideration, because the supply of these metals is reasonably assured. They have, however, given special attention to the encouragement of domestic production of pyrite and manganese. To ensure an increase in the output of these materials it is essential to guarantee prices for a sufficient period to warrant the outlay that would be incurred in developing the available deposits. Although spot prices for domestic pyrite, for example, range from 25 to 30 cents per unit of contained sulphur, the sulphuric-acid makers will not quote such figures for future delivery. The result is to discourage the opening of new mines. Similarly, offerings of manganese lead to no transactions unless accompanied with samples and a firm proposition to deliver stated quantities ready for prompt shipment. Uncertainty as to the duration of the War is responsible for these limitations, and the only remedy is for the Government to give to possible producers assurance in some form of a return that will enable them at least to cover their outlay. The Government is furnishing the money to enlarge existing acid-plants, and it would, therefore, seem logical to foment the output of the requisite raw material. Members of the Committee suggested that the price might be stabilized for two years. That would afford some warrant for development, but it would still leave the question of disposal of the product at the Government price subject to a demand that might fail. This aspect of the matter led the Committee, with the approval of the War Industries Board, to recommend to the President that a sum of \$5,000,000 be made available by the Bureau of Mines for making definite contracts for 18 months or more for an increased supply of pyrite to be delivered to plants, designated by the Government, from

which it buys its sulphuric acid. This action is constructive and meritorious. Similar aid might be extended with propriety to producers of manganese and some other needed minerals.

Mining After the War

Under present conditions the financing of mining operations should be made with an expectation of impending changes in demand and in corresponding market-prices. We limit ourselves necessarily to the speculative mining field, without extending the argument to other branches of industry. No one will accuse us of pessimism in saying this, since we are thereby actually emphasizing the optimism of the Government in declining to fix metal prices for periods longer than four months. That means, primarily, that the Government is not convinced that hostilities will be greatly prolonged, in which event it would not continue to be a heavy purchaser, in view of the fact that its present authority for extraordinary expenditures is for the duration of the War only. No continuance of a general programme of military preparedness beyond the War has been arranged, and a great proportion of the Government contracts are on the basis of cost plus 10%. Therefore the completion of such contracts is not obligatory. Stoppage of further outlay may be ordered when desired by providing compensation for work done to the time of rescinding orders. The United States is the virtual purchasing agent for the Allies, and their credit in our market at this moment is essentially Uncle Sam's credit, since foreign settlements are effected through warrants drawn on our National Treasury against credits authorized by Congress. It must be noted that commercial foreign credits will be practically non-existent at the moment of declaring peace, and also for some time after a treaty of peace has been signed. The peace negotiations will involve so many difficult problems that of necessity the sittings of the council will be lengthy. An armistice pending these negotiations cannot permit continuance of military preparations. The market demand for raw material will, accordingly, be subjected to conditions for which no provisions have been made, and prices, at best, will be 'nominal.' Trading for a time would practically cease. We must be careful lest we be precipitated from our paradise of high prices into a *limbus fatuorum*. It is our firm belief that the Government, having taken upon itself the useful function of regulating prices, should also appoint one more committee for the purpose of drawing a well-considered plan leading to some appropriate legislation for protecting industry against the collapse that otherwise threatens to ensue as soon as the guns cease firing. Such a disaster may not be scorned because it may be only temporary. It is well enough to bolster our optimism by talk of reconstruction after the War, but it will take months to arrive at an acceptable treaty, and more months to develop an extensive programme of reconstruc-

tion and to establish the banking credits on which business may proceed. This will involve a serious check upon industry, a shortage of work for all classes of labor, discordant prices, financial timidity, and money stringency, unless wise provision to bridge that period of uncertainty be made in time. Meanwhile the larger mining operations are being based on a possible return to pre-War prices, at a reduced output, and new ventures should be directed in the light of a safe market no further ahead than the guarantee of prices by the Government.

Unto the End

We are living in days when successive crises fail to shock our imagination, just as the frequent recital of horrors makes callous our feelings. Nevertheless the moment is full of significant events. The pronouncements of the Premier of Great Britain and the President of the United States have been published so nearly together as to emphasize the essential solidarity of the two English-speaking nations and to hearten their peoples with the assurance that the two governments know what course they are steering. The War has reached that crucial stage when the actual fighting is subordinated to political considerations, because the apparent absence of a decision on the battlefield is joined to the hardships that winter brings upon the warring peoples. The men at the front—our gallant defenders in the trenches—do not doubt the issue, we do not doubt them, but they are asking if the people at home will see it through, if they will hold firmly to the end. Signs multiply that the nations of Europe are weary of fighting, they count their losses and ask anxiously 'How long'? Lack of food and fuel begins to sap the ardor of the onslaught. This is the moment when the quitter falters and the stickler stays; in conventional language the morale of some of the belligerents appears to be weakening. Shall frightfulness triumph over a blood-soaked world; shall the outlaw be conciliated with fresh scraps of paper? France lifts a mournful face in which firm resolve gleams undimmed; Britain smiles with the set teeth of a bulldog; America raises her hand and shouts, 'We come!' If there is to be any quitting, it will not be among these. Our leaders have stated our aims—enough of that—it is hits that count henceforth. Peace talk, with its poison gas of bolshevik anarchy, must await the only conclusion that will restore civilization. Germany has seceded from civilization. The world cannot remain half-slave and half-free. Either this canker of military ruthlessness must be cut out or we relapse to a scientific barbarism. Are we to be cogs in an infernal machine or citizens each in his own democracy, free to live and let live? It is one or the other. The Prussian has not changed the spirit of his paranoiac dream, the Pan-German still hopes to make good his will to conquer. A few days ago General von Lieb in a speech before the German Conservative Congress said: "We must recognize only one principle, namely, that might is right, and must know neither senti-

ment, nor consideration of humanity, nor compassion. We must have Belgium and northern France. The curse of God is upon the French. France must be bled white. We must have a strong peace." There speaks the voice of the beast with the brains of an engineer, undaunted by the world's reprobation, unfeeling for the butchery he has provoked. In every great war there comes a moment when the issue seems either doubtful or unsettled; that is the moment when moral courage gives a new edge to physical bravery. Such a time came after three years of the Civil War; such a time came in the Napoleonic struggle after the battle of Friedland, when the Allies signed the treaty of Tilsit and legalized Napoleon's conquests, thereby committing Europe to eight more years of warfare. At Friedland the Russian army was so badly beaten that the Czar and the King of Prussia capitulated. But England continued to fight Napoleon in Spain and on the sea, and by her tenacity of purpose eventually rallied the Allies to final victory at Waterloo. France, England, the United States, and their allies, mean to fight to a sure decision, although it is likely to be brought about not by any single battle but by a steady hammering of the Enemy. We are fighting for peace, for a peace that shall endure, not a patched-up truce enabling the Enemy to re-organize himself for another spring at the throat of civilization. A treaty with an outlaw is a scrap of paper. Our aim is to create a league of nations committed to the preservation of international order. Shall we ever have a league more effective than the one now existing among the Allies? If this league cannot bring the breaker of the peace to his knees then no imaginable combination in the future can do so. Now is the chance to prove to the world that predatory militarism is a punishable crime, that it is incompatible with social progress, and that a majority of civilized nations is ready to check it with all the resources of outraged humanity.

The Fuel Order

On January 17 Mr. H. A. Garfield, the head of the U. S. Fuel Administration, issued an order for regulating the supply of coal throughout the country, for the purpose of expediting the shipment of supplies of war from our ports to our own army and to the armies of the Allies in Europe. In order to accomplish this purpose an executive mandate was issued, forbidding the burning of fuel by manufacturers east of the Mississippi river, except those engaged in a few classes of work connected with the War, on January 18 and for four succeeding days; also on every Monday from January 28 to March 25. This order evoked many protests and much verbal confusion. Four pronouncements of opinion should be noted. Mr. Samuel Gompers, speaking for the American Federation of Labor, said that the workers of the Nation will be the greatest sufferers from the fuel restriction order, but "they will maintain their loyal stand, despite the suffering and sacrifices which they may be called

upon to bear." The War Service Executive Committee of the Chamber of Commerce of the United States issued a statement criticizing the order, but announcing that, since it had been issued, "it is clearly the duty of business men to do all in their power to carry out its spirit and purpose." Mr. Elbert H. Gary declared on behalf of the United States Steel Corporation: "We probably shall not pay the wages of our men when they are not actually employed. To do so would be contrary to the custom of the trade, and would establish a precedent which eventually would be unfair to the employer as well as to the employee." At the close of an explanation issued by Mr. Garfield himself, he said: "This is War! Whatever the cost, we must pay, so that, in the face of the enemy, there can never be the reproach that we held back from doing our full share. Those ships laden with our supplies of food for man, and food for guns, must have coal and put to sea." These four statements will, we believe, reflect the opinion of the intelligent portion of the public. The existing shortage of fuel does not represent inability to move the quantity normally consumed. On the contrary, more coal has been delivered by the railroads during the year 1917 than ever before in the history of the country. The Geological Survey estimates that the output of the mines was approximately 50,000,000 tons greater than in 1916, and in that year the record of previous production was broken. The National City Bank of New York is responsible for the statement that practically no stocks of coal exist outside consumers' hands. The evidence clearly indicates that two factors have produced the unusual situation that the Government undertook to meet by a suspension of manufacturing. These factors are, first, increased fuel consumption resulting from the intensive production of supplies for War, in addition to those needed for domestic use, and, second, the inadequacy of transportation facilities to cope with the vastly augmented tonnage of coal necessitated under these unusual conditions. The difficulty has been aggravated by an exceptionally severe winter, involving a suddenly enlarged demand for household purposes, at a moment when the railroads were further crippled by snow-blockades and the many impediments to operation that follow from excessively low temperatures. Mr. William M. Calder, in the Senate, called attention to the fact that the Fuel Administration had interdicted the buying of coal during the summer season, declaring at that time that the shortage was psychological rather than real, and that the accumulation of such supplies for household or other requirements would be deemed hoarding. It will be remembered that the failure of the railroads to handle successfully the growing volume of freight was the subject of a special report by the Federal Trade Commission presented to Congress as far back as June of last year, coupled with a definite recommendation for Government control of the transportation systems. The inevitable conclusion from all the facts is that there has not been proper co-ordination of the governmental departments, bureaus, and committees

that are responsible for the practical work of directing the activities of the country. In consequence of this lack of co-ordination the welfare of the people and our preparation for the business of War have suffered. This criticism has been repeated frequently by many sincere and earnest patriots on the floor of Congress and in the press, but it has gone unheeded. In the storm of Congressional debate provoked by Mr. Garfield's order a number of Senators accorded the President the warmest praise for untiring devotion to his overwhelming duties, but they reminded him that he was attempting the impossible in personally struggling with such multitudinous details as the present administrative organization forced upon him. It is manifestly beyond the power of a single individual to harmonize the efforts of the numerous branches into which the executive authority of the Government has been subdivided to meet the exigencies of the hour. This had been so fully realized by Congress that bills were drafted by the Military Committee of the Senate just before the emergency fuel order was issued, providing for the appointment of a director of war industries, and for a non-partisan war cabinet of three members to stand between the President and the usual cabinet, the duty of which extraordinary council shall be specifically to co-ordinate the work now being performed by the several departments and special committees. It is fortunate that these bills were drawn before the flood of protest evoked by Mr. Garfield's action. Thus no sting of criticism is involved in them, and the President can accept the measures, if passed, in the spirit of constructive aid that prompted those who framed them. The country will also feel an added confidence in the conduct of the nation's affairs. No one can ignore the fact that popular confidence was rudely shaken by the drastic action that was taken to remedy the fuel shortage. It was a difficulty that apparently could have been avoided by greater foresight. Better organization will be needed now to assure a cordial settlement of the difficulties likely to arise from the temporary stoppage of so many industries. Heavy losses are sure to result, and it is plain that the burden will not fall equally upon those affected. Manufacturers operating on the basis of cost plus 10% can evidently pay their workmen during the period of idleness, charging the amount in their costs, while those operating independently would suffer without remedy. Already we see that prominent business men reject the plea to continue the payment of wages as a patriotic duty. No provision for compensation has been made by the Government, and if money is withheld from the laborers the consequent distress will necessitate instant relief, together with ample assurance against the recurrence of such painful incidents. That the action taken by Mr. Garfield was imperative under the existing circumstances will be accepted by the people with good grace, but those circumstances should not have been allowed to arise, and it is the duty of those in authority to grapple more firmly with the problems arising from the extraordinary conditions of war.

DISCUSSION

The Domestic Production of Chrome

The Editor:

Sir—The war meeting of the New York Section of the American Institute of Mining Engineers (sitting in joint session with the American Electro-Chemical Society in conjunction with the third National Exposition of Chemical Industries) was held to discuss the supply of raw materials for the manufacture of ferro-alloys. Chrome received the principal consideration.

The domestic production being only 47,035 tons as against an importation in 1916 of 115,945 tons, the question was raised as to how much could the United States supply from its own mines? Attention was also called to the apparent exhaustion of the known deposits.

No doubt there is plenty of chrome available in New Caledonia and Rhodesia, but to obtain this ore it becomes necessary for the United States to send ships that are at present needed to transport food to the Allies. If necessary we can, of course, do this, but is it an act of patriotism for our industries to compel our Government to import this ore without making a greater effort to develop our own deposits? I believe there is little question in the minds of the Western miners that if it were necessary the United States, with Alaska, could produce all the chrome ore demanded for the manufacture of munitions. There is, however, good reason for doubt, because, if the present policy on the part of our buyers is maintained, there will be considerably less offered in the future than is at present available. I refer to the secretive and non-cooperative policy maintained by the consumers of chrome ore in their effort to keep down the price of this raw material. I believe it is a mistaken and short-sighted policy on the part of the consumers not to offer more encouragement to domestic production, especially at a time when ocean-going space is in such demand.

It has been said that a rise in the price of this ore would not materially increase the production. I submit figures herewith showing the enormous increase in the production of this ore in the United States within the last five years due to the slight increase in price.

PRODUCTION OF CHROME ORE

Year	Tons	Price per ton
1913	255	\$11.19
1914	591	14.75
1915	3,281	14.85
1916	47,035	35.00
1917	48,000	40.00

In order for us to consider thoroughly the question of how much the United States will produce it is necessary

to investigate both the physical features surrounding the occurrence of chrome ore, and also the economic question under which these ores have to be marketed.

Chrome is widely disseminated throughout the Pacific Coast states; it is found in more than one-third of the counties of California, which alone produced more than 40,000 tons in 1916, or more than one-third of the total imports into the United States for that year. Chromite occurs in workable quantities in Oregon, Washington, and Alaska. These regions have been but little prospected for chrome and they will not be prospected until such time as the practical miner learns of the market value of such ore.

The consumers may send out all the expert mining men they wish to work these deposits but they are not going to develop a source of supply for a mineral hitherto considered worthless until they educate the practical miner, the prospector, and the farmer as to the value of it. They are not interested in chromite and unless an incentive is given they are not going to become interested; for that reason I am strongly of the impression that it would do much to stimulate the discovery and the opening of new deposits if more assistance and co-operation were given to the small producer, especially regarding publicity as to the true market-value of the various grades of chromite instead of making it as difficult as possible for him to ascertain the real value of his ore. He not only should know the value of a particular ore, but he should be able to ascertain the relative value of the different grades of ore and concentrate. There are many deposits of this ore slightly below the grade required by the consumer that, by simply crushing and concentrating, would furnish a high-grade chemical ore.

Chromite orebodies as a rule occur in relatively small deposits. J. S. Diller of the U. S. Geological Survey says the largest orebody yet mined on the Pacific Coast contained about 15,000 tons. Most chrome deposits are formed as a crystallization or segregation, during the process of cooling, of the chromite contained in molten igneous masses, and for that reason the mining of these orebodies is uncertain. There are many places where the mining of these pockety deposits, although not sufficiently attractive to pay for the operation and overhead expenses of a company, might be undertaken by the individual miner.

Although the buyers have succeeded in keeping the price of the raw chrome down within narrow limits, such a policy of secrecy is not to the welfare of the industry, and it certainly does not develop mines for production of

raw materials. Rather than the present policy of mystery, the producers should be made acquainted not only with the technical part of its production but also with the uses to which it is put. Although most of the writers upon the subject of chromite refer to its application in the refractory-brick business they present no figures showing the consumption of chrome in the steel industries, and the producer is left in the dark as to the use made of his ore and regarding the future demand.

As a rule, all that the miner or prospector wants is a sufficient return to permit him to do more mining, and if, perchance, he does make a profit in the mining of a few hundred tons of ore, he is more than likely to re-invest his funds in the search for additional deposits. A more liberal and frank policy practised by the industrial companies purchasing the raw ore would not only stimulate development, with the possibility of additional orebodies being found in the districts at present becoming depleted, but it would be cause for the investigation of the chrome fields at present unexplored in Washington, Oregon, and Alaska.

San Francisco, December 31, 1917.

Excess-Profit Tax for Mines

The Editor:

Sir—The proposal of Albert Burch, quoted in your editorial of January 12, as modified in the same editorial, comes near being a satisfactory solution without, I think, quite reaching it.

The problem is to secure for the State a large, but equitably distributed, share of the profits arising from increment in value of mining products, due to the War, without discouraging production from any source. It is in this direction that I think Mr. Burch's proposal fails. It is of the greatest importance to increase production, both because the metals are required for the effective prosecution of the War, and also because production tends to keep down prices. We need the production even if it is unprofitable or inadequately profitable; and the high-cost mine may furnish just that extra margin of product which may save us from runaway markets or actual shortage.

To secure both ends, the increment of price which should regulate the rate of taxation should be only that in excess of 50% above the average pre-war price (50% representing the estimated increase in costs, due to the War). The tax should, however, be assessed only on the profit actually made, not on the excess value of the products marketed. This will, of course, result in stimulating production from some mines which will have to close down after the War; but it is exactly this production that we need now. If we do not obtain it, sooner or later we may either risk failure on account of scarcity of essential metals, or be compelled to produce them at the expense of the State.

I would therefore re-state Mr. Burch's formula as follows:

In the case of mines, oil-wells, and gas-wells, the increase in the average price received at place of sale for each unit of product (that is, each ounce, pound, ton, barrel, or cubic foot, as the case may be) for the taxable year, over the average price at which the same unit was or could have been sold at the same place during the pre-war period, shall be ascertained; and the percentage of such increase beyond 50% shall be used as the basis on which the excess-profit tax shall be computed. The said tax shall consist of not less than 20% and not more than 80% of the entire profit for the taxable year. Whenever the percentage of increase of price of product as aforesaid shall exceed 50% the tax shall be 20% of the profit for the year, and whenever the percentage of increase of price of product shall be 200% the tax shall be 80% of the profit for the year; intermediate rates of increase of price of product fixing the war excess-profit tax at proportionately intermediate percentage of the annual profit.

This proposal would contemplate allowance for depletion, etc., remaining on the same footing as under the present law.

GEORGE E. COLLINS.

Denver, January 16.

Food Saving

The Editor:

Sir—Since last July we have been very busy re-building, after our fire, and making new trials, as we have changed the location of our buildings. I had no chance to read the PRESS until a month ago, when I picked up what magazines I had left from the fire and saw the Hoover 'ad,' and here it is signed and returned to you, as requested. I am *chef de cuisine* and food economist, so it will be my good fortune to help the cause a little. Wheat flour has gone up 100% since the beginning of the War, yet we pay less by \$2 to \$3 per barrel in Elk City than we paid for it 10 years ago; the parcels-post reduced our price here. From necessity of high prices, and the little work to be had, I evolved a wheat bread that is from 25 to 40% camouflage, a bread that tastes as fine as any Vienna roll ever did, and, according to Mr. Hoover's precepts, I am now saving from 25 to 40% wheat on every loaf I bake, although I have not a wheatless meal a week. Stale bread, pieces or whole bread, will make so many excellent dishes that there is no reason whatever for a single piece of bread, no matter how dry, to be wasted. The savings to be made by Mr. Hoover's plan will be enormous, unbelievably so; and the health of the nation will increase 100%. Let us all be Hooverized, voluntarily or by force.

FREDERICK GRIEL.

Elk City, Idaho, January 4.

NITRATE OF SODA will be supplied for fertilizers by the Government this season at \$75.50 per ton. The current market rate has dropped to \$88 for 95% grades on the spot. It is said that larger amounts of Chilean nitrate are now afloat bound for this country.

CUT THROUGH COPPER MOUNTAIN. THE GAP REPRESENTS ORE REMOVED

Ajo Copper Mine—I

By COURTENAY DE KALB

At the town of Ajo, in the western end of Pima county, Arizona, is a copper mine now recognized among the great ones of the world. It is being worked by steam-shovels, and the ore is leached with sulphuric acid, after being crushed to $\frac{1}{4}$ inch. The monthly shipments of copper exceed three million pounds. The property is not yet completely developed, but 61,000,000 tons of ore averaging 1.51% copper has been definitely proved. This notable addition to the nation's available supply of that metal must be credited primarily to the courageous initiative and unflinching confidence of John C. Greenway. He was not alone in his conviction that Ajo would develop into a premier mine, for he was sustained by the mature judgment of L. D. Ricketts; but the least weakening of his own faith in the enterprise during the earlier period of development might have led to its abandonment. The degree of courage required may be inferred from the fact that Ajo labored under the burden of a history of successive condemnations by men of large experience in 'porphyry' mines. These were men who knew the characteristics of disseminated deposits; who understood the criteria of secondary enrichment; and they had even made tests by rather extensive drilling. In the end they withdrew, and nothing is more difficult than to resuscitate a mining district that has been investigated by competent engineers, supported by abundant capital, and then deserted as worthless. Moreover, Capt. Greenway, now major of engineers in France, whose military title was won as a Rough Rider in the Cuban campaign, faced a technical staff that was distinctly cold toward the Ajo mines. The first reports were not flatly condemnatory, but an adverse argument was involved in the faint praise given. He, however, was ambitious to sponsor a great disseminated copper property, and the features that had drawn his predecessors to look curiously at Ajo encouraged him to take the rather doubtful chances of

success admitted by his advisers. In the end it proved that the earlier drilling had narrowly missed the important orebody, and that the expected enrichment did not exist, for the Ajo deposit has not been secondarily enriched. It consists of an upper zone of copper carbonate and a lower zone containing primary chalcopryite and bornite. The difference in the copper content between the two is only 0.04%, with the higher proportion in favor of the carbonate. Acid leaching had been prevented by abundant calcite formed during a period of alteration that preceded the introduction of the copper, and sericite is so nearly absent that it can be detected only to a small extent by examination with the petrographic microscope. Thus it is evident that the Ajo deposit presents no analogies to the secondarily enriched 'porphyries' from which previous experience in disseminated copper ores had been gained. It was distinctly *sui generis*.

Part of the early history of Ajo has been given by Ira B. Joralemon.* He notes that, next to Santa Rita, New Mexico, it is the oldest centre of copper production in the South-West. Mr. Joralemon credits the first operation to the early 'sixties, but in reality the work began in 1855, and in the following year a shipment of high-grade ore was made to San Francisco by the Arizona Mining & Trading Co. This was a sort of company of gentlemen adventurers, organized in the spirit of true pioneering, with no more substantial objective than infinite hope in the possibilities of an unexplored country. The organizers were Major B. Allen, J. D. Wilson, William Blanding, A. S. Wright, and others resident at Los Angeles. An expedition was outfitted in that city in 1854, under the charge of E. E. Dunbar. It consisted of 20 men, among whom were F. Ronstadt, P. Brady, G. Kibbers,

*'The Ajo Copper Mining District,' Trans. A. I. M. E., Vol. XLIX, pp. 593-609.

George Williams, Joe Yancy, Charles Hayward, and a Dr. Webster. They went first to Yuma, where the expedition was divided, one party, caught by the lure of a lost mine, plunging into the wilderness in quest of the ever elusive Planchas de Plata vein, while the other, following the trail to Tinaja Alta, heard of the Ajo copper mines 90 miles east-southeast from Yuma. They found these mines to be real, and soon established themselves in possession; but mining in Arizona in 1854 required familiarity with arms as well as with the pick. The new international line, as described in the treaty for the Gadsden Purchase, was still undetermined by survey, so the Mexican authorities undertook to wrest the mines away from the Americans, but they were defeated by effective resistance organized by Hayward. The first ores shipped came from excessively rich narrow deposits of cuprite and native copper, found near the contact between the intrusive monzonite and the older rhyolite, near the western end of the present workings of the New Cornelia Copper Co. Subsequently, rich narrow veins of chalcopyrite and chalcocite in the rhyolite were the source of ore that kept the district feebly and intermittently active for half a century. For a time the ore was hauled in ox-carts 400 miles across the desert to San Diego, and later it was taken to Yuma, to be floated down the Colorado river in barges to the head of the Gulf of California. From this point it was shipped to Swansea. The second period began about 1900, when a series of fiascos followed the attempts made by numerous companies to exploit the small rich deposits in the outlying region around the great mass of low-grade ore. Stamp-mills were erected, and patent processes for reducing and refining the copper were tried, among these being efforts to leach the ores with hydrofluoric acid. In 1909 a fresh venture was made, and this time by responsible people. The original New Cornelia Copper Co., one of the moribund concerns of the stock-promoting epoch, was taken under option by the General Development Co., and the holdings of the Rendall Ore Reduction Co. also were tested by a group of capitalists advised by Seely W. Mudd. After a brief campaign of drilling both options were abandoned, but in 1911 Capt. Greenway took an option on the New Cornelia property for the Calumet & Arizona Mining Co. Instead of testing the low-lying areas around Copper mountain he directed his attention to the rugged group of hills that has proved to be the centre of mineralization. Mr. Joralemon describes these hills as being "highly stained outcrops." Whatever may have been the character of the central zone through which since then the steam-shovels have made a deep wide open-cut, the remainder of the area of 55 acres is surprisingly destitute of green coloration, except where broken in the course of exploratory work. The outcrop, however, is clearly marked; it consists of a number of low, barren, rocky hills surrounded by high peaks and ridges of gray granite and rhyolite. The prevailing tint of the encircling mountains might be described as pale grayish lavender. The copper terrain is distinguished by a warm russet hue, indicating an excess of iron. The form of the mineralized

hills is rounded, but the bare rocks have a short angular fracture, and are encrusted with the desert glaze. Here and there a bit of copper carbonate appears, and a dark-green stain is not uncommon on sheltered faces of the rougher and larger blocks. A surprise comes, however, on breaking the rock with a hammer. No matter where one strikes it the stain of copper carbonate is revealed. It reaches up to the very crust of brown glaze that had obscured it; through every seam opened by the hammer, the green film penetrates. On breaking a few inches deeper the feldspars of the monzonite display a pale greenish tinge, and this minute coloration proves to be leachable, even without reducing the rock to a fine state of subdivision. Looking at the walls in the open-cut, as they are blasted down to feed the steam-shovels at their feet, the appearance is not that of ore but of rock merely permeated with greenish tints; and one recalls the common joke about a mountain stained with a copper cent. It seems, in fact, like mining a stain and making it pay. From this it must not be concluded that the ore is wanting in signs of richness. As finally broken ready for loading by the steam-shovel, the color of a pile of ore is dirty greenish gray, but on large blocks the seam-deposits are often thick and exceedingly brilliant in color. Turquoise-blue to verdigris-green are the prevailing shades. In places the incrustations are no more than a film, but more generally they constitute a scale of copper mineral that can be stripped with a knife, and many seams are found as much as an inch thick. This is in accord with the habit of the deposit. In monzonites that have not undergone profound alteration, such as sericitization or chloritization, the jointing developed in the final set of the rock is generally irregular; mineralization by sulphides follows the joint-planes, and, to a less extent, depending upon the degree of compression of the mineralizing gases, the sulphides invade the body of the rock, replacing primarily the ferro-magnesian minerals. This order is observed frequently, and it is seen in the Ajo deposit. The most striking feature to the eye, on examining the sulphide ore from the lower unoxidized zone, is the abundant deposition of the sulphides, both chalcopyrite and bornite, on seams and joint-planes. They form crusts and patches as well as crystalline flakes scattered quite regularly over the surface. Narrow veinlets of bornite and chalcopyrite suggest replacement of seams of segregated basic minerals, these being tightly coherent to the body of the rock, showing quartz often developed as prisms protruding into vugs. Cuprite occurs in the oxidized zone in the same manner; in fact, most of the recognizable cuprite is in veinlets cemented into the monzonite; some of the masses of cuprite would weigh a pound or more. Cuprite is also seen in such veinlets in the sulphide zone, where it is well crystallized, and of a dark color, but easily recognizable by the splinters that flash ruby-red by transmitted light. The copper sulphide is disseminated also, and appears to exist mainly as bornite. In the process of mineralization the volume removed has generally been in excess of that deposited, leaving the rock with a rough and minutely pitted sur-

Calcite (C) replacing quartz (Q) and feldspars; sulphides (S) replacing all minerals. Mag. $\times 83$.

face; this is a feature observed in other examples of mineralized monzonite. Chlorite is general as a secondary mineral, having resulted from the alteration of biotite chiefly. Some siderite is also found; it is secondary, but is not always conclusively a product of the period of oxidation during which the copper was converted to carbonate. Much magnetite is present, and this, as well as specularite, is found with the ore, the specularite appearing most commonly on seams and joint-planes. Apatite is also abundant, but not to be detected in examination of specimens with a hand-lens. The phosphorus appears regularly as a constituent of the solutions in circulation through the leaching-plant, as shown by analyses of weekly composite samples, which contain from 0.162 to 0.184% of phosphoric acid. At times the solution holds 0.3% P_2O_5 . The chlorine in the solutions is from 0.01 to 0.008%, and this, plus the chlorine deposited in the cathode copper, is fully accounted for by the chlorine in the water used for leaching, which carries 0.015%. The ore shows no chlorine whatever, hence the phosphorus is assumed to be present in the form of the fluo-apatite. The scarcity of sericite has already been noted, though it appears scattered rather abundantly through the mineralized rhyolite at the south-west end of the monzonite orebody.

The structural features of the deposit have been lucidly set forth by Mr. Joralemon,[†] who interprets the known relations of the monzonite as indicating a laccolith, over which the rhyolite is domed. Drill-testing, still in progress on the south-west side of the outcrop, beyond the point where the rhyolite is first seen shouldering over the monzonite, has penetrated to a depth of 1100 ft. and has not yet reached the monzonite. The drill-core, however, shows a great deal of native copper, so that it is apparently approaching near the zone of mineralization. This indicates, also, that the dip of the contact between the two rocks is becoming steeper. Whatever additional light this may throw upon the relation of the monzonite to the overlying rocks, it does indicate at least an approach toward its southern limit. Mr. Joralemon states that the monzonite laccolith, or 'batholith', which lifted the earlier rhyolite beds, is 10 miles long and of irregular width, varying from 1 to 4 miles, the direction of its major axis being N. 20° W. Toward the north the monzonite constitutes a series of high precipitous ridges, and in this portion of the exposure the facies is quite generally that of a coarse grano-diorite, with biotite prominently developed. Phases of more distinctly dioritic segregations are common, and Mr. Joralemon calls special attention to the fact that "diorite or diabase dikes cut both monzonite and rhyolite, but apparently have had no important effect on structure or mineralization." They are apparently complementary to the monzonite, thus accounting for the absence of secondary effects upon the parent magma. The dikes, however, have been pyritized, and their outcrops are very ruddy; the later fracturing through the monzonite, to which is ascribed

the opening of avenues for the invasion of the mineralizing agents, is also seen following the dikes, and these narrow brecciated and faulted zones, even at a considerable distance from the orebody, display epidotization, with accompanying calcite and secondary silica, both in seams and throughout the body of the adjacent rock, while sulphides of copper and larger amounts of pyrite are in evidence. Many of these subsidiary veins throughout the otherwise 'dry' monzonite area have been explored by prospect-shafts. The monzonite is generally gray and hard, in which case considerable hornblende is usually present, but in other places it weathers to coarse, rough, granular particles, and is then highly stained with iron oxide. This is particularly noticeable on the north side of Copper mountain. A short distance north-north-west from the edge of the orebody the monzonite is profoundly saussuritized, and it may be said that alteration to saussurite and epidote is characteristic over a large part of the outlying area; this is true, at least, for a distance of a mile northward from Copper mountain, and it affects the diabase dikes as well as the granodiorite. One of the surprising features of the orebody on its northern side, where a geological section can be readily traced by exposures, with the exception of about 200 ft. where obscured by 'wash', is the suddenness of the transition from mineralized to unmineralized ground. The limiting zone seems to be further defined by a more dioritic phase of the monzonite. The accompanying idealized sections, taken from Mr. Joralemon's paper, previously cited, show the chief features of the geology. The mushroom shape of the orebody is a unique characteristic, and the core of the deposit is the locus of a network of fractures, some of which reveal displacement, with slickensided walls. The nearly horizontal division between the carbonate and the sulphide ores conforms to the water-table, and the change from the oxidized ground at this level is abrupt.

Further information concerning the mineralogic character of the Ajo ore is available from a study of thin sections and polished surfaces, made by Z. K. Meleon at Stanford University under the direction of C. F. Tolman Jr. The minerals present in the ore from the sulphide zone, in the order of relative abundance, as determined by Mr. Meleon, are quartz, orthoclase, biotite, plagioclase, and magnetite. The quartz and orthoclase are prominently developed as phenocrysts, and the rock approaches more nearly the type of a granite-porphyr. Alteration has affected all the minerals, and even the quartz has not been immune. The orthoclase shows corrosion around the edges, while the body of the mass is converted into a gray substance consisting in an aggregate of minute specks that are probably kaolin. Biotite is universally altered, especially on the borders, to chlorite, magnetite, and leucoxene. The biotite was evidently unusually rich in titanium. The plagioclase was so readily attacked that only fragments remain; this mineral has chiefly suffered from calcitization, from which it may be inferred that it supplied much of the lime for the formation of the calcite. Sericite is a minor product of alteration, in places being

[†]Loc. cit. supra.

developed as well-shaped lath-like crystals, and again as minute aggregates. It replaces any of the rock-forming minerals, and is also found replacing both bornite and chalcopyrite. Secondary quartz, like the calcite, follows veinlets, and consists of small crystals occupying interstitial spaces. Bornite and chalcopyrite replace any of the other minerals, including the calcite and the secondary quartz. Preferably the sulphides replace the biotite, and even the smallest crystals of the mica show some bornite or chalcopyrite. The evidence points to the simultaneous introduction of the copper minerals. Fingers of bornite are found entering or enclosing chalcopyrite, and the reverse is equally common. Covellite is scarce, but it is seen in the unoxidized specimens closely associated with both bornite and chalcopyrite, taking the form of clusters of needles penetrating the other sulphides. It represents the only enrichment that has taken place. Chlorite is present as a persistent product of alteration from biotite, and is seen also as irregular masses.

The oxidized ores have been so deeply altered that their original constituents are no longer recognizable. The quartz is distinguishable, and to a less extent the biotite also. Limonite has resulted from the oxidation of the magnetite. The copper exists mainly in the form of malachite; next in abundance is chrysocolla; while cuprite is erratically developed, remaining to a large extent as a core in veinlets of malachite. An interesting fact revealed by the long campaign of leaching experiments is that no water-soluble copper has ever been found.

(To be continued)

Copper Production for 1917

The production of copper in 1917 was slightly less than in 1916, according to preliminary figures and estimates collected by B. S. Butler, of the U. S. Geological Survey, from all plants that make blister copper from domestic ores or that produce refined copper. At an average price of about 27 cents per pound the output for 1917 has a value of \$510,000,000, as against values of \$475,000,000 for 1916 and \$190,000,000 for 1913.

The figures showing the smelter production from domestic ores represent the actual output of most of the companies for 11 months and the estimated output for December. The production of blister and Lake copper from domestic ores was 1,890,000,000 lb. in 1917, against 1,928,000,000 lb. in 1916 and 1,224,000,000 lb. in 1913.

The output of refined copper (electrolytic, Lake, casting, and pig) from primary sources, domestic and foreign, for 1917, is estimated at 2,362,000,000 lb., compared with 2,259,000,000 lb. for 1916 and 1,615,000,000 lb. for 1913.

According to the Bureau of Foreign and Domestic Commerce, the imports of unmanufactured copper of all forms for the first 10 months of 1917 amounted to 460,780,000 lb., as against 397,594,000 lb. for the first 10 months of 1916. The imports for the year 1916 were 462,335,000 lb. The exports of pigs, ingots, bars, plates,

sheets, rods, wire, and other copper products for the first 10 months of 1917 amounted to 953,876,000 lb.; the exports for the first 10 months of 1916 were 655,473,000 lb. Similar exports for the year 1916 were 784,006,000 pounds.

At the beginning of 1917 about 128,000,000 lb. of refined copper was in stock in the United States. By adding this quantity to the refinery output of the year it will be seen that the total available supply of refined copper, exclusive of secondary copper, was about 2,490,000,000 lb. By subtracting from this quantity the exports for the first 10 months and the estimated exports for the last 2 months, and assuming no change in stocks, it will be seen that the supply available for domestic consumption in 1917 was materially less than the 1,430,000,000 lb. available in 1916.

The average monthly quoted prices of copper in 1916 and 1917 were almost exactly the same, 27.2 cents per pound. The average quoted price in 1916 was about 2.5c. more than the actual average price received. The actual price received in 1917 was probably nearer the average quoted price.

Arizona produced 687,800,000 lb., a slight decrease from the production in 1916, which was 694,800,000 pounds.

Montana produced 278,000,000 lb., as against 352,000,000 lb. in 1916.

Michigan produced 275,000,000 lb., an increase over the 269,794,000 lb. produced in 1916.

Utah produced 245,000,000 lb., as compared with 232,000,000 lb. in 1916.

Nevada produced 110,000,000 lb., an increase over the 100,800,000 lb. produced in 1916.

Alaska, with a production of about 87,500,000 lb., showed a large decrease from the previous year.

New Mexico increased its production to 104,500,000 lb. from 79,800,000 lb. in 1916.

The production of California was considerably above the 43,400,000 lb. produced in 1916.

The production in Tennessee did not differ greatly from the production in 1916, which was 14,500,000 pounds.

RESPONDING to the call to economize fuel a meeting of representative men was held at Albany, N. Y., and it was recommended that the use of stump-wood be encouraged. It was shown that the demand for such fuel had grown measurably in recent months, and that \$3 worth of dynamite would break up the equivalent of eight cords of wood. Utilizing stumps helps to pay the cost of clearing 'cut-over' land, which is needed as virgin soil to increase our crops during the War.

BLEACHING-POWDER is normally produced to the extent of 500,000 tons per year. The electrolysis of common salt has been largely developed to increase the supply of this material in the United States during the War. The result is that this country will hereafter be self-supporting as to this commodity.

Explosives

By F. H. MASON

Probably never before in history has such a vast quantity of explosives been detonated at one time as that which exploded accidentally—at least, we hope so—in the ill-fated 'Mont Blanc,' in Halifax harbor, razing the north end of the city, and leaving the work of destruction to be completed by fire. The horror of the catastrophe, people in San Francisco are perhaps better able to realize than the citizens of most other cities, for many of them have been through a somewhat similar experience. A few minutes after the 'Mont Blanc' and the 'Imo' collided 400 tons of trinitro-toluene and picric acid exploded. The terrific force of the explosion laid half of a city of 50,000 inhabitants in ruins, broke windows 60 miles away, and caused people on board a ship 40 miles at sea to think they had struck a mine. Much has been written since the 'accident' about the superior explosive qualities of trinitro-toluene, whereas, as a matter of fact, its explosive force is less than that of picric acid or trinitro-cellulose or some other nitro-explosives, but it has been selected in preference to them on account of its more stable qualities. When toluene is treated with nitric acid three nitro-derivatives can be produced: successive hydrogen atoms being replaced by nitrous acid, thus:

Trinitro-toluene is a yellow crystalline powder, melting at 79°C. When detonated with a fulminative cap it explodes with great violence and gives off dense black fume, whence the name 'black Maria' and 'coal box' that the soldiers have given to explosive shells charged with it. The products of combustion are, besides carbonic acid and nitrogen, carbon monoxide, free carbon, and hydrogen. Trinitro-toluene is often mixed with an oxidizing agent, generally ammonium nitrate, and sometimes aluminum dust, and small quantities of carbon are added. Trinitro-glycerine $C_3H_5(NO_2)_3$, on the other hand, is a self-contained explosive, that is, it contains more than enough oxygen for the complete combustion of its other ingredients; the products of the explosion are carbonic acid, nitrogen, and water, together with 4% of free oxygen.

When phenol, or carbolie acid, is mixed with an equal weight of sulphuric acid and the mixture is gradually added to three times its weight of nitric acid, trinitro-phenol or picric acid is produced. It is a lemon-yellow crystalline substance melting at 122.5°C. It was employed extensively under the names of lyddite and melinite for charging shells used in the South African war, but was found to be untrustworthy, sometimes exploding prematurely, and at other times not at all. Cordite is one of the most trustworthy explosives. It is made by mixing trinitro-glycerine and trinitro-cellulose

together and dissolving them in acetone or some other common solvent. Five per cent of vaseline is added to increase the stability, and to lubricate the gun. When gelatinization is complete the substance is pressed through a die of the desired size, and the resulting 'cord' is wound on a reel and allowed to dry until the last trace of acetone has evaporated. In the case of thick cords, the drying operation sometimes takes as long as two months. Such accuracy is obtained in the manufacture of cordite that the plus or minus velocity is only 40 ft. in the prescribed velocity for rifles of 2380 ft. per second, according to the British regulations. Probably the most powerful explosive known is tetranitro-aniline and tetranitro-methylaniline. The latter, under the less formidable name of 'tetryl,' is sometimes used as a substitute for fulminate of mercury in detonators. Recently, too, lead hydrazoate or triazide, PbN_6 , has been employed for the same purpose.

Copper and Aluminum

The following data, prepared for the British Aluminum Co., are not generally accessible and may be useful to those having electrical and other problems to solve.

Property	Copper	Aluminum
Position in electro-chemical series.....	24	10
Melting point, deg. C.....	1100	655
Melting point, deg. F.....	2010	1210
Specific heat (water = 1).....	0.094	0.212
Thermal conductivity (silver = 100).....	73.6	31.3
Electric conductivity (silver = 100).....	59.5	27.5
Co-efficient of linear expansion per deg. C	0.0000167	0.0000234
Specific gravity, rolled or drawn.....	8.89	2.71
Tensile strength in lb. per sq. in.....	560,000-63,000	26,000-93,000
Tensile strength in kg. per sq. mm.....	28-42	17-23
Ratio of tensile strength to weight (equal area)	1	1.62
Ratio of tensile strength (equal conductance)	1	2.65
Ratio of tensile strength (equal temp. rise)	1	2.12
Elastic limit of % of tensile strength.....	75	70
Modulus of elasticity in lb. per sq. in.....	16,000,000	9,800,000
Modulus of elasticity in kg. per sq. mm.....	11,200	6,905
Specific resistance in microhms per cu. cm. at 60° F. (15.5°) soft.....	1.690	2.770
Specific resistance in microhms per cu. cm. at 60° F. (15.5°) hard.....	1.725	2.870
Specific resistance in microhms per cu. cm. at 0° C. (32° F.) soft.....	1.595	2.610
Specific resistance in microhms per cu. cm. at 0° C. (32° F.) hard.....	1.650	2.70
Resistance of conductor 1000 yd. long, by 1 sq. in. cross-section, soft.....	0.02398	0.03932

Ratio of weights for equal area.....	3.3	1.0
Ratio of weights for equal resistance.....	2.0	1.0

PICRIC ACID is obtainable from the gum-resins secreted by certain plants. Thus, aeoroid, black-boy, botany-bay, and grass-tree gums, yield picric acid upon treatment with nitric acid. This fact has not been utilized hitherto in a commercial way on account of the violence of the reaction, and the difficulty of controlling it, so as to secure a satisfactory output. Miller and Irlam have overcome this difficulty by treating the purified gum with limited amounts of acid, in the cold, or at temperatures not exceeding 40° C. Picric acid, nitro-phenol, and di-nitro-phenol are obtained by altering the quantity and temperature.

VIEWS IN NORTHERN IDAHO

Mining Districts of Northern Idaho

By E. K. SOPER

INTRODUCTORY. There are 150 mining districts in Idaho, but more than 90% of its metal production comes from the Coeur d'Alene region in Shoshone county in the northern part of the State. Northern Idaho, sometimes called the 'pan-handle,' embraces an area covering four counties: Boundary, Bonner, Shoshone, and Kootenai. Each of these counties contains ore deposits of importance, but until recently there has been little development outside of the well-established Coeur d'Alene region. However, within the past two or three years, prospecting and development operations have been extended to outlying districts in the Coeur d'Alene as well as to the northern counties generally, with the result that some promising mines and prospects have been opened.

TOPOGRAPHY. Northern Idaho is a region of steep-sided heavily-forested mountains, dissected by numerous deep-stream valleys. Several large lakes of glacial origin occur in the region, the most important being Lake Coeur d'Alene, Lake Pend Oreille, and Priest Lake. The main streams have eroded their channels to the approximate level of the Spokane valley. The elevations are not high as compared with those attained by the mountains farther east and south. The maximum relief is about 4000 ft., which also represents the topographic range of the outcrops of the veins. The surface, except on the steep slopes, is usually deeply weathered, and this, taken in conjunction with the heavy covering of vegetation, makes prospecting difficult over much of the area.

GEOLOGY. The principal formations of northern Idaho consist of Algonkian sediments comprising quartzite, argillite, and slate, with some thin layers of interbedded limestone. These rocks, known as the Belt Series, with

schists that probably represent their metamorphic equivalents, outcrop over a large part of northern Idaho and extend into Montana and British Columbia. The remaining part of the area consists chiefly of granite, probably of Cretaceous age, with associated gneisses and schists. Some of these gneisses may be of Archean age, since isolated areas of Archean gneiss are known to outcrop in numerous localities farther south. The granite is of the monzonite variety and outcrops over large areas in all four of the counties mentioned. It also occurs in smaller areas intruding the sediments of the Belt Series at many localities and probably underlies the sedimentary and metamorphic rocks throughout the entire region.

In addition to the granitic intrusives, the sedimentary rocks are cut by numerous basic dikes. These dike-rocks consist mostly of diabase or lamprophyre; they are associated with the ore deposits in nearly all of the mining districts in northern Idaho. There are no Paleozoic sediments in the northern end of the State, but in central and southern Idaho the Paleozoic rocks contain many important ore deposits. The only other formation, exclusive of glacial drift and Quaternary sand and gravel, that outcrops in this region is a patch of Tertiary lava, in the south-west corner of Kootenai county, where it represents the north end (in Idaho) of the great Columbia lava flow. This flow, or succession of flows, extends southward along the valley of the Snake river and covers the plains of eastern Washington and Oregon, as well as western and southern Idaho.

ORE DEPOSITS. The ores found in the four counties forming the 'pan-handle' include lead-silver, lead-zinc-silver, zinc, copper, gold, tungsten, and molybdenum ores, besides gold placers. The most important deposits

are the lead-silver, lead-zinc-silver, and zinc ores of the Coeur d'Alene. Most of the deposits and mines of the Coeur d'Alene have been described in detail by Ransome and Caulkins,¹ Hershey,² Umpleby,³ Bell,⁴ and others, and these descriptions need not be repeated here. However, there have been some recent developments in the Coeur d'Alene as well as elsewhere in northern Idaho that may be of more timely interest.

SHOSHONE COUNTY

The most important mining districts are the following: Wallace (Placer Center), Mullen (Hunter), Burke (LaLande), Kellogg-Wardner (Yreka), Evolution, Pine Creek, Slate Creek, Shoshone, Beaver, East Coeur d'Alene, Murray, and Bald Mountain (Monitor). The most important of these districts from the standpoint of production are the Wallace (Placer Center), Mullen (Hunter), Burke (LaLande), Kellogg-Wardner (Yreka), Pine Creek, and Beaver. Coeur d'Alene is a name frequently used to designate the region comprising all of these districts.

The Wallace district contains important deposits of both lead and zinc ores. The district embraces mines on Nine-mile creek from Wallace to Sunset, and the surrounding territory. The deposits within this area include some very complex ores. With the exception of the clean sphalerite ore of the Interstate-Callahan deposit, the ores usually consist of intimate mixtures of galena and sphalerite, with more or less pyrite, magnetite, and siderite. The galena always carries silver, but there is very little, if any, silver associated with the sphalerite. In some of the mines ore-shoots of comparatively clean galena are found, and in the Interstate-Callahan mine the ore consists of sphalerite, free from the sulphide minerals so common in the other deposits of the district. Where galena and sphalerite occur together, the two minerals are often in such close association that the finest grinding is required to break the association. The association is rendered still more refractory in some mines by the addition of pyrite, and by the presence of much siderite in the gangue. The principal mines of the Wallace district include the Interstate-Callahan, Tamarack and Custer, Rex, and Success. All of these supply large mills, and since the introduction of flotation the recoveries have been greatly increased.

The Mullen (Hunter) district includes the town of

Mullan, about seven or eight miles east of Wallace, on the branch of the Northern Pacific railroad connecting Wallace with Missoula, in Montana. The ores of this district contain less zinc than those in the Wallace district. Lead-silver ore is the principal product, and the district contains some of the most important lead-silver mines in the Coeur d'Alene region. There is also an important copper mine, the National, which is now under active development. The famous Snowstorm copper mine, now worked out, was also near Mullan. The principal active mines are the Morning, Gold Hunter, and National. An important property still in the development stage is the Star, now engaged in litigation with the Morning mine of the Federal Mining & Smelting Co. The Morning ore contains considerable sphalerite associated with the galena in a heavy gangue of siderite. Some barite and quartz is also present, and pyrite and pyrrhotite also occur associated with the lead and zinc sulphides. The silver is associated with the galena. Considerable quantities of oxidized lead-silver ore were found in the old upper levels of the Morning mine, and it has been reported recently that additional bodies of lead carbonate have been found in developing new ground on the upper levels. Because of the association of considerable zinc sulphide with the argentiferous galena in the Morning and Gold Hunter ores, and because of the presence of large amounts of siderite in the gangue, these ores have presented serious milling difficulties, now successfully overcome. The mines in the Mullan district were among the first to employ selective flotation.

The mines in the Burke (LaLande) district are nearly all situated along Canyon creek in the Burke canyon, which joins the south fork of the Coeur d'Alene river at the town of Wallace. The ore deposits occur at intervals along the canyon between Wallace and Burke, the most important being at Burke, which town is well known from the fact that the famous Hercules and Hecla mines are there. The deposits consist of replacement veins occupying fault-fissures in Burke quartzite, and in their main geological features are similar to the type prevailing throughout the Coeur d'Alene region. The ore consists chiefly of argentiferous galena, comparatively free from zinc sulphide. Recently, however, some ore consisting of a mixture of sphalerite and galena was found in the Oronogo vein of the Hecla mine. This lead-zinc ore is now being milled separately, so as not to mix with the clean lead-silver ore which constitutes the bulk of the output of the Hecla. The Hercules ore has always been noted for being exceptionally high in lead and silver and remarkably free from zinc. Some of the richest stopes ever opened in the Coeur d'Alene are being worked in the Hercules mine, and although the property has been developed to considerable depth, very little zinc sulphide has yet been encountered. In addition to the Hercules and Hecla mines, the Burke district also includes the Green Hill-Cleveland, Frisco, Marsh, Blackbear, Gertie, Oom Paul, and other properties.

The Kellogg-Wardner (Yreka) district embraces the

⁴Origin and Distribution of Ore in the Coeur d'Alene," Pamphlet, M. & S. P., San Francisco.

⁵Umpleby, J. B. "Genesis of Success Zinc-Lead Deposit," "Economic Geology," Feb.-March, 1917.

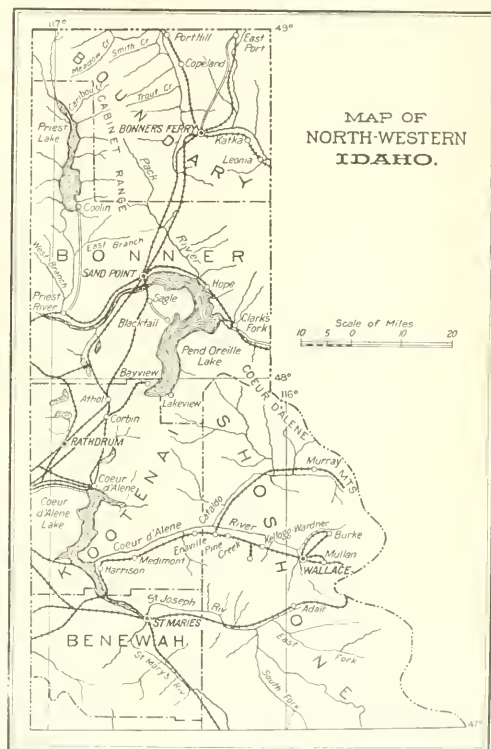

⁶Bell, Robt. N. Annual Reports of State Mine Inspector, Boise, Idaho.

region surrounding the towns of these names, and includes the famous Bunker Hill & Sullivan mine. The ore is chiefly argentiferous galena, very little zinc having as yet been found in any of the mines of this district. Like most of the other deposits of the Coeur d'Alene, these consist of metasomatic veins in pre-Cambrian sediments along fault-fissures. Some of the deposits contained rich oxidized silver-lead ore near the surface. The Bunker Hill & Sullivan vein is said to be the one vein in the Coeur d'Alene that showed a prominent outcrop. The ores of this district are less complex and easier to mill than most of those in the Coeur d'Alene. During the summer of 1917, the Bunker Hill & Sullivan company completed its new lead smelter, at which custom work will also be done, at Bradley, near Kellogg. Suit has been brought by the A. S. & R. Co. to prevent the Bunker Hill company from smelting its ore. The existence of a custom lead smelter in the heart of the Coeur d'Alene will be of special benefit to the operators of small mines. Some years ago one of the most productive veins in the Kellogg-Wardner district was lost at a fault intersection, and all subsequent attempts to recover the faulted segment of the vein have failed. Recently operations have been started to explore the ground under and adjacent to the town of Wardner in an attempt to find a continuation of this vein, and of other rich ore deposits formerly worked in the vicinity. The principal mines of the district are the Bunker Hill & Sullivan, Caledonia, Stewart, and Last Chance. The Sierra Nevada and the Alhambra have recently reached the producing stage.

The Pine Creek district is new and important. The district embraces the region included within the drainage basin of Pine creek and its tributaries, a distance of 12 to 15 miles. A branch line of the O. W. R. & N. is now being constructed up Pine creek. The ore deposits are replacement veins occupying fault-fissures or shear-zones in the Prichard slate. The veins are associated with basic dikes. While they resemble the other veins of the Coeur d'Alene in their broader geologic relations, they differ from the lead-silver veins in many respects, as, for instance, in the general occurrence of a fine-grained intimate mixture of sphalerite, galena, and pyrite in the typical ore; the fact that the ore deposits are confined to the Prichard slate; the frequent absence of well-defined walls; and the more frequent occurrence of the ore in shear-zones. The principal mines of the district are the Constitution, Highland-Surprise, Hypotheek, Nabob, Douglas, Northern Light, and Amy Matchless groups. Most of these properties have been making regular shipments for some time in spite of the handicap of a long wagon-haul over bad roads to the present shipping point on the Wallace branch of the O. W. R. & N., the nearest point of which is at the mouth of Pine creek. In addition to the lead-zinc-silver ores just mentioned, this district contains two productive antimony properties, the Star Antimony and the Coeur d'Alene Antimony mines. It is only within the last year or two that this district has come into prominence as a producer,

although the presence of veins in this locality has long been known. During the past year the Anaconda Mining Co. has been purchasing local ores for treatment at its Great Falls plant. The district owes much of its present activity and bright future to the fact that its complex ores have found a market.

The Beaver district likewise has only recently reached the production stage. It has been known for some time that ore deposits existed on Beaver and Carbon creeks and their tributaries, but owing to the complexity of these ores, and the absence of a market for the impure

concentrate, the deposits have remained undeveloped. Recently the introduction of flotation and the general improvements made in milling ores of this type, together with the construction of a custom zinc plant by the Anaconda company to treat impure zinc concentrate, have made it possible to exploit these ores at a profit. This district may be most easily reached from the Murray branch of the O. W. R. & N. During the year a branch line of the O. W. R. & N. has been completed up Beaver creek to Carbon station. A spur of the railroad has been extended to the Ray-Jefferson mill. The ore deposits are similar to those of Pine creek. The veins have been formed partly by replacement of the sheared slate, and partly by fissure-filling. It is difficult to determine the true walls of the veins because of several parallel slip-planes, which are frequently accompanied by much

gouge. The ore occurs as seams, bands, and lenses in the sheared slate. The ore contains sphalerite with a subordinate amount of argentiferous galena, with which is associated much pyrite, and sometimes a little gold. The typical ore is an intimate mixture of the sulphides, requiring extremely fine grinding. The principal mines are the Ray-Jefferson, Idora, Tuscumbia, and Red Monarch.

The Evolution district includes the Big Creek watershed and some territory on the north side of the south fork of the Coeur d'Alene river. The district lies half-way between Osborn and Kellogg on the O. W. R. & N. The principal prospects are the Polaris, Yankee Girl, Yankee Boy, Western Star, Trojan, Silverado, and Rhode Island. Considerable exploration and development work is under way, but as yet no important producing mines have been developed.

The Shoshone district, which lies 15 miles south-west of Paragon and 5 miles east of Murray, is reached by the Murray branch of the O. W. R. & N. through Enaville. The principal mines and prospects are the Terrible Edith, Monarch, Paragon, Black Horse, Bear Top, and Orofino. Development work has been under way at most of these properties during 1916-1917, and considerable ore has been shipped from the district in the past.

The Slate Creek district, which lies 15 miles south of Wallace, is one of the most inaccessible in the Coeur d'Alene. It is reached by trail from Wallace. The geology is similar to that prevailing throughout the Coeur d'Alene. The sediments are intensely folded, and faulting is in great evidence. Intrusives are numerous. At the present time there are no producing properties in this district, but there are many prospects and considerable development work is being done.

The East Coeur d'Alene district lies on the outskirts of the Coeur d'Alene region. It is reached from St. Joe on the Chicago, Milwaukee & St. Paul railroad. The ore deposits consist of veins in brecciated zones along fissures in Algonkian sediments, chiefly quartzite. Copper ores predominate, the chief minerals being bornite and chalcopyrite. The deposits generally have heavy gossans. The Black Prince is probably the best known of the properties in this district.

The Bald Mountain (Monitor, St. Regis) district is outside the area usually included within the Coeur d'Alene region. It lies in the Bitterroot mountains and extends into Montana. The district is reached from Saltese, Montana, or from Lookout, both stations on the Northern Pacific railroad. The Chicago, Milwaukee & St. Paul railroad also touches this district. The ore deposits, which are veins along fault-fissures, are valuable for copper. The ores carry about 0.02 oz. gold to 1% of copper. The principal mineral is chalcopyrite. The most important mines are the Richmond, Monitor, and Bald Mountain. Other properties are the Buffalo, Park, Springfield, Champion, Eagle, Bullion, North Star, Alpino, and Leroy. The mineral deposits lie in a belt along both the eastern and western slopes of the Bitterroot divide, which forms the Montana-Idaho boundary.

The Richmond is now being worked and has recently attracted considerable attention. Several of the other properties in the district were actively developed during the past summer.

The Murray district is the oldest in the Coeur d'Alene and has been known chiefly for its production of gold. It includes the ground surrounding the town of Murray on the north fork of the Coeur d'Alene river, and is reached through Enaville by a branch of the O. W. R. & N. The country-rock consists of pre-Cambrian sediments cut by intrusives. The chief ore deposits are veins in Prichard slate. The erosion of the gold-bearing veins has resulted in the formation of numerous placer deposits, and it was these gold placers that first attracted the attention of prospectors to the Coeur d'Alene. During recent years there has been very little activity in the Murray district. The placers have been largely worked out and the remaining gold ores have proved too low-grade. During the past year the old Golden Chest mine was re-opened in an attempt to mine the ore remaining on the lower levels. The effort proved unsuccessful so far as the gold was concerned, but a considerable quantity of rich tungsten ore, consisting of scheelite in quartz, was found in cross-fissures associated with the main vein of auriferous pyrite. A considerable quantity of tungsten ore was also found broken in the old stopes. This ore was concentrated and shipped, but the scheelite proved to be pockety and the mine has again become idle. During the past summer, following extensive explorations by churn-drilling, the Yukon Gold company has begun the construction of a large dredge to work the gravel of some of the tributaries of the North fork. The construction of this dredge is now well under way. The preliminary drilling is said to have demonstrated the existence of a large area of gold-bearing gravel. The Empire copper mine on the Little North fork of the Coeur d'Alene river, near Enaville and west of the Kellogg-Wardner district, has been a continuous producer during the past year. This mine was equipped with a 150-ton mill, which, according to reports, has recently been enlarged. The vein is opened by three adits and long ore-shoots have been exposed on several levels. The ore is said to carry 3 to 5% copper.

With respect to the Coeur d'Alene region as a whole, it may be said, in summary, that the developments for the past two years have been highly satisfactory. While some of the big rich ore-shoots that have supplied so much of the past production are rapidly approaching exhaustion, new orebodies are being developed to take their place, although some of these ores are more refractory. Not only have there been important new discoveries of zinc ore, but some of the biggest and richest bodies of galena ever known in the Coeur d'Alene are being mined at the present time. The great importance of the Prichard slate as an ore-bearing horizon has been demonstrated beyond doubt, and while the ores found in this formation are usually complex and low-grade, they will doubtless insure a considerable extension to the productive life of the region.

KOOTENAI COUNTY

There are only three mining districts in this county, and none of these are important producers at this time.

The Medimont district, reached from Medimont station on the Wallace branch of the O. W. R. & N., contains silver-lead ores in veins in Algonkian sediments. None of these deposits have been developed to any extent and little information is available concerning the prospects.

The Canas Cove district in the south-eastern corner of the county produces a little placer gold. The most important enterprise is that of the Tyson Consolidated company. This company has expended considerable capital in equipping a hydraulic mine.

The Lakeview district in the extreme north-east corner of the county comprises a small area around the south shore of Lake Pend Oreille. Only the extreme south end of the district lies in Kootenai county. The Lakeview district lies chiefly in Bonner county.

BONNER COUNTY

The Lakeview district lies along the south-east shore of Lake Pend Oreille and is reached from Sandpoint at the north end of the lake, or from Bayview from the south end, by boat to Lakeview landing. Both Sandpoint and Bayview may be reached by railroad from Spokane. As yet there is no railroad tapping the district. The principal geological formation outcropping in the district is the Newland. This is probably the equivalent of the Wallace formation of the Coeur d'Alene. It consists chiefly of slates but contains some quartzites and a little limestone. Acidic intrusives (chiefly monzonite) occur within a few miles of the ore deposits. The sedimentary formations are cut by numerous faults. The ore deposits consist chiefly of veins in the sedimentary rocks. They are associated with narrow basic dikes. The ore contains lead and silver with zinc. The zone of oxidation is shallow. Typical ore consists of a complex mixture of argentiferous galena, sphalerite, and pyrite. The pyrite carries a little gold and silver. Some copper sulphides, chiefly chalcopryite, also occur associated with the lead and zinc sulphides. The principal mines are the Webber, Keep Cool, Venezuela, Conjecture, Rainbow, Spider, Silver Cord, and Swastika. During the past year some high-grade hand-sorted ore was shipped from the Venezuela, and development work was carried on at several other properties. None of the mines operate mills. The Webber mine formerly had a mill, but it was never operated successfully. This mill, which has been idle for years, burned down last summer. The district contains some strong veins carrying considerable milling ore in addition to the first-class ore that has been taken from the upper levels. Most of the properties have not been developed more than a few hundred feet below the surface. It is probable that systematic development would result in opening up important bodies of ore of milling grade, and were it not for the lack of transportation facilities, this district would probably be an important producer at the present time.

The Blacktail (Pend Oreille) district includes Black-

tail mountain and the surrounding area on the western shore of Lake Pend Oreille, and may be reached either by boat from Bayview and Sandpoint, or by a wagon-road from Sagel station on the Northern Pacific railroad, five miles north-west of Blacktail. The general geology of the district is similar to that of Lakeview on the opposite shore of the lake. The ore deposits consist of veins occupying fault-fissures in sedimentary rocks. Although there are a number of important prospects in the district, the Armstead mine is the only important property at the present time. The Armstead shows a clean-cut vein from three to four feet wide and occupying a fault-fissure in quartzite and slate. The vein strikes north and south; dips 43° east, and cuts the bedding of the sedimentary rocks at a small angle. The ore consists of a mixture of galena, tetrahedrite, and argentite, with some chalcopryite and native silver, in a quartz-siderite gangue. Many inclusions of country-rock occur within the vein. This property, which was formerly known as the Keystone mine, was recently taken over by Henry H. Armstead, and consolidated with a large group of adjoining mining claims. It is being developed in a systematic and thorough manner. Already large bodies of ore have been exposed and at least 70,000 tons of lead-silver ore are reported blocked out on the upper levels, which, in addition to the lead and zinc content, is said to contain from 30 to 50 oz. of silver and 0.16 oz. gold per ton. The company intends to build a modern concentrating mill as soon as the mine has reached the desired state of development. During the late summer and fall some records in fast driving were made at this property while advancing the lower adit, which is to serve as the main working-level. In 31 days from the end of November the adit was advanced 544.8 ft. This lower adit, which is already in 2858 ft., is being driven to intersect the main vein, which it is expected will be cut 542 ft. beyond the present face. The adit will probably be extended a considerable distance beyond this point to cut other parallel veins known to exist. The total depth to be obtained on the Armstead vein by this adit will be about 1600 ft. and an additional 500 ft. of depth can be obtained by driving a lower adit slightly above the level of the lake. The results of these operations are being watched with keen interest by all those interested in the Blacktail and surrounding districts, since this is the first attempt at deep development to be made on any of the properties in northern Idaho outside the Coeur d'Alene region.

The Clark Fork district includes the region surrounding Clark Fork station on the Northern Pacific railroad near the point where the Clark Fork river joins Lake Pend Oreille. The district extends back for several miles on both sides of the river, and includes a large number of prospects. Most of the properties, however, are on the north side of the Clark Fork. The ore deposits consist of veins in slate and quartzite and in their general relations are similar to those of the Coeur d'Alene. The ores consist mostly of argentiferous galena in a quartz-siderite gangue. There are also several deposits of cop-

per ore carrying chalcopryite as the dominant ore-mineral. The principal mines and prospects include the Lawrence, Copper Giant, Clarinda, Hidden Treasure Group, and Lucky Strike. The Lawrence mine, which is reached by good wagon-road $1\frac{1}{2}$ miles east of Clark Fork, is being operated on a small scale. The mine, which has been only slightly developed, contains a vein of argentiferous galena in a ripple-marked quartzitic slate. The property is equipped with a 50-ton mill, and is making a high-grade lead concentrate containing from 11 to 15 oz. silver per ton. None of the other properties in the district has been developed beyond the prospect stage. The Lawrence is the only mine at which a mill has been erected. Some of these prospects, however, exhibit excellent surface showings. At the Copper Giant mine, $3\frac{1}{2}$ miles west of Clark Fork, a 3-ft. vein showing chalcopryite, bornite, and cuprite in a quartz-siderite gangue has been exposed in several short adits. At the Clarinda mine, which adjoins the Copper Giant, a similar vein has been opened. However, at this property the copper mineralization near the surface gave place to argentiferous galena at a shallow depth.

The Hope district adjoins the Clark Fork on the north-west and includes the country on the north-east shore of Lake Pend Oreille in the vicinity of the town of Hope, on the Northern Pacific railroad. The geology is similar to that of Clark Fork. Granitic intrusives are prominent in the vicinity of Trestle creek near Hope. The principal properties are the Marguerite, El Paso, Rebecca, Black Bear, Big Five, Park River Mining Co., and the Morning Star. All of these except the Morning Star are in the drainage basin of Trestle creek. None of them is beyond the prospect stage. The deposits include ores of lead, silver, copper, and gold, and some of the more promising veins are under active development during the past summer.

The Priest Lake district includes the region surrounding Priest lake in the extreme north-west portion of Bonner county. The principal settlement is Coolin, on the south shore of Priest lake, 25 miles north of Priest River station on the Great Northern railroad. The district is reached by wagon-road from Priest River. The ore deposits consist of veins in pre-Cambrian sediments associated in places with granite. The area of the district is large and the geology is imperfectly known. There are no producing mines at the present time, although several promising prospects are being developed. In addition to these prospects a large number of claims have been staked and upon these annual assessment work is being done. The deposits consist chiefly of lead-silver ores, but copper-bearing veins carrying some gold also occur in the district.

BOUNDARY COUNTY

The Porthill district is in the extreme north-west corner of Idaho, along the British Columbian boundary. It is reached from Porthill, Idaho, a station on a branch of the Great Northern railroad. The geological formations consist of pre-Cambrian sediments associated with

granite and granite-porphry intrusives. Basic dikes also cut the sediments. Quartzite, which resembles the Burke quartzite of the Coeur d'Alene, is the typical country-rock in the vicinity of the Idaho-Continental mine. The ore deposits occur as replacement veins in the sedimentary rocks associated with diabase dikes, and in many respects resemble veins of the Coeur d'Alene. The Idaho Continental mine, operated by A. Klockmann, is the most important mine in the district and ranks as one of the chief producers in Idaho outside the Coeur d'Alene. The property is reached by an excellent auto-truck road, 26 miles long, constructed by the Idaho-Continental Mining Co. at a total cost of \$130,000 in order to deliver concentrate and ore to the railroad at Porthill, which is the nearest shipping point. The ore deposit of the Idaho-Continental mine consists of a sheeted zone 10 to 20 ft. wide in quartzite. The shattered quartzite is replaced by silver-bearing galena, which occurs as numerous stringers and seams alternating with bands of partly replaced quartzite. Some quartz filling was noted especially in the upper levels, but the deposit is essentially of the replacement type. The ore consists of argentiferous galena, which carries about $\frac{1}{2}$ oz. silver per unit of lead. Large amounts of pyrite are associated with the galena. The ore is practically free from sphalerite and the concentrate contains only about 2% zinc. A little chalcopryite is associated with the galena and pyrite, but not in commercial quantity. The mine has recently constructed a new mill of 150-ton daily capacity to take the place of the mill that was burned down not long ago. The mill is equipped with the necessary crushing machinery, picking belt, jigs, and tables. The company intends to add a flotation plant. The mill-ore averages from 10 to 12% lead. Considerable first-class ore carrying 50% lead and 20 to 25 oz. silver per ton is shipped direct. The ratio of concentration is about 8.6:1. The concentrate is transported to Porthill by auto-truck, and during the past summer and fall, eight or nine trucks were kept in continuous operation. Because of the fact that the concentrate is high in lead and iron and relatively free from zinc, it is in demand at the smelters. There are several promising prospects in the region surrounding the Idaho-Continental property, but little development work has been done on any of them. The area included in the district is large, and has been thoroughly prospected. In addition to the prospects west of Porthill, in the vicinity of the Idaho-Continental mine, there are other properties in the district upon which some development work is being done. Among these may be mentioned the Golden Sceptre (copper-silver) near Porthill; the North Star group (lead-silver) near Porthill; the American Girl group (molybdenum); the Blanche group (gold, silver, lead); Dora group (tungsten); and the Rosie D., all near Copeland.

The Moyie Yaak district is about 19 miles north-east of Bonners Ferry and may best be reached from that point. The ore deposits occur as veins and sheeted zones in pre-Cambrian sediments of the Belt series associated

with intrusives. The ores are valuable for lead, silver, and gold. The district contains a number of prospects and small mines upon which some development work has been done. In addition, there are many others on which only assessment work is being done. There are as yet no important producing mines in the district, but this is probably due to its isolation and the lack of transportation facilities. The country has been only superficially prospected and offers excellent opportunities for discovery. A branch of the Canadian Pacific railroad passes through this district, and if good wagon-roads were available, it would not be difficult to secure a shipping point for the ores. The best known property is probably the Buckhorn mine, situated in the rugged mountains along the Moyie river, and about 10 miles north of Kootenai river. A wagon-road connects this mine with the main road along the Kootenai. This property, at which more than 2000 ft. underground work has been done, is equipped with a 5-stamp mill, and is producing lead-silver ore that carries some gold. Other properties in the district include the Copper Falls, $2\frac{1}{2}$ miles east of Eastport; Moyie Gold-Copper Mining & Milling Co.; and the Moyie hydraulic mine.

The Katka-Leonia district is east and a little south of Bonners Ferry along the main line of the Great Northern railroad in the vicinity of Katka and Leonia stations. The district may be reached from either of these stations or by wagon-road from Bonners Ferry. The Katka silver-lead mine and Idaho-Montana mine (also a silver-lead deposit) both near Katka station, have done some development work recently and have produced some ore. Near Leonia, the Idaho Gold & Ruby Mining Co. is erecting a plant for hydraulic operations on a deposit of gold-bearing gravels. Another property at which some development work has been done recently is that of the Idaho Copper Mining Co., also near Leonia. The mountains throughout this area contain abundant evidence of mineralization, but prospecting is rendered difficult by the heavy covering of vegetation. Numerous prospects have been located in addition to those just named, but at most of these only assessment work is being done. The whole region included within Boundary county shows evidence of mineralization, and numerous veins outcrop. The country is exceedingly mountainous and the canyon slopes are steep and heavily forested. This condition, in conjunction with the inaccessibility of much of the area, has made prospecting difficult and has retarded development. However, the region is one of promise, and it is not unlikely that several producing mines may be developed here within the next few years.

THE VALUE of the mineral production of Alaska in 1917 is estimated at \$41,760,000, exceeding that of any previous year except 1916, which was \$48,632,000. The decrease in 1917 was therefore about \$6,870,000. During 33 years Alaska has produced over \$391,000,000 worth of gold, silver, copper, and other minerals. Of this amount \$293,000,000 represents the value of the gold, and \$88,200,000 that of the copper.

Antimony in Humboldt County, Nevada

Antimony is one of the necessary war minerals for which the United States is dependent on foreign countries. In view of the desirability of having information on all possible domestic sources of antimony, the Arabia mining district, in Humboldt county, Nevada, has recently been examined by a geologist of the U. S. Geological Survey. This mining district, long idle after its first period of activity in the late 'sixties, has become active again. The pioneer smelter in Nevada, at Oreana, on the Central Pacific railroad, was built in 1865 to reduce the ore of the Montezuma mine in the Arabia district. The ores are notable in that they consist almost wholly of silver-bearing bindheimite, the so-called hydrous antimonate of lead. None of the orebodies has been explored to a vertical depth greater than 200 ft., and the zone of unaltered sulphides has nowhere been reached. The primary ores were formed under high temperatures by 'deep-seated' mineralization. In view of this origin, some of the stronger veins may carry ore in depth. This possibility, together with the change that a lower zone of enriched silver sulphides exists, suggests that the district merits deeper exploration than has yet been attempted. The principal use of antimony in war is to harden the lead in bullets.

TESTS to determine the influence of small amounts of copper in steel have recently been reported by Carle R. Hayward and A. B. Johnston, in the bulletin of the American Institute of Mining Engineers. They confirm the findings of previous investigators, as follows: E. J. Ball states that copper increases the tensile strength and hardness but lowers the elongation; J. E. Stead states that copper-steels closely resemble nickel-steels containing equivalent percentages of nickel as regards tensile strength, resistance to shock, corrosion, and hardness; F. H. Wigham found that copper in small amounts had no injurious effects on steel; P. Breuil found that, with 1% carbon, copper lessened the brittleness of steel, and in low-carbon steel it increased the tensile strength and lowered the ductility slightly; and H. H. Campbell states that copper up to 0.25% slightly raises the elastic limit, elongation, and reduction of area.

BUYERS of zinc concentrates for the smelting companies, as stated by H. G. George, in a contribution to the A. I. M. E., purchase on a base of 60% metallic zinc in the concentrates. They penalize \$1 per unit of zinc below 60% and they pay a premium of \$1 per unit of zinc above 60%. Iron is penalized at the rate of \$1 per unit over 1%, lime is penalized 50c. per unit over 2%, and lead is penalized \$1 per unit over 1%. This scale of penalties and premiums usually applies to concentrates containing from 50 to 63% metallic zinc. For ores of a lower grade a different scale is used. Some ores are purchased on contract deducting a fixed smelting charge from the value of the metallic zinc content of the concentrates.

Pressure in the Formation of Ore Deposits

By STEPHEN TABER

As early as 1836 Weissenbach¹ assumed the existence of a 'force of crystallization' in order to explain the peculiar occurrence of certain crystals of pyrite and arsenopyrite. Later, Laval² noticed that a crystal growing on the bottom of a glass dish may raise itself because of the addition of new material to its supporting edges. This observation opened a wide field for investigation, but unfortunately it was almost entirely neglected for many years. Even today few geologists recognize the importance of the fact that crystals may grow in directions in which growth is opposed by adjacent solid bodies. During the last four years I have been conducting a series of experiments with the two-fold purpose of determining the conditions under which growing crystals may exert pressure against other solid bodies, and of producing veins in the laboratory where the origin and development of their structural features could be observed in detail. Most of these experiments have already been described;³ therefore only a brief summary of some of the results and conclusions is necessary in this place. A number of salts have been used, their precipitation being brought about by cooling, by evaporation, and by the mingling of two solutions differing in composition; glass containers have been broken during crystal-growth, and nearly all of the vein structures found in nature have been successfully duplicated.

There is really nothing remarkable in the growth of a crystal under external pressure; all crystals have been formed under some degree of pressure, and it is obviously impossible to grow crystals in a vacuum. When the material for crystal-growth is obtained from a solution, the crystal will continue to grow as long as its surfaces are in contact with the super-saturated solution. If any portion of the surface of a crystal is not in contact with solution, or if the solution is not super-saturated with respect to that surface, no addition of new material to that portion of the crystal will be made, although the crystal may develop in other directions. Concentration of the solution in contact with a growing crystal is maintained by circulation and diffusion through the solution.

increase of pressure, and, therefore, the greater the pressure the greater must be the concentration of the solution. The solubility of most substances increases slightly with solution in order that crystal-growth may take place. When a crystal pushes a foreign body aside, it is due to the fact that the material necessary for growth is able to diffuse between the growing crystal and the foreign body. In Laval's experiment the lifting of the crystal occurred because there was present, between the crystal and the bottom of the glass, a thin film of solution, which was not expelled by pressure; it was by diffusion through this solution that additional material reached the supporting surface of the crystal. If two absolutely smooth parallel surfaces are separated by a drop of liquid that wets them both, capillarity tends to bring the two surfaces close together and to reduce the thickness of the separating film of liquid to a minimum. It is improbable that this film of minimum thickness, which may be no greater than the diameter of the space occupied by a single molecule of the liquid, can be completely expelled by capillarity, or even by external pressure that does not rupture the solids. It has been suggested that, under certain conditions, diffusion may take place directly through individual crystals, though this seems doubtful. However, fluids can certainly penetrate between the most closely associated crystals, and it appears probable that two crystals are never in such close contact that their respective atoms along the contact may not be more widely separated than they are within either crystal. Microscopic examination has proved that it is possible for solutions to penetrate between the mineral grains of even the most compact rocks and bring about important alterations and replacements.

In the course of my experiments two types of veins were obtained; one fibrous, with the fibres transverse to the walls, and the other crystalline with the individual crystals anhedral and approximately equi-dimensional. Fibrous veins (Fig. 1) were formed when the material for vein-growth was supplied through solutions occupying small closely-spaced capillary openings in the walls, while non-fibrous veins were formed when the vein-forming solutions circulated between the walls. With both types, the growing veins made room for themselves by forcing the enclosing walls. In these experiments vein-growth was slow, averaging about 0.2 mm. per month, and diffusion played an important part in the transportation of the vein-forming material. By changing the composition of the solutions banded veins were obtained. Some of the veins were branching, and frequently they contained inclusions of the wall-material. Opposite walls were approximately parallel when they

E., No. 119, Nov. 1916, pp. 1973-1998; 'Pressure Phenomena Accompanying the Growth of Crystals,' Proc. Nat. Acad. Sci., Vol. 3, 1917, pp. 297-302.

consisted of rigid material; lenticular veins (Fig. 2) were obtained when the walls, under the conditions of the experiment, were of flexible material.

Through the study of metalliferous veins, and especially of some of the simpler, though commercially unimportant, veinlets, found in regions of unaltered sedimentary rock, much evidence has been secured tending to prove that many veins were not formed by deposition in open fissures, but that the growing veins have forced apart their walls in the same way as was done by the veins produced in the laboratory. The miner who has

FIG. 1

had difficulty in supporting the walls of a vein must often wonder how the fissures could have remained open during the long period of time necessary for the deposition of the ore, and he should more easily comprehend a theory of vein-formation that does not require such im-

FIG. 2

probable assumptions. Ever since, as a student working in one of the deeper mines of the Mother Lode district in California, I had opportunity to observe the struggle to maintain openings in shattered ground while the ore was being extracted, I have been looking for a more adequate theory of vein-formation than those generally held in the past. Open fissures, comparable in magnitude to the many barren and metalliferous veins, are not known today at any place on the surface of the earth; and there is no reason for assuming that they existed during earlier geological periods. Of course, this argument does not apply to the replacement theory of vein-formation, but many veins have well-defined walls that show little or no evidence of replacement.

Banding, vugs, and comb-structures are commonly cited in text-books on ore deposits as proof of the deposition of veins in open fissures, but these structures are relatively rare. Moreover, as previously stated, all of

these structures have been reproduced in the course of my experiments. In fact, it was extremely difficult to prevent the formation of vugs during the relatively rapid growth of the veins produced in the laboratory, where it was impossible to maintain absolutely uniform conditions. These vugs were due to a local deficiency of material necessary for growth, because of insufficient concentration or relative inaccessibility. If veins were formed through the gradual deposition of mineral on the walls of open fissures until the filling was completed, there should be a suture line near the centre where the opposite sides meet, but most veins show no evidence of such a structure, and in many small veins individual

FIG. 3

crystals may be found extending from wall to wall. This is frequently true in the case of cross-fibre veins, and sometimes these veins show symmetrical shading or color-banding in such a way as to indicate that additions have been made to the fibres simultaneously at both ends.

Most veins are more or less lens-shaped, and this form is frequently accentuated, especially where the wall-rock is a highly laminated schist, slate, or shale, conforming in strike and dip with the vein. Sometimes the lenses are remarkably symmetrical, and again they may be quite irregular; in extreme cases they are bulbous, or almost spherical. Near such veins the planes of bedding or of schistosity usually conform closely to the curvature of the lenses in such a way as to prove that the walls have been slowly pushed apart by some force acting from within. It has been suggested that some lenticular veins may be igneous intrusions, while, according to another theory, the vein-forming solutions were under such heavy pressure as they ascended toward the surface that they were able to force apart the walls of small fractures and thus form the receptacles in which their load was deposited. There are many facts that argue against both of these theories, and it is obvious that neither is appli-

cable to lenticular veins of calcite formed near the surface in unaltered shales and limestones. If the enlargement of the vein-spaces was due to the pressure of fluids, very flat, lenticular, or tubular-shaped openings would be formed rather than a series of thick lenses connected by thread-like veinlets that in places are microscopic in size. Moreover, unless the spaces were immediately filled by the deposition of ore, the pressure of the fluid would have to be uniformly maintained in order to prevent collapse of the walls. Another argument against these theories is the presence within the veins of detached fragments of the wall-rock that have been only slightly displaced from their original positions. The gold-quartz veins of the southern Appalachian region are commonly lens-shaped, and some of them contain inclusions of the wall-rock which have reached their present positions with little rotation, for the schistosity of the inclusion is approximately parallel to that of the neighboring walls.

One of the best arguments supporting the theory that growing veins have made room for themselves is furnished by the presence in them of inclusions of the country-rock. In some of the simpler veins, where replacement has not been active, it is often possible to find on a wall the exact place from which a given fragment has been detached (Fig. 3), as the two surfaces would fit perfectly together if placed in contact. Some ore deposits are made up largely of angular rock-fragments, slightly separated from each other and cemented by vein-matter; and every gradation may be found between such breccia-veins and ore deposits that consist of a mass of reticulated or branching veinlets ramifying in all directions through the partly mineralized country-rock.

Pressure exerted during crystal growth is also believed to play an important part in the formation of many replacement deposits. When a crystal of an ore-mineral in growing exerts pressure upon the minerals forming the country-rock, they may be forced into solution if their solubility is increased by pressure, thus making room for the enlargement of the replacing mineral. The solubility of most substances is increased by pressure, and the study of minerals under the microscope indicates that, in some instances, minerals have gone into solution where the pressure was greatest, and have precipitated again where the pressure was least. Pseudomorphs of one mineral after another, which are found in some ore deposits, indicate that some chemical interchange between the two substances has taken place, or that the solution of the replaced mineral brought about changes in the composition of the ore-bearing solution that resulted in the precipitation of the replacing mineral. On the other hand, calcite is frequently found completely replaced by pyrite, galena, and other sulphide minerals, exhibiting well-developed crystal-form, and showing absolutely no evidence of inherited structure. It seems probable that replacement in some cases has been as much a physical as a chemical process.

In a brief paper it is possible to discuss only a few of the many facts supporting the view that forces which have developed during crystal-growth have been an in-

fluent factor in making room for the deposition of ore-minerals. Sufficient has been said, however, to indicate that this process is of the utmost importance in the formation and enlargement of many orebodies.

By way of conclusion, a brief outline of my conception of the way in which most veins have been formed is here presented. It is believed that most veins have been deposited from solutions, mostly of magmatic origin, ascending under great pressure and at a high temperature; these solutions have penetrated slowly along the lines of least resistance, such as faults, planes of bedding or schistosity, or through porous strata. Where there were appreciable openings they have been filled; but it is improbable that extensive deposits have been formed at any considerable depth below the surface solely through the filling of open cavities. As the minerals crystallized from solution, they have exerted pressure on the enclosing rocks, thus tending to enlarge the space surrounding the growing deposits. In some cases the minerals of the country-rock have been rendered more soluble by the pressure and have been removed in solution. In most replacement deposits, however, it is probable that chemical interchange between the ore-bearing solutions and the country-rock has been an important factor. The transfer of material for crystal-growth through the extremely small openings between the crystals is probably more often due to diffusion than to circulating solutions. Cross-fibre veins have been formed through a process of lateral secretion, the material for vein-growth having reached the veins through capillary and sub-capillary openings in the walls.

LOUIS M. DENNIS, of Cornell University, has recently devised a cyclic method for the manufacture of phenols from aromatic hydrocarbons, which is naturally applicable to the production of a large number of the hydroxyl derivatives of aromatic hydrocarbons. Benzene is treated with sulphuric acid, preferably fuming acid, to produce benzene-sulphonic acid in excess of sulphuric acid. This mixture is treated with benzene. As the sulphuric acid is practically insoluble in benzene, the latter takes up the benzene-sulphonic acid, but not sulphuric acid to any extent, forming a benzene solution of benzene-sulphonic acid, substantially free from sulphuric acid. This is treated with water, which dissolves the benzene-sulphonic acid and separates it from the benzene. The reactions are substantially as follows:

THE principle of the solenoid has been applied by C. M. Mullan, of Portland, Oregon, for lifting stamps in a stamp-mill. The object is to avoid the loss of power through the friction of cams. The solenoid has frequently attracted inventors, and some years ago it was applied to rock-drills, but was finally abandoned.

CHEMISTRY BUILDING, TEXAS SCHOOL OF MINES

Texas School of Mines

By COURTENAY DE KALB

The opening of the new plant of the Texas State School of Mines and Metallurgy at El Paso is an event of general interest. The School started under fine auspices, with a well-equipped teaching staff and an enthusiastic director in the person of S. H. Worrell. The first session was opened in the autumn of 1914 in the Military Institute buildings on the mesa above Fort Bliss, east of Mt. Franklin. It was an unfortunate site and the old structures were wholly inadequate for the purpose. An accident enabled the institution to take a fresh start under happier conditions. In October 1916 a fire swept the buildings out of existence, but in the meantime the School had demonstrated a reason for being, and the selection of El Paso as a proper site had received justification. A few public-spirited citizens, V. E. Ware, Ted Cooley, and A. S. Valdespino, agreed to deed a more suitable piece of ground for buildings and campus if the State Legislature would appropriate the funds for substantial permanent structures and equipment. The response was prompt, and construction began in the spring of 1917. The new campus lies on the edge of the residential district of El Paso on the south flank of a spur of Mt. Franklin, and only a mile from the works of the Consolidated Kansas City Smelting & Refining Co. It is a rugged piece of ground, but possesses many advantages. It is sheltered from the winds, is easily accessible from the city, and is so situated that the buildings present a striking appearance, while the outlook over the Rio Grande valley and the mountain-dotted

plains of Chihuahua is wide and inspiring. The architecture is a unique feature in America. On the initiative of Mr. Worrell the Bhutanesse style was selected as being particularly adapted to the surroundings. The special feature of the Bhutanesse type is that of a castellate building with massive walls that slope in graceful curves from the wide foundation to a roof conspicuous with its widely overhanging eaves. The lower story has few openings, beyond a stately entrance of oriental design. Being built partly into the mountain, the lower story thus serves mainly for storage, but the upper stories are abundantly lighted. The roofs, which have a sweep in keeping with the architectural styles characteristic of eastern Asia and Japan, are made of crushed red tile, mixed with an asphalt base that will not soften under the heat of summer. The broad eaves are painted pale green beneath, while the buildings are plastered in a rich cream color. Red, green, and yellow colors are repeated in the tiles, which are set into the medallions and are encircled by ornamental red brick forming the decoration between the upper row of windows. These are also outlined with ornamental red brick. This treatment gives a richness of color that brings the buildings into prominent relief against the brown slopes of the hills. The illustration shows the chemistry building before the contractors' rubbish had been completely cleared away. The main building is much larger and strongly suggests its Bhutanesse prototype in the mountains of northern India. An interesting detail of the construc-

tion is that the stone for the walls was quarried from the site of the buildings, and the gravel for the concrete came from the wash at the base of the hills. The cost was thereby reduced so that the entire group, consisting of a handsome main structure, a chemical laboratory, dormitory, and pumping plant, were erected for little more than would have been necessary for the larger building alone in a less favorable situation. In addition to the foregoing, a milling laboratory is being erected. Mill-tests will be made free of charge, and the advantage of this opportunity is extended to mine owners outside of the State as well as to those in Texas. It is required, however, that satisfactory evidence be presented to show that the sample lots represent orebodies of sufficient size to justify tests for determining a suitable process.

The separation of mining schools from the State universities is rather common in the West, and ordinarily it may be considered a misfortune, since it tends to weaken both institutions. Texas, however, is so enormous in size, and is so clearly divided into distinct eastern and western centres of population by a great central zone of elevated barren desert, that this division of the university brings with it some noteworthy benefits. It means that the State must maintain practically two adequately equipped universities, and the School of Mines accordingly will serve the needs of an institution of higher learning for the area tributary to El Paso. In this respect it will perform a larger function than that of training mining engineers. Nevertheless its courses will be essentially technical, and it will offer some special advantages in metallurgy, since the American Smelting & Refining Co. has liberally extended to the School the privileges for purposes of instruction of its local plant, which is the second largest custom-smelter in America. The faculty includes S. H. Worrel, the dean; John W. Kidd, professor of engineering; H. D. Pallister, professor of geology and mining; F. H. Seamon, in charge of chemistry and assaying; with numerous instructors in technical subjects, and professors of mathematics, economics, languages, and other branches. The examining board of the State legislature, headed by Oscar Davis, has recently reported favorably upon the new plant, which insures liberal appropriations for expansion.

FERTILIZERS are a more recent development of our industrial life than is generally realized. The first importation of natural guano from the islands off the coast of Peru was in 1840. Nitrate of soda began to be imported and used 10 years earlier. The potash deposits of Germany were worked for the first time in 1862, and the phosphate deposits of South Carolina were not exploited until 1868. The discovery of the Florida phosphate deposits was made as recently as 1888, and the great phosphate lands of Wyoming, Utah, and Idaho were unknown until 1906. The first experiments in converting insoluble phosphates into the soluble acid salt, by means of sulphuric acid, were made by Sir John Bennett Lawes in 1837 at the Rothamsted Estate, Harpenden, England, which he used as an experimental farm.

Potash From Feldspar

Two methods which show promise have been presented lately for producing potash from feldspar, and of these one is already in operation in Canada, on a limited scale. It is the invention of Allan Grauel, of Kitchener, Ontario, who worked it out originally to obtain potash for a powder plant. His process, which is patented, consists in heating in a blast-furnace, 110-ton charges of feldspar, coal, calcium chloride, and limestone. At a high temperature the potash distills over as potassium chloride into a condenser, where it meets a current of steam, which dissolves it. The salt crystallizes in a high state of purity. The recovery is 90% of the potash in the feldspar which contains from 8 to 14% of potassium oxide. Soda vapors come over with the potash, but it is claimed that these are separated in a satisfactory manner. In operating the blast-furnace the slag is run into molds and converted into sewer-pipe, tile, and paving-bricks, having a peculiar porcelain-like surface. A company has been formed that has the enterprise in hand. Another process is the invention of J. P. W. Frazer and E. Miller of Johns Hopkins University, Baltimore. In this, the feldspar is ground and mixed with a weak solution of caustic potash, evaporated to dryness, and heated to 200 to 300° C. The subsequent treatments are leaching and neutralizing with whatever mineral acid is desired for the potash salt. The remaining product is aluminum sulphate. A feldspar containing 10% of potash will yield $\frac{1}{4}$ ton of 80% chloride of potash to one ton of aluminum sulphate. An interesting feature is that no great heat is required and the process seems to proceed along economical lines. The alum cake is useful in clarifying water and in treating sewage, and there is always plenty of sewage.

THE MALAY PENINSULA produces more than half the world's supply of tin in the form of concentrates, which are smelted chiefly at the extensive works at Singapore and Penang. These huge smelting plants, with a capacity of more than 7000 tons of tin per month, receive supplies of ore from Siam, the neighboring Dutch islands, and other tin-producing countries, so that the output is considerably in excess of the tin actually mined in the Malay States. Added to this is the tin from many small smelting plants in the Straits Settlements and the Malay peninsula, which is brought to Singapore for export. By reason of these facts the Straits Settlements takes rank as the world's largest exporter of tin, Singapore holding first place. The tin produced in the Federated Malay States yielded in 1916, on the metallic basis of a 70% concentrate, 43,870 tons, of a value of \$36,630,721, as against 46,766 tons in 1915. In addition, 4383 tons of tin was produced in the non-federated Malay States, making a total of 48,253 tons for the entire Malay peninsula. The decreased production is attributed mainly to labor shortage, due to the increasing attractiveness of the rubber industry, which has assumed large proportions.

Output of Washington Mines

The value of the gold, silver, copper, lead, and zinc mined in Washington in 1917, according to the estimate of C. N. Gerry, of the U. S. Geological Survey, was about \$2,238,000, an increase of 9% over the value in 1916. There was a decrease in the production of gold, silver, copper, and zinc, but an increase in that of lead. This increase and the higher prices of metals gave the output a value slightly above that of 1916, which was \$2,048,350. Strikes at the Canadian smelters at different times during the year caused a curtailment of shipments from Washington, especially from the Republic and Chewelah districts. The plant at Trail, B. C., which owns and operates several mines at Republic, was idle in December. The Northport Smelting & Refining Co., however, operated a lead plant throughout the year and received much of the silicious ore from Republic.

The mine production of gold decreased from \$577,655 in 1916 to about \$486,000 in 1917. The Boundary Red Mountain mine, in Whatcom county, was among the principal gold-producers. The production of the Republic district was seriously affected not only by strikes, which closed the mines, but by labor troubles at the smelters. The output of this district, which was 45,313 tons in 1916, was reduced to about 36,000 tons. The Lone Pine-Surprise-Pearl property was, as formerly, the main shipper. The Knob Hill was next, and the Tom Thumb, Quilp, Hope, and San Poil were large contributors. A new shaft was sunk at the Knob Hill mine, and further depth was gained at the Last Chance and the Lone Pine properties.

The mine output of silver decreased to about 257,000 oz., or over 23%. The value of the output was about \$208,000. Most of this silver came from copper ore mined in the Chewelah district, and a large part of the remainder from silicious ores mined in the Republic district. The ore output of both districts was less than in 1916.

The copper output decreased to about 2,000,000 lb., valued at \$607,000. The output of ore and concentrate would have been much greater if the smelters had been able to receive it. At the United Copper mine, in the Chewelah district, sinking was in progress below the 1000-ft. level. Several dividends were paid during the year. The shipments of crude ore and concentrate averaged nearly 600 tons per month. The Sunset mine made shipments of copper ore during the first half of the year, and some was shipped from the Loon Lake property, in Stevens county. In May a shortage of coke prevented further shipments from the smelter at Trail. Several shipments of copper ore were made from the High Grade property, at Turk, in south-western Stevens county.

The lead output increased to over 9,000,000 lb., valued at about \$824,000, representing an increase of nearly 4,000,000 lb. in quantity and \$450,000 in value. The product came largely from carbonate and sulphide ores

mined at the Electric Point property, in the Northport district, Stevens county, which was profitably operated during the year. Other properties in the district having first-class or milling lead ore are the Gladstone, Mineral Belt, Providence, and Iroquois. A few shipments were also made from the Bonanza mine, in the Bossburg district, Stevens county.

There was a marked decrease in the zinc output, because the Great Western and Last Chance properties ceased operations in 1916. The ore shipped from the Lead Zinc property at Metline Falls, however, produced more than a million pounds of spelter. Part of

PART OF IDAHO AND WASHINGTON

the ore was shipped to Eastern zinc smelters and part was treated in the electrolytic plant at Trail, B. C.

The dividends paid by Washington mines for 11 months of 1917 amounted to \$213,163. The mines making payments were the Electric Point, United Copper, Knob Hill, and Loon Lake mines.

COPPER production in Alaska in 1917 was about 88,200,000 lb., valued at about \$24,000,000. This is less than the production in 1916, which was 119,600,000 lb., valued at \$29,484,000, but is greater than the production of any other year. The reduction in output was due largely to labor troubles at the Kennecott Bonanza mine. During the year 17 copper mines were operated, compared with 18 in 1916, 8 being in the Ketchikan district, 6 in the Prince William Sound district, and 3 in the Chitina district. The enormous output of the Kennecott Bonanza mine, in the Chitina district in 1917, as in previous years, overshadowed that from all others.

SULPHUR mixed with organic refuse, raw phosphate rock, and soil, and kept moist for several weeks, results in converting the phosphate mainly to the soluble acid compound.

Idaho Mine Output in 1917

The value of the gold, silver, copper, lead, and zinc mined in Idaho, according to the statement of C. N. Gerry, of the U. S. Geological Survey, was about \$54,000,000, an increase of more than \$5,000,000 over the value in 1916. There were decreases in all the five metals except lead, in which there was a slight increase. Idaho was freer from labor troubles than the neighboring States, particularly Montana and Washington. The average prices of silver, copper, and lead were unusually good, and every effort was made to ship larger quantities of ore, particularly lead ore. The new lead smelter of the Bunker Hill & Sullivan, near Kellogg, began operations in July, and the lead plant at Northport, Washington, was active during the entire year, treating principally Idaho silver-lead ores. The output of crude ore and concentrate, both lead and zinc, increased from 527,266 tons in 1916 to about 527,000 tons in 1917.

There was a decrease in the gold output from \$1,115,810 in 1916 to about \$715,000 in 1917, due principally to the fact that the large dredge at Idaho City, Boise county, was idle. Shipments of gold bullion were made from the Marshall Lake district of Idaho county, where the Sherman & Corporal property has become a large gold-producer. The lead ore produced contains a small amount of gold, and the copper ore, especially that of the Alder Creek district, in Custer county, and the Richmond mine, in Shoshone county, contains considerable gold. A dredge that had been moved from Alaska to Prichard creek, near Murray, in Shoshone county, was ready for operation in December.

The production of silver was about 11,773,000 oz., slightly less than that in 1916, when the State produced 12,300,873 oz. The price, however, was so much better that the value of the output increased from \$8,093,974 to about \$9,536,000. The Coeur d'Alene region contributed most of the silver, and the largest producers were the Hercules, Bunker Hill & Sullivan, Morning, Hecla, Caledonia, Tamarack & Custer, Greenhill-Cleveland, Gold Hunter, Stewart, Consolidated Interstate Callahan, and Last Chance. In Boundary county, considerable silver is contained in concentrate shipped from the Idaho Continental property. In Lemhi county also silver is produced from lead ore. Increased output was made by the Morning, Hecla, and Bunker Hill properties.

The mine output of copper decreased from 8,478,281 lb. in 1916 to about 6,753,000 lb. in 1917. The value decreased from \$2,085,657 to about \$1,971,000. The properties at Mackay, in Custer county, and principally the mine of the Empire Copper Co., contributed most of the copper output. Shipments of copper ore were made from the Richmond mine, where the new tramway to Adair was operated. The Caledonia mine at Wardner produces ore containing copper as well as silver and lead. Toward the end of the year the plant of the National Copper Co. was again operated and made shipments of

concentrate in November and December. Other shipments were also made from the Horst Powell property, north of Kellogg.

The output of lead increased from 375,081,781 lb. in 1916 to about 383,000,000 lb. in 1917, and the value increased from \$25,883,643 to about \$34,595,000. The principal producers in the Coeur d'Alene region were the Bunker Hill & Sullivan, Hercules, the Federal properties (especially the Morning mine), the Hecla, Greenhill-Cleveland, Caledonia, Success, Gold Hunter, and Consolidated Interstate Callahan. The Jack Waite property became a shipper of lead ore, and the Hypotheek increased its lead output. Having acquired the Frisco mill, the Tamarack & Custer Consolidated made shipments of lead concentrate in the last half of the year. In Lemhi county, the Pittsburgh-Idaho, Latest Out, and Gilmore made shipments of lead ore; in Boundary county, the Idaho Continental; at Arco, the Wilbert Mining Co.; and near Mackay, the Copper Queen and Homestake. Ore production in Lemhi county was less than in 1916.

As the price of zinc decreased considerably toward the end of the year, the average was only about 9 cents per pound. The State output decreased from \$6,505,219 lb. in 1916 to about 80,000,000 lb. of recoverable zinc in 1917. The value was approximately \$7,336,000. The output of the main producer, the Consolidated Interstate Callahan, decreased about 20%. This mine averaged over 5000 tons of ore and concentrate per month, part of which was a lead product. Shipments of zinc ore or concentrate were also made from the Morning, Success, Rex, Highland Surprise, Constitution, Greenhill-Cleveland, Frisco, Black Hawk, Marsh, Douglas, Ray-Jefferson, and Nabob. Most of the zinc came from Shoshone county, but the North Star mine, near Hailey, in Blaine county, belonging to the Federal company, became a producer of zinc concentrate during the year. A great part of the zinc product was sent to the electrolytic plant at Great Falls, Montana, and part of the ore, such as that from the Douglas mine, was concentrated after being shipped.

The dividends from Idaho mining for 11 months amounted to nearly \$6,000,000. The principal contributors were the Hecla, Bunker Hill & Sullivan, Caledonia, Hercules, Consolidated Interstate Callahan, Pittsburgh-Idaho, Wilbert, Empire Copper, Big Creek Leasing Company, Douglas, Richmond, Black Hawk Leasing Company, and Tamarack & Custer.

HOT SPRINGS are numerous in Alaska. The cause is traced mainly to expiring volcanic activity. A recent bulletin (Water Supply Paper 418) issued by the U. S. Geological Survey, describes the hot springs of Alaska, and states that they do not seem to be related to great structural features, but are associated with intrusive rocks. Many of those in the Yukon basin are related to granitic masses intruded into the schists, and their chemical analyses show that part of the solid carried in solution was derived from minerals in the schist.

REVIEW OF MINING

PHOENIX, ARIZONA

A REVIEW OF MINING IN 1917 AND OUTLOOK FOR 1918

The Arizona copper output for 1917 when all figures are in will show a gain of 25,000,000 to 50,000,000 lb. over 1916. But for the I. W. W.-promoted strikes, beginning with the attack on New Cornelia that was intended to prevent the property from coming into production in 1917 and did delay its entry for a matter of two months, Arizona would have made over 300,000,000 lb. more of copper in 1917 than in 1916. The increase over 1916, in spite of strikes, is to be credited to greater and more efficient mechanical equipment and to large resources in high-grade ores in the vein mines that had been made ready for extraction in advance of the breaking of trouble. The present year's output starts under the handicap of a great reduction in high-grade reserves and a metal price that will not permit the mining of the low-grade ores. The checking of output, while more ore is opened than can be profitably mined at 23½¢, with some closing-down of mines by small producers, mainly shippers of custom ore, is to be anticipated; in fact, has begun. Decrease in working forces necessarily attends, and with the curtailment and suspension of work on developing properties, which is in progress because of high costs, the difficulty in financing under existing general conditions, and the unpromising price-outlook for copper metal, there is being considerable disorganization of working forces brought about, together with an increase in the surplus of labor that has prevailed in the copper districts for some time. That the price of copper was not put above 23½¢ was a disappointment in Arizona, particularly to the small producers, many of whom had been maintaining shipments at a loss in the belief that price would be advanced and that they would be out less by accepting a small loss in the interim than closing-down their properties and assuming the extra expense of re-opening when the price did advance. Advance in copper price to 26¢, with assurance that such price would not be decreased, would enable at least 10,000,000 lb. more copper per month to be produced from Arizona than can possibly be made on a 23½¢ market. No one familiar with mining can possibly figure that decreased price for metal can bring about higher output. The lower the price the higher the grade of ore that must be mined, and every miner knows that the high grade is a limited quantity, either present or possible of attainment, in any mine, and that in the development of high-grade it is impossible to use more than a limited number of men. In Arizona labor conditions are in a fairly settled state, supplies are coming through fairly well, and other conditions are favorable to a year of increased metal output, attended by considerable additions to ore-reserves through the opening of new properties; the metal price represents the only retarding feature.

COCUPE COUNTY. The Denn-Arizona has placed pumps in the 1430-ft. level ready to clear water from the 1600-ft. level as soon as some small supplies are received. Water is now a little below the 1500-ft. level. Calumet & Arizona is driving on the 1600-ft. to the Denn line, where promising ore was recently found on the 1400-ft. level of that property. The December production of C. & A. is 5,816,000 lb., compared with previous 1917 high production in May of 5,688,000. The Copper Queen

December production from Warren district ores was 9,000,000 lb. copper, compared with previous high in May of 8,600,000 lb. on the planned 8,000,000 lb. monthly production during 1917. Shattuck alone in the Warren district showed decrease in December, with an output of 626,612 lb. for the month. The decline in part was due to the preparation of lead-silver ore-bodies for the extraction of 400 tons per day for the mill, which is being erected rapidly and will be ready for operation in May, and to the larger forces directed to development in high-grade copper-zones. More development of the higher grade will be necessary on the part of nearly all the vein-copper producers in the State with copper remaining at 23½¢. The price will not permit mining of the low-grade ore. Owing to the diverting of labor to higher-grade development and the limited working room, decline in the State's monthly copper production is anticipated until re-adjustment is obtained through work in succeeding months and the losses are overcome. This will be attended by the closing down of small shipping properties in various districts of the State, representing probably 1,001,000 lb. copper per month, which have been hanging on, hoping for an increase in price.

PIMA COUNTY. New Cornelia made 2,260,000 lb. of copper from cathodes, 500,000 lb. from shipping ore, and 1,090,000 lb. from cement copper in December, a total of 3,850,000 lb. for the month. Four million pounds per month is indicated as readily within the capacity of Cornelia in succeeding months. Plans for the erection of a smelter on this property are being matured and specifications are under way. There is no intention, however, of erecting a smelter this year, unless there should be a marked decline in the cost of materials. Ajo Consolidated underground development by Cornelia is well under way and will increase steadily. Ores in this property as well as in the steam-shovel pit of Cornelia are averaging higher in metal content than advance exploration figures indicated.

YAVAPAI COUNTY. Dundee has closed down pending completion of arrangement by which it will use the new Verde Extension traffic tunnel to gain entrance and make a raise from around the 900-ft. level to the shaft it has been sinking. Costs of pumping and hoisting will be dispensed with under this plan. Jerome Victor Extension is expecting to recover the 1200-ft. level from the water and resume development there at an early date. The 1200-ft. has been opened slightly; the showing there is promising for the small extent that it has been possible to follow it. Water increases, pump troubles, and machinery break-downs have interlarded at several times. The Verde Extension new blower has greatly improved conditions underground. The fire area has about been disposed of. Progress with the smelter of this company is going on well. The Verde Combination ore find on the 600-ft. is near the Gadsden line and is encouraging, although more depth is considered requisite to establish individual value for the strike. The Calumet Jerome is in the same situation, requiring more depth to enable deductions of value. The Del Monte closing-down is apparently for an indefinite period, although additional equipment was received and in course of installation when the closing order came, while a year's stock of general supplies is on hand at the camp and there is an abundant sum of money in the treasury for another year's work. Labor is

plentiful in the district, a surplus having been on hand for some time. The demand for an increase of \$1 per day both above and below ground will probably be adjusted by administrator Meyers. The I. W. W. disturbing elements are held to be responsible for the demands. Costs of living in the district are asserted at this time to be no higher than when the present wage scale was agreed upon in June. The administrator is now investigating the costs of living, upon alleged increase in which the demand for higher pay is based. The present wage is \$5.15 per day.

GILA COUNTY. The development of high-grade copper ore on the 1000-ft. level at Iron Cap indicates an exceptionally important strike for the Globe district and lends much encouragement to the exploration that Old Dominion, Commercial, and Superior Boston have been carrying on at depth, with attendance of good results. The outlook is also improved for New Dominion and several other developing properties. Iron Cap ore is in bornite and on the 1000-ft. level averages 12½% copper with about 10 oz. silver. On the 800-ft. level the ore has an average width of 8 ft. and on the 900-ft. of 12 ft. and carries 10% copper. Sinking from the 1000 to 1100-ft. has been started. Arizona Commercial is opening new stopes between the 1500 and 1400-ft. levels and pushing development vigorously with good results on the 800, 1000, 1200, and 1500-ft. levels. The water area has been lowered between the 1200 and 1500-ft. levels. Porphry Copper Co. is to black out ore, preparations being under way to cut stations at 530 and 630 ft. in the shaft and start driving.

TONOPAH, NEVADA

TONOPAH MINING.—TONOPAH BELMONT.—TONOPAH EXTENSION.
—WEST END CON.—TONOPAH HALIFAX.

The Tonopah Mining Co. shipped 35 bars of bullion valued at \$67,500, representing the final clean-up from the plant at Millers for December. A conservative estimate of the time required to treat the old dumps, based on 300 tons per day, is one year. Last week 2400 tons was milled averaging \$7.50 per ton. During the past week 57 ft. of development has been done in the Silver Top and 53 ft. in the Sandgrass. Raise No. 386 at the Silver Top disclosed no ore in the hanging wall of the Valley View vein. On the 1140-ft. level of the Sandgrass the raise on the Upper Sandgrass vein holed through and stoping has been started. Last week's production was 3650 tons.—The Tonopah Belmont Development Co. shipped 57 bars of bullion valued at \$102,517 and 43 tons of concentrate valued at \$19,350. On the 700-ft. level east drift No. 721 on the Shoe-string vein shows a 2½-ft. face of medium-grade ore. Raise No. 8 on the same vein shows a 2-ft. face of good ore. Stoping has been commenced from raise No. 8. On the 800-ft. level a raise from the Occidental vein cut the faulted segment of the South vein, showing 4 ft. of good ore. On the 900-ft. level north-west cross-cut No. 9025 cut a branch of the rhyolite vein; exposing good ore. The production last week was 2269 tons.—The Tonopah Extension Mining Co. recently cut the extension of the O. K. vein on the 1680-ft. level of the Victor. The width of the vein has not yet been determined, but the dip flattened as did the Merger vein that was cut a short time ago. The 1600 west drift of the Victor advanced 31 ft. on a 4-ft. face of ore. On the 1540-ft. level winze No. 1501 continues in ore. At the No. 1 shaft on the 1260-ft. level raise No. 469 is on a 3-ft. face of ore. At the No. 2 shaft 87 ft. of development has been done and 153 ft. at the Victor. The past week's production was 2380 tons.—At the Ohio shaft of the West End Consolidated Mining Co., drift No. 535 continues in good ore. Winze No. 534 cut a fault, and the vein has been picked up on the other side. In raising out of No. 528 raise some exceptionally high-grade ore has been found. The 814 raise still continues in quartz; the hanging wall of the vein has not been reached. The output last week was 1019 tons.—

At the Halifax Tonopah Mining Co. a small stringer of quartz was found in the cross-cut No. 1018. The stringer shows good ore and driving has been started on it. The output last week was 56 tons.—The Jim Butler produced 412 tons, the Mac-Namara Mining Co. 416 tons, the Montana 109 tons, the Rescue 66 tons, and Midway 46 tons, making the total production at Tonopah 10,423 tons with a gross value of \$182,403.

MONTERREY, MEXICO

AMERICAN MINES BEING WORKED.—LA COMPANIA METALURGICA

Comparatively few American mining men have as yet returned to their properties in Mexico, despite the improved internal conditions in some parts of the country. It is stated that in the Guanajuato district little effort is being made to resume operation of foreign-owned mines, although there are some such properties which have kept up their output during nearly all of the protracted revolutionary period. In the mining districts, situated more adjacent to Monterrey, there is a considerable renewal of development activities. In the Cerralvo and the Concepcion del Oro districts American-owned properties are again being worked to the fullest extent that the hindrance in getting in supplies and shipping out ores will allow. It is noteworthy that the mines that are owned by Germans are about the only ones that are doing a large production at this time. This is true as to the Mapimi and Bermejillo districts as well as in several of the districts of Chihuahua. A syndicate of Germans has recently acquired valuable mineral holdings in the Pachuca, El Oro, and Guanajuato districts, according to advices received here. It is stated that these mines were forfeited from American owners by the Mexican government for alleged failure to pay taxes and other assessments.—Arrangements are being made for the re-opening of the large smelter of La Compania Metalurgica at San Luis Potosi. This is an American concern. J. D. Wilson of New York, assistant manager for the company, is now in San Luis Potosi looking after matters connected with the plant's early resumption of operations. It is stated that a large supply of coke has been received and that ample ores are on hand and in prospect to keep the smelter going. With improved transportation facilities it is expected that there will be no cessation of the smelter's run when it is once again started. Revolutionary conditions in the State of San Luis Potosi are said to be much improved over what they were only a few weeks ago. Bandits continue to menace the division of the National Railways of Mexico that runs between San Luis Potosi and the port of Tampico.—In the States of Coahuila and Tamaulipas two or three new independent revolutions are now in progress, but none of them has as yet gained much headway. Several smaller towns have been raided recently and skirmishes between the different revolutionary bands and Carranza soldiers are of almost daily occurrence. The town of Cuatro Ciénegas, State of Coahuila, the former home of President Venustiano Carranza, and where the distillery that he operated is situated, has been in the hands of revolutionists for several weeks.—Several of the larger mines in the more remote mountain districts of the State of Durango are being operated, but on account of the lack of transportation facilities the ore production is not being shipped. The division of the National Railways of Mexico, between Torreon and Durango, has been out of commission, except at brief and far removed intervals, for more than eight years. The smelter of the American Smelting & Refining Co. at Asarco is on that line. It was reported recently that this plant was about to be again placed in regular operation, but there has been no verification of this statement received here. It is deemed improbable that revolutionary and banditry conditions would at this time permit the re-opening of the plant unless a large and constant guard of troops were maintained to afford it protection.

THE MINING SUMMARY

ALASKA

(Special Correspondence.)—The Union Power Co. has been incorporated under the laws of Alaska to construct a hydro-electric plant to furnish power to all of the operating mines in the Willow Creek district. The incorporators are: J. F. Wood, Conrad C. Hage, and M. M. Henley. It is proposed to install two 200-kw. generators in the spring and build 12 miles of transmission line to supply the mine, and the equipment will be increased as necessity develops. A site for the plant has been chosen near Mile 28 on the Willow Creek road.

Anchorage, December 19.

(Special Correspondence.)—The first copper-concentration mill to be installed in the Ketchikan district has been in operation for three months at the Salt Chuck mine, Kasaan bay. This plant has a capacity of 60 tons per day and is quite simple, consisting of a Blake crusher, ball-mill, drag classifier, and flotation rougher and cleaner cells. A Deister table was included but was found to be unnecessary. The power is furnished by a 150-hp. hydraulic plant which also supplies some power for mining operations. A gas or steam plant will likely have to be added to prevent the necessity of closing down during dry spells. The ore contains bornite and chalcopryite with epidote and gabbro in the gangue. An extraction of over 90% is claimed. The property is owned by J. E. Chilberg, of Seattle. F. Chapman is manager and G. H. Bannerman, superintendent. The preliminary examination and suggestions for equipment were made by W. L. Polson in April 1915.—A small plant for treating a complex copper-zinc-lead ore is under construction by the J. L. Harper Mining Syndicate at Complex, North Arm, Moria sound. The Rush Brown, Sulzer, and It mines are shipping steadily and supplying considerable ore to the smelters. The Granby M. & S. Co. is preparing to reopen the Mamie mine at Hadley. This company is also doing considerable development work at Rich Hill, and several other places in this district.—Exploration underground is being maintained in the large disseminated mineral zone on the Apex group at McLeans Arm.—The Ketchikan district should be an attractive field for mining men on account of the large amount of easily accessible property containing ores previously overlooked as being too low grade for shipping to the smelters.

Ketchikan, January 10.

The Marble gold mine in the Willow Creek district has been sold to Butte people for \$500,000.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—A disastrous explosion occurred at Bisbee on the afternoon of January 9 when over 3000 lb. of blasting-powder was prematurely exploded on Sacramento hill where the Copper Queen Co. is carrying on extensive steam-shovel operations. Two men were killed, two fatally injured, and eight others seriously hurt. One hole had been loaded ready for firing and the powder-men were putting in the primer and electrical connections in another when the explosion took place, the cause of which is not known. The two men killed were Sidney Drakefield, an engineer in the employ

of the company, and Modesto Vastido, a laborer. The two men who are said to be fatally injured were Carlos Calderon and Juan Nunez. The men seriously injured are Nat. Anderson and J. D. McBride, powder experts, the remainder being Mexican laborers.

Douglas, January 12.

MOHAVE COUNTY

(Special Correspondence.)—The shaft of the Record lode has reached a depth of 350 ft. and development by cross-cutting and driving is to be carried on as soon as a station is cut.—The force of men at the United Oatman has been increased. The adit that is being driven in the contact vein is in nearly 800 ft. The west cross-cut has been advanced about 250 ft.—The ore opened up in the West drift of the Gold Road Bonanza is the full width of the face of the drift and is all commercial ore.—Shaft-sinking at the Gold Ore has been completed, and a sump and station are being cut. An electric pumping plant is being placed on the seventh level.

Kingman, January 14.

YAVAPAI COUNTY

(Special Correspondence.)—The adit of the Fortuna Consolidated Co. is now in over 800 ft. and, according to calculation, should cut the main east and west vein any day. The adit is being driven on a north and south vein to cut an east and west vein series. For the last 100 ft. the adit has been in ore of varying grade. A portion of the ore is rich and it has been officially confirmed that shipments can now be made, which should net the company at least \$100 per ton. The principal mineral of the ore is gray copper.

Prescott, January 18.

CALIFORNIA

NEVADA COUNTY

(Special Correspondence.)—By means of a concrete dam and long flume the Golden Center Co. has diverted the flow of considerable water from surface streams to Rhode Island ravine, which empties into Wolf creek. During heavy storms numerous shallow shafts and old surface workings filled with water that afterward seeped into the mine, imposing a heavy strain on the pumps. With this water diverted, the management expects to unwater the lower workings without further difficulty. The mill is running steadily on good ore from the western workings of the mine. The shaft is being sunk to 2000 ft.—The shaft of the California mine, in the Deadman Flat section, has been sunk to a depth of 800 ft., and cross-cutting begun to explore promising ground. This is the deepest point to which developments have been carried in the district, but thus far results have been rather disappointing. The California is controlled by King C. Gillett of Los Angeles.—Eastern capital has taken a bond on the Mayflower mine, owned by W. H. Martin of Nevada City. It is reported that a fund of \$150,000 has been provided for comprehensive developments and the purchase of new equipment. The Mayflower was formerly a rich gold-producer but has attracted little attention in late years.—Placer mining at You Bet is again active and the old camp is showing more life than for many years. White miners are largely employed and the Board of

Supervisors has ordered the establishment of a voting precinct.

Grass Valley, January 21.

SHASTA COUNTY

(Special Correspondence.)—The Afterthought mine and oil-flotation plant at Ingot will be started up before the end of the month with a full force of men, according to George L. Porter, president of the company, who has just returned from St. Louis. The works were shut-down on November 30 owing to a defect in the oil-flotation process and the shortage of cars. Both these troubles have been remedied. The ore is subjected to two flotations; the first removes the sulphide from the gangue; this concentrate is roasted and again floated when the zinc is separated from the copper. The separation is said to be fairly sharp. The company will erect 20 cottages for the convenience of its employees. It spent \$650,000 last season in building its oil-flotation plant, paying off debts, and making other improvements at the mine. J. T. Milligan, a mining engineer of Colorado Springs, and J. M. McClave, a metallurgist, have arrived at Ingot to assist the general manager, J. T. Robertson.

Redding, January 14.

SISKIYOU COUNTY

(Special Correspondence.)—A. W. Boslough and Louis G. Glieve of Ashland, Oregon, who have a three-year lease from John R. Clute on the S. B. Bar placer ground of 40 acres, on the Klamath river one mile below Gottville, are assembling machinery to sink a two-compartment shaft. This property in early days, when known as the old Manzanita Bar mine, produced \$200,000 in gold.—T. K. Anderson of the Pilot Knob group of quartz mines on Empire creek is operating on a large body of ore.—Fifty men are employed in the Grey Eagle Copper mine near Happy Camp, and arrangements have been made to continue operations during the winter. In the coming season the management is planning to build a railroad to some point on the Southern Pacific or to tidewater, and a flotation plant is also under consideration.—The Blue Ledge copper mines produced 800,000 lb. of copper during the past year. The county produced 15,000 oz. silver.—In addition to the mill erected last spring, a new cannon-ball mill with a capacity of fifty tons has been erected on the Rancherie mine near Hornbrook. This property is a cement-gravel mine under sandstone rock and was formerly known as the Black Jack mine.—Joseph Freshour is operating his placer drift mine on Lum Grey creek near Gottville. The mine is equipped with a steam-hoist and a water-wheel pump.

Hornbrook, January 15.

TUOLUMNE COUNTY

(Special Correspondence.)—Through the Pacific Coast Mines Corporation, Boston capitalists have taken over the App, Dutch, and Sweeney mines, at Quartz. The corporation has been authorized to issue 1,499,495 shares of stock, besides bonds in the sum of \$300,000, to the owners, to complete the purchase price. It is stated that the properties will be worked on an extensive scale, and that during the coming summer a mill with a daily capacity of 700 to 800 tons will be erected. Documents recorded in this county during the past few days show that the Springfield Tunnel & Development Co. has obtained the right to drive an adit not to exceed 8 by 8 ft. through land near Springfield owned by John Wight; also the right to construct roads across said land, and to erect any buildings necessary upon the property. In return the company grants to Mr. Wight the surface right to a certain tract of land comprising 120 acres; to pay to him 25% of all gold extracted from his ground, and the use of the proposed adit to open his own ground, provided he does not disturb or delay the company's operations in so doing. It is said that one of

the richest gravel deposits known in the company's holdings, on the west side, can be reached by the middle of the present year by driving an adit through the Wight land. The long adit from the canyon of the Stanislaus river will not be abandoned, but will be completed at a later time to open certain other ancient channels in the property that cannot be advantageously explored and worked through the proposed adit on the west. It is announced that operations will be resumed at once and vigorously pushed.—The Confidence mine shaft is being deepened another 100 ft. from the 1100-ft. level, a contract for this work having been taken by C. Sullivan.—Ore speckled with gold is being taken out of the Fifth Ward mine, near Arastraville, recently bonded by Robert Marshall of Sonora to John W. Bates. The vein is from 4 to 7 in. wide. The rich ore was uncovered in a winze near the face of a 208-ft. adit.—A 5-stamp mill has been purchased for the mine on the Hales & Symons property, just south of Sonora, which

TUOLUMNE COUNTY, CALIFORNIA

is being developed under bond by C. R. Rives and associates. A head-frame will also be erected and the property worked on a larger scale than in the past. Shafts have been sunk in the large vein in several places and in every instance ore ranging from good to high-grade has been found.

Sonora, January 12.

COLORADO

DENVER COUNTY

(Special Correspondence.)—The plant of the Chemical Products Co., at Denver, was visited by a disastrous fire of incendiary origin on January 14. The loss is between \$50,000 and \$75,000. The company has been producing vanadium on sublet contracts for the British government. The plant will be re-built immediately to discharge these and other contracts.

Denver, January 15.

TELLER COUNTY

(Special Correspondence.)—The important development of last week has been the finding of pay-ore in the breast of the Roosevelt tunnel, at a depth of 2100 ft. in Rose Nicol territory, 300 ft. east of the main shaft and near the east line of the Portland estate. The vein, pronounced the Hidden Treasure vein of the Portland system, sampled \$3.60 to \$12.80 per ton; it is confidently expected an ore-shoot will be opened.—The Rose Nicol is under lease for a six-year term to the Camp Bird Mining, Leasing & Power Co. During the past week the company finished sinking on the Rose Nicol on the western slope of Battle mountain, having reached a depth of 981 ft., which corresponds to the 1000-ft. level of the Portland Gold Mining Co. No. 2 shaft, from where a drift has been run on ore into the Rose Nicol ground, and to 1200 ft. in the Trail

mine of the United Gold Mines Co. to the west. Shipments will shortly be moving from the Rose Nicol.—The annual stockholders meeting of the Golden Cycle Mining & Reduction Co., a West Virginia corporation, will be held at the office of the company at Colorado Springs on Thursday, January 31, for the election of a board of seven directors.—The annual stockholders meeting of the Portland Gold Mining Co. for the election of directors has been called for February 18, at Cheyenne, Wyoming. Stockholders of the company will be paid a 3c. dividend, \$90,000, on January 20; with this payment they will have received \$11,047,080 in dividends.—The annual meeting of the Vindicator Consolidated Gold Mining Co. will be held at Denver, on February 14. At the last meeting, the directors determined to pass the January quarterly dividend. The Vindicator company has paid \$3,713,500 in dividends.—A new ore-shoot on the C. K. & N. vein has been opened up by lessees of the El Paso Consolidated Gold Mining Co., between the 900 and 800-ft. levels of the No. 1 shaft on the western slope of Beacon hill. The vein, which is 3 ft. wide, will ship at better than one ounce gold per ton.—Annual meetings of the Mary McKinney Mining Co., Elkton Consolidated Mining & Milling Co., and Isabella Mines Co. will be held during the month of February.

Cripple Creek, January 19.

MONTANA LEWIS AND CLARK COUNTY

(Special Correspondence.)—The Helena Mining Bureau held its annual meeting the middle of January and elected a new board of directors and officers. The report of the secretary-treasurer showed that \$27,000 worth of ore was paid by the smelter and that the main shaft is down 300 ft. vertically. The stockholders appeared well pleased with the showing. An additional 100 ft. is to be added to the depth of the shafts in the near future. The hoisting apparatus is ample and a two-ton skip is used in raising ore and waste to the surface. The mine is in Grass Valley district, about four miles west of Helena.—The Marysville Gold Syndicate, which has been developing property in Marysville district for the past year, has closed down. The syndicate was composed mostly of Duluth people. The sum of \$150,000 was expended in mining and in securing options on mining ground. Final action depended on reports by mining engineers that were insisted on by Eastern capitalists. These engineers visited the property lately and after an examination extending over 17 hours they reported adversely. As to the future of the syndicate property nothing is known at this time.—The Barnes-King Mining Co. is operating very successfully on the Shannon mine, which adjoins the syndicate property on the west. The Shannon shaft is down 500 ft. and an additional 150 ft. is being added. When the shaft has been sunk to the 650-ft. level drifts are to be run east and west. The 500-ft. level disclosed rich gold ore.—Denver people have taken over the Mountain States mining property at the head of Warm Springs creek, Jefferson county, and are unwatering the main shaft, which is down 150 ft. The ore is silver-lead; the property was worked 15 years ago.—The Liverpool mine in Lump gulch, Jefferson county, has been purchased at a tax sale for \$2500 by a Helena syndicate. It is developed by a 750-ft. shaft. The ore is silver-bearing and high-grade. The property was owned by the Pittsburgh-Montana company.—The Amalgamated Silver Mines Co. is deepening an old shaft on Free Coinage ground in Lump gulch. The shaft, which was down 180 ft. is being sunk to the 250-ft. level. The ore shipped from the workings averaged 115 oz. silver per ton. The company controls 35 claims in the camp, all contiguous.

Helena, January 16.

SILVER BOW COUNTY

(Special Correspondence.)—The High Ore and the St.

Lawrence, in the Butte district, both of which have been closed for repairs for a long time, resumed operations on January 14. The former will employ 500 and the latter 400 men. Both will start hoisting ore immediately, and should increase the daily production at least 1700 tons. The starting of these two mines means that practically all of the large mines in the district are operating to capacity.—The production of the East Butte for December amounted to 2,500,000 lb. of copper as compared with 2,033,000 lb. in November, an increase of 467,000 lb. Those figures make a record month for the company, the previous highest having been September 1917 with a production of 2,203,300 lb. This record is aided to some extent by the treatment by this company of the Davis-Baly Copper Co. ore, which has been of good grade, the first class assaying from 10 to 16% copper, while the second class usually ran from 3 to 5%.

Montana's output of minerals for the past year shows a de-

BUTTE MINING DISTRICT

crease in value of \$20,000,000 as compared with the production of 1916. This was caused to a great extent by the idle period of over two months when the mines in the Butte district were closed on account of labor trouble. Metal prices were high, with the exception of zinc, but the mining profits were not unusual, because of the high cost of material and of labor. Gold, copper, silver, and zinc showed a decrease in the output value and lead an increase.

Butte, January 16.

NEVADA

HUMBOLDT COUNTY

(Special Correspondence.)—The Rochester United, which joins the Merger, has recently found a shipping grade of ore, but not in sufficient quantities as yet. In a raise from the drift on the Silver King adit-level 15 in. of ore runs 20 oz. in silver and \$8 in gold per ton. The drift also is going ahead and, while for a time the vein-filling was badly broken up, it is now apparently entering another ore-shoot. The vein-filling is of good-looking quartz from which encouraging assays have been received.

Rochester, January 17.

MINERAL COUNTY

(Special Correspondence.)—The north-west drift on the

1000-ft. level of the Calavada mine at Luning is advancing four feet per day between monzonite and dacite along an oxidized vein carrying bunches of high-grade oxidized copper ore. It will connect with the new shaft on the Chief claim, which is designed for ventilation of the main workings and to develop an ore-shoot that comes to the surface near by. From this ore-shoot 100 tons of 12% copper ore was extracted near the surface. The winze that is being sunk from the 1000-ft. level near the main shaft is down to the 1135-ft. point.—The Luning-Idaho mine is extracting some unusually handsome specimens, running high in copper, from Stockham adit No. 2, where work is now being concentrated.

The R. B. Todd mine will explore a 6-ft. vein at the top of Todd mountain that runs \$12 per ton in gold and silver by a short adit.—A cross-cut into the hanging wall from the face of the lower adit of the Kirchen Mines Co. St. Patrick mine has opened a small body of rich ore, assaying as high as 55% copper.—A pleasing feature of the Congress mine development of late has been the uniformity of ore in the big vein. The east drift for some time has seldom averaged less than 5% copper. In the new vein opened on the 150-ft. level of the Pilot company's Champion mine the sulphide ore is spotty but is of high grade. The Pilot is shipping 25 tons per day.

Luning, January 21.

NYE COUNTY

(Special Correspondence.)—The Tonopah Mining Co. has started shipping 150 tons of mine-ore per day to the Belmont mill, and 300 tons to the Desert mill from its old dumps. It is estimated that sufficient ore is on the dumps to keep the Desert plant working for a year, and after all this material has been treated the old mill at Millers will be dismantled. Portions of the Tonopah mine still containing promising ore will then be opened to lessees. By securing the ore from the Tonopah mine the Tonopah-Belmont Co. is enabled to operate its plant at capacity. This mill is also receiving custom ore from several outside properties.—An examination of the Tonopah Divide mine, at Gold Mountain, has been made by A. I. D'Arcy and H. V. Wittee on behalf of George Wingfield and associates. It is rumored here that the Goldfield Consolidated Co. is negotiating for control of the Tonopah Divide, which has developed splendidly in the past three months. At a depth of 400 ft. a large vein of \$25 gold-silver ore is reported. H. Cal Brounger is principal owner and William Waters is superintendent.—The Consolidated Mayflower Mines Co., operating the Mayflower mine at Pioneer, has started shipments to the Mammoth smelter, at Kennett, following an agreement entered into with the United States Smelting, Refining & Mining Co. The shipping product is being drawn from the 300-ft. level, where ore showing free-gold has been uncovered. The 15-stamp mill is crushing ore from the 200, 300, and 400-ft. levels. Preparations have been made for driving a 1400-ft. drift from the 300-ft. level of the Mayflower shaft to connect with the Starlight shaft. The drift will follow the Mayflower vein, and raises will be extended at intervals to prospect the orebody. Water for the mill is pumped from below the 500-ft. level. W. J. Tobin is manager.

Tonopah, January 20.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Oaks Co. has opened up new ore in the Pacific mine during the past week.—More men are being used at the Socorro plant and construction work is progressing rapidly. It is understood that some type of ball-mill will likely be used for coarse grinding instead of stamps; this will be a change in the Mogollons where stamps have been used steadily for 25 years.—The Mogollon Mines Co. tonnage record for 1917 was one of the largest in its history. While no special changes have been made in the milling process, many

minor improvements have been put into operation.—Belated snows are now falling in mountains, which supply the various mills with summer water.

Mogollon, January 15.

OREGON

JACKSON COUNTY

(Special Correspondence.)—W. A. Sharp of Grants Pass, Oregon, and his brother, L. C. Sharp, of Plattsouth, Nebraska, have purchased the placer land known as the Hydraulic mine, on upper Jump-Off-Joe creek in the north end of Jackson county, from Mrs. Elizabeth Smith of Ashland. It is the intention of the new owners to erect a hydro-electric precipitating plant.—A new find of cinnabar has been reported uncovered in the Trail Creek district, between the Elk Creek and Meadows districts north of Gold Hill, and north of the Lake Creek district.—Much progress is being made on the 900 and 1200-ft. drifts at the Ray & Haff gold mines, two miles north of Gold Hill, which is being operated by J. W. Davies of Sacramento. The 900-ft. drift will open up a large body of ore on a new level, while the 1200-ft. drift will connect with a 1200-ft. drift into the vein from the opposite side of the hill.

Gold Hill, January 15.

(Special Correspondence.)—The Golconda chrome mine at Takilma, owned by Collard, Moore & Collard, which has been idle since September, will resume operation at once under the management of R. J. Rowen, who has been operating in the Gold Hill district for the past two years. He has had a contract for the ore output, but difficulties in production by the owners caused delay and complications which resulted in litigation. Mr. Rowen is being financed in the construction of a mill by the Atlantic Ore & Alloys Co. of Philadelphia, which has purchased the entire output of the mines. This company is to make an advance on ore of \$20,000, which is to be used to erect the plant. Under the present plans the property will be operated with a prospective production of 5000 tons of concentrate annually; this will require the mining of 100 tons of ore per day. The ore, which is all under contract to the Government, will be shipped to Canto, Pittsburgh, and Jersey City.

Gold Hill, January 17.

UTAH

SUMMIT COUNTY

In a letter to the stockholders, Solon Spiro, president, and the directors of the Silver King Consolidated Mining Co., announce that the company has acquired the Ferry ranch, the Silver Bell, Oldham, and Russian Bear groups of mining claims, and the C.-C. Consolidated group of claims and mining and milling equipment. The California-Comstock group of mining claims has been acquired recently for \$300,000, which has been paid, but to raise the necessary amount an indebtedness was incurred that will have to be paid during the present year. The president and directors recommend that the company should increase its capital to meet the indebtedness and provide funds for development and equipment. They are enthusiastic about the company's holdings in the Park City district.

WASHINGTON

SPOKANE COUNTY

The establishment of a large electrolytic antimony plant at Spokane is promised if further tests of such a process on ore are successful. Laboratory experiments on ore taken from the property of the Coeur d'Alene Antimony Mining Co. on Pine creek, Idaho, have encouraged the owners so much that M. E. Jolley, president of the company, says a small factory will be erected at once to continue the tests on a larger scale. It is

said buttons of metal containing 59% antimony have been obtained from the laboratory work.—During the past year 75 tons of high-grade ore has been mined and over 2000 tons of milling ore placed in the bins awaiting the flotation plant.

CANADA

BRITISH COLUMBIA

The annual report of the Consolidated Mining & Smelting Co. of Canada shows a production of metal to the value of \$13,000,000 at a net profit of \$1,976,828. Operations have been conducted at a considerable disadvantage; in the early part of the year strikes at the coal mines caused a shortage of coal, which necessitated the discontinuance of ore shipments from the Rossland mines and curtailment of shipments from the other properties, while toward the end of the year a strike of workmen at the smelter at Trail caused not only the closing of the smelter but of the company's mines. The electrolytic-zinc plant was completed during the year, and a daily production of 60 tons of pure zinc was reached. The total production of electrolytic lead was 22,000 tons, 2000 tons more than in the previous year. The capacity of the sulphuric-acid plant has been doubled, and two new retorts have been added to the hydrofluosilicic-acid plant. A new unit has been added to the Dwight-Lloyd roasting-plant in the lead works; and a flue-gas scrubber, a melting retort, and blue-stone vats were added to the silver refinery, while the furnace and casting facilities at the copper refinery were re-built and re-modeled.

At a meeting of the directors of the Utica Mines, held at the company's office at Spokane on January 12, the president was authorized to increase the capital stock from \$2,000,000 to \$3,000,000 by the creation of 1,000,000 shares of capital stock, par value \$1, fully paid and non-assessable, and to issue \$200,000 of first-mortgage bonds, according to an official announcement. The president also was authorized to negotiate for the purchase of the Sunset and Bell groups in Jackson basin for 800,000 shares of stock and \$70,000 in cash. Of the proposed bonds \$65,000 have been subscribed for in Spokane and British Columbia. The remaining \$125,000 in bonds, or as much of the amount as is necessary to equip the properties, will be taken up by H. H. Armistead, his friends, and business associates in the East. As soon as the money is paid in from the sale of the first \$100,000 in bonds, the Utica company will take over deeds to the Bell and Sunset group of mines, when 2,400,000 shares of the 3,000,000 shares will be issued and 600,000 shares will remain in the treasury. The company will own 18 full and fractional crown-granted claims, a mile square of timber-limit, and two water-power sites. There are nine known ore-shoots on the properties. The No. 7 adit on the Utica mine is now in 2000 ft. and will develop four ore-shoots to depths of 350 to 1600 ft. below the lower workings. These four shoots vary from 500 to 750 ft. in length and from a few inches to several feet in width. They contain a high-grade silver-lead ore averaging 150 to 250 oz. silver, 20% lead, and 17% zinc. The lower adit of the Sunset group, now in 1800 ft., will cut what is known as the west ore-shoot on the Sandon side of the mountain at 270 ft. below the lowest workings. This shoot of ore has yielded several hundred thousand dollars worth of silver-lead ore averaging 60% lead and 15% oz. silver. The Bell adit, driven from the Jackson Basin side, or the east side of the mountain, has developed the Bell zinc ore-shoot, which is 35 ft. wide at a depth of 100 ft. from the surface and when advanced will gain an additional depth of 100 ft. from the ore-shoot. The shipping ore averages 45% zinc and the whole 35 ft., 25% zinc. An adit has been driven westward from a point 250 ft. from the mouth of the Bell adit that should cut the east lead-silver ore-shoot on the Sunset vein 250 ft. below the lower workings. A 9-ft. body of silver-lead ore has been uncovered on the property of the Galena Farm Mining Co. in the Nelson mining district.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

L. C. TRENT, of Los Angeles, is here.
 GEORGE H. SEXTON is here from New York.
 ROBERT T. KINZIE has returned from Mexico.
 STUART H. INGRAM has gone to Marysville, California.
 CHARLES E. PICKETT is in the 5th Field Artillery, U. S. Army.
 GEORGE H. GARREY arrived in San Francisco this week from Philadelphia.
 F. J. STRACHAN is now with the Cananea Copper Co. at Cananea, Sonora, Mexico.
 GEORGE H. HYDE, of Ridgway, Pennsylvania, is on his way to Sacramento, California.
 CHARLES SIMENSTAD has opened an office as consulting engineer in L. C. Smith Bldg., Seattle.
 J. ROWLAND EVANS is visiting at Butte, after spending six years in the Belgian Congo, West Africa.
 DANIEL G. McLACHLAN is superintendent of the Armstead mines at Talache, on lake Pend Oreille, Idaho.
 W. E. THORNE, for three years advisory engineer to the Lena Goldfields, in Siberia, has returned to San Francisco.
 PERCIVAL P. BUTLER, formerly with the Copper Queen smelter, is now superintendent of the U. V. X. smelter, at Verde.
 B. MAGNUS, now with the American Metal Co., at New York, is here on his way from Joplin, Missouri, to Trail, B. C.
 W. H. LANDERS, Captain in the Engineer Reserve Corps, is now with the American Expeditionary Force in France.
 E. G. SNEDAKER is First Lieutenant in the 4th Regiment of Engineers now stationed at Camp Greene, North Carolina.
 E. G. MONTGOMERY, superintendent for the Consolidated Mining & Smelting Co., at Rossland, has been examining mines near Hedley, B. C.
 F. L. RANSOME, of the U. S. Geological Survey, is in San Francisco, on his return from an inspection of the quicksilver mines of California.
 W. SINCLAIR BROWN, having resigned as chief metallurgist to the Redjang Lehong company in Sumatra, is returning to San Francisco early in March.
 S. A. LANG, formerly with the Braden Copper Co., at Rancagua, Chile, has been given the commission of Lieutenant in the Canadian Engineers, C. E. F., and is at St. Johns, Quebec, Canada.

Obituary

ALLMAND A. BLOW died at Knoxville, Tennessee, on January 2. We announce the fact with deep regret. On January 14 the Board of Trustees of the Colorado School of Mines passed a resolution stating: Resolved, That the Board of Trustees, the faculty, and the student body of the Colorado School of Mines place upon the records of the institution their marked appreciation of the deceased as a citizen of liberal education and wide usefulness, as a mining engineer who added greatly to the reputation and service of his profession in four continents and as a member of the Board of Trustees whose connection with the Colorado School of Mines was made prominent by that loyalty and earnestness of conviction which brought loyalty and conviction in his colleagues. As the originator of the great Yak tunnel in the Leadville district the name of Allmand A. Blow is impressed for all time upon the annals of Colorado mining, while his early publications under the auspices of the Colorado School of Mines, prepared the way for the present importance and value of the zinc-bearing ores in the Rocky Mountain States.

THE METAL MARKET

METAL PRICES

San Francisco, January 22

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	16.00
Antimony (wholesale), cents per pound.....	14.75
Electrolytic copper, cents per pound, in carload lots.....	23.50
Electrolytic copper, cents per pound, in small quantities.....	24.67½
Pig-lead, cents per pound.....	7.00—8.00
Platinum, soft and hard metal, respectively, per ounce.....	108—116
Quicksilver, per flask of 7½ lb.....	\$125
Spelter, cents per pound.....	10.00
Zinc-dust, cents per pound.....	20.00

ORE PRICES

San Francisco, January 22

Antimony, 45% metal, per unit.....	\$1.00
Chromite, 34 to 40%, free SiO ₂ , limit 8%, f.o.b. California, per unit, according to grade.....	\$0.60—0.70
Chromite, 40% and over.....	\$0.70—0.85
Magnetite, crude, per ton.....	\$8.00—10.00

There is little demand for either calcined or crude magnesite.
 Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.
 Tungsten, 60% WO₃, per unit..... 26.00
 Tungsten ore remains firm.
 Molybdenite, per unit MoS₂..... \$4.00—15.00

EASTERN METAL MARKET

(By wire from New York)

January 22.—Copper is quiet and unchanged at 23.50c. all week. Lead is dull and firm at 6.90 to 7c. Zinc is inactive and steady at 7.87c. all week. Platinum is higher at \$108 for soft metal and \$116 for hard.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending

The Board of Managers of the New York Metal Exchange recently adopted a resolution amending the tin contract so that hereafter all tin contracts will be subject to this resolution which practically provides for immunity to the seller in case of force majeure and permits postponements of maturities in such event until the seller is able to comply with terms of the contract.

*As reported by the Directors of the U. S. Mint and the U. S. Geological Survey.

Eastern Metal Market

New York, January 16.

The markets continue quiet and featureless. The publication of estimates of the 1917 output of copper, zinc, and lead, has excited some interest.

Copper is quiet and unchanged.

Tin is scarce for spot delivery and nominal.

Lead is not in active demand, but it has advanced.

Zinc continues in poor demand, but its price is nearly stationary.

Antimony has gone to lower levels in a dull market.

Bad snowstorms have added to the serious congestion on the railroads and the result has been a decided lessening of steel-mill and blast-furnace output. In the Chicago district the total pig-iron output has been 30 to 40% of normal, with the steel production somewhat more. This curtailment in steel output may mean a tighter drawing of the lines against less essential industries in the distribution of mill products, thus diverting more labor to imperative Government needs. Some large inquiries for shell-steel for the British government have appeared, and also one for plates.

COPPER

The market is proceeding in an orderly manner under the extraordinary conditions imposed by Government control. With the usual processes of buying and selling and the attendant speculation removed, there is little news, and the market is featureless. A fair business is reported for both Government and other uses at the controlled price of 23.50c. per lb. for carload and larger lots, and at 24.67½c. for less than carloads. There seems to be an ample supply, with consumers receiving all they need, and with satisfaction quite general. The publication of the U. S. Geological Survey's report showing the 1917 output of refined copper in the United States to have exceeded all previous records has put a damper on agitation for an advance in the Government price from 23.50 to 25c. per lb. The total 1917 output is estimated at 2,362,000,000 lb., against 2,259,000,000 lb. in 1916 and 1,615,000,000 lb. in 1913. The only new feature of the week is the published unofficial statement that an agreement has been reached between the Government and the Copper Producers' Committee, assuring the maintenance of the 23.50c. price until May 1. It is asserted that an official statement from the President, expected every day, will confirm this rumor.

TIN

An important resolution was passed by the New York Metal Exchange on January 10, which places the burden of all risks, attendant on the unparalleled shipping and railroad situation, on the buyer of tin, and it is probable that this will become a part of all contracts. During most of the past week, with the exception of yesterday, the market for futures has been active. Each day a good demand has appeared, which has resulted in considerable business. Delayed cables on one or two days seriously interfered with business. Yesterday the market was quiet. Spot tin of all kinds continues practically unobtainable, with quotations nominal at \$5 to 86c., New York, for Straits. For Straits shipment from Singapore in March 69 to 69.50c. is quoted, with April shipment at 68.50 to 68.75c. Chinese No. 1, January shipment, is held at 62.25c., with February at 61.50c. England continues to hold up all shipments of Straits tin. Efforts here to change this have not resulted in success so far, though they are still progressing. Tin arrivals so far reported have been 460 tons, with 5500 tons reported afloat. Spot Straits in London yesterday was quoted at £299 10s. per ton against £282 on January 1.

LEAD

Another advance has been put into effect by the American Smelting & Refining Co. On Friday, January 11, it added ½c. to its quotation, bringing it to 6.75c., New York. The outside market has also advanced to 6.90c., New York, or 6.75c., St. Louis. The trust's advance is the second in the last two weeks, the first one having been ½c. on January 3. The reason for this is not clear to some, as it is not warranted by an active demand nor by a scarcity of lead. There is considerable speculation as to the real reason. The market as a whole is quiet but firm. Most of the consumers are not compelled to enter the market, and most of the sellers are not offering. One dealer has had metal in transport from the West since November, and has lost all trace of it. Transportation problems are serious, and are said to be as bad or worse than they were a year ago.

ZINC

The only interesting news of the week has been the estimates of the 1917 output of spelter. That of the U. S. Geological Survey puts last year's output at 667,751 tons, while other statisticians place it at about 18,000 tons higher, or 685,400 tons. The explanation of this variation is probably found in the fact that the latter computation includes secondary spelter re-distilled at some large smelting plants. The interesting fact, however, is that the 1917 output was about the same as that for 1916, whereas it was generally expected, at least by those not actually on the inside, that a decided curtailment had taken place. These facts may explain the inactive or generally weak market that has existed for some time and that continues to exist. Prime Western for prompt or early delivery is quoted at 7.62½ to 7.75c., St. Louis, or 7.87½ to 8c., New York. Sales have been made at the lower levels, but the volume or importance is not consequential. Yesterday there were small sales for early February delivery at 7.75c., St. Louis, or 8c., New York, and it is stated that the tendency to scalping is not as marked as formerly. Stocks on hand or in transit at the end of 1917 were 50,107 tons, according to the Survey, and 60,000 tons according to other estimates. The surprising and significant fact is that these exceed those of a year ago by only 17,598 tons.

ANTIMONY

The market is lower, with spot metal duty paid, New York, quoted at 14 to 14.25c. One lot of 50 tons was sold a few days ago at 14c., New York, duty paid. An explanation of the poor demand for antimony is that anti-friction alloy makers have been producing at a low rate and consequently have been using less antimony. The possible Government order for 200 to 300 tons, referred to in a previous letter, is understood to have been placed.

ALUMINUM

The market is quiet with No. 1 virgin metal, 98 to 99% pure, quoted at 36 to 38c. per lb., New York, for prompt and early delivery. It is stated that the Government may fix the price of aluminum at a lower level than that of 38c. as the contract price of the leading producer. Some say that the 1918 output will be 35% larger than that for 1917.

ORES

Tungsten: The general railroad congestion has interfered with normal business. One dealer affirms that he has had ore for export on the way from the West for over two months, with vessel space twice engaged and cancelled. But little business in the week has been reported. Prices are nominal at \$24 to \$26 per unit in 60% concentrates, depending on the ore.

Book Reviews

A TREATISE ON THE ELEMENTS OF ELECTRICAL ENGINEERING. A text-book for colleges and technical schools. By Wm. S. Franklin. Vol. I. Pp. 465. Ill. Index. The Macmillan Company, New York, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$4.50.

This is a companion to the work by the same author entitled 'Electric Lighting and Miscellaneous Applications of Electricity', which, as re-printed, will constitute Vol. 2 of 'The Elements of Electrical Engineering', thus making a very complete résumé of the essentials of practical electrical operations of the day. The present volume is divided into three parts, the first reviewing elementary and applied electricity and magnetism, which deals with ferro-magnetism and electro-magnetism, heating-effect of the electric current, induced electromotive force, the electric field, the electron theory, and other subjects. Part II deals with direct-current machines and systems, and plunges at once into the practical side of the question. Part III develops the elementary theory of the alternating-current, and Part IV deals with alternating-current machines and systems, including the alternator as a generator and as a motor, the conversion of alternating to direct-current, with problems and solutions, transformers, the induction-motor, the single-phase commutator-motor, and the general theory of transformers and induction-motors. While it deals with the simple physics of the subject, it must be stated that the use of the work requires a knowledge of calculus.

HEAT. By John Roger. 12mo. Pp. 77. Publishers Printing Co., New York, 1917. Privately printed.

The thesis presented in this book may best be summed up in the prefatory words of the author. He says that "Heat is a diamagnetic or negative force acting in opposition to the positive force of atomic attraction; that temperature is the negative atomic stress produced between the atoms; that the work-value of a unit of heat is 778 foot pounds, but is proportionate to the temperature; that the unit of energy, 778 foot pounds, may apply anywhere on the scale of temperature without reference to the unit of heat; that there is no such thing as latent heat, but that there is only developed and undeveloped energy; that the properties of different forms of matter can be compared by quantities of equal weight, but that the specific heat of different materials should be dealt with by equal volumes." He further affirms that "Gases do not expand proportionately to their pressure per square inch, but when expanded adiabatically the pressure varies inversely as the square of the distance between the atoms." He distinguishes between a gas and a vapor by a difference in the intensity of the force of attraction between the atoms, and he points out that the specific heat of matter has no apparent relation to the atomic weights. Since this is the work of a trained and highly accomplished physicist and mathematician, who yet knows how to use language as an expression of mathematical ideas without resort to symbols, which is a rare mental qualification, it is certain that Mr. Roger's book will be demanded by a large and interested public.

HEATON'S ANNUAL, 450 pp., price \$1.25, published by Heaton's Agency, Toronto. Of the new features we notice a list of titled and decorated Canadians, which the War has swelled to several pages, and under the heading of 'Commerce' is an interesting compilation of the pre-war imports from enemy countries into Canada, which will be a useful guide to firms considering the establishment of a new industry in the Dominion. At the end of the book a new section under the heading of 'Colonization' gives some interesting and valuable information that has not been collected before; here we find under each Province land available for farming; fruit farming; cat-

tle and sheep ranching; crown land regulations; financial assistance given to farmers by Provincial and Dominion governments; and special provisions for returned soldiers.

The first part of the book contains the official directory; postal information; shipper's guide; commercial regulations; railway and steamship guide; and customs tariff. In the last half is a complete up-to-date summary of the resources of the Provinces including agriculture, canals and waterways, commerce, education, finance, fisheries, forests, fur farming, mining, and water-powers. This is followed by the official Boards of Trade Register giving descriptions of every commercial town in Canada with its industrial opportunities. References are given throughout the text to a section entitled 'Where to Find It.' This contains a guide to the more important Dominion and Provincial government reports and standard publications from which all available information on any subject can be obtained. Cross references are given to this section throughout the text.

Announcement

The Dean of the University of Illinois announces that twelve fellowships in research engineering and two in research gas engineering will become vacant at the end of the current academic year. These fellowships run for two years, carry an annual stipend of \$500, and, if all requirements have been met, the degree of Master of Science will be conferred. Further particulars may be obtained from the Director, Engineering Experiment Station, University of Illinois, Urbana.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

PACIFIC ELECTRIC SPOT-WELDERS

Electric spot-welders, which are rapidly superseding the older methods of riveting iron, owing to their economy in material, time, and labor, are now being manufactured by the Pacific Electric Welder & Manufacturing Co. of Seattle, Washington. The company has many of its welders operating in various manufacturing establishments of the United States as well as in Japan and Australia. It is gratifying to note that this company has developed an important export business with Japan and Australia for the sale of its welders. The welders

PACIFIC ELECTRIC SPOT-WELDER TYPE S-A-10

are suitable for various classes of work in sheet metal and ornamental iron shops, stove manufacturers, shipyards, etc., and will readily be found an indispensable piece of machinery to manufacturers now engaged in riveting various articles of metal, owing to its great saving in time, labor, and material, as well as its current consumption being less than the cost of rivets.

The electric spot-welder is very simple in operation. It is the joining or fusing together electrically of two or more metal sheets or parts without any preparation of the stock used. Mechanically it is equivalent to riveting, but it is stronger and much quicker and more economical. By placing the materials between the electrodes or welding-points where it is desired to make a weld, then, by applying pressure either with the

hand or foot-lever, the metals are pressed together, electrical contact is instantly made, and the weld is accomplished; wrought steel and galvanized iron are the best materials for electric welding.

Two standard types of various rating are manufactured by the company. One type is adapted to work on clear stock measuring 30 to 11 gauge, or welding a combined thickness of one-quarter inch, while the other is for 30 to 3-gauge materials, or a combined thickness of one-half inch. Special welders to meet the requirements of various classes of work can also be manufactured. The company has many letters from manufacturers now using the welders, which tell of their merits. The plant erected by the company is a substantial structure consisting of about 30,000 sq. ft. of floor-space, and, taking its present demand for the welder as a basis to judge, it is destined to become one of the leading manufacturers on the Pacific Coast.

BLASTING SOOT OUT OF A STACK

Sooty smokestacks are wasteful of fuel. A safe and economical way of cleaning them by the use of blasting-powder is suggested by the Du Pont magazine. For this purpose a 'gun' is used, made of an old piece of pipe-shafting about 4 in. diam. and 14 to 16 in. long. A hole $1\frac{1}{2}$ in. diam. and 10 in. long is bored in one end of this shafting, converting it into a small cannon-like arrangement, and a touch-hole $\frac{1}{4}$ in. diam. is bored through the side about 9 in. from the end, connecting with the centre bore and serving for the fuse. This gun is then mounted on a pedestal 6 in. diam. to hold it upright. The method of operation is as follows: Pour blasting-powder into the mouth of the cannon to about 2 in. from the top. Tamp to the collar with dry clay. A short piece of fuse is inserted in the touch-hole and in contact with the main powder-charge. Open the flue-door at the bottom of the stack, set the cannon on the bottom, and in the centre of the stack, light the fuse, and close the flue-door. The explosion shakes and loosens the soot adhering to the sides, causing it to fall to the bottom. It can then be removed through the flue-opening. A charge of 8 in. of PFF powder, $1\frac{1}{2}$ in. diam., is sufficient for a stack up to 100 ft. high and 4 ft. diam., or over. The number of shots necessary to thoroughly clean a stack depends upon its condition. Ordinarily three or four shots will be sufficient, but if very dirty it may require more. The size of the charge and length of the cannon can be regulated to suit the height and diameter of the stack. There is no doubt as to the efficiency of this 'gun' for cleaning smokestacks. One of the largest manufacturing concerns in the country has used this method for several years without an accident or injury in any way to the stacks.

FOREIGN TRADE CONVENTION

The National Trade Council will hold its 5th National Foreign Trade Convention at Cincinnati on February 7, 8, and 9. The chairman of the Council is James A. Farrell, president of the United States Steel Corporation, and the chairman

of the local Cincinnati committee is Robert S. Alter, vice-president of the American Tool Works Co. The chairman of the physical arrangements committee is A. B. Fishwick, 812 Commercial Tribune Bdg. In his call for the convention Mr. Farrell says:

"American participation in the war against Germany has laid a new obligation upon the foreign trade enterprise of the United States. To give serious thought to the demands and problems of the future, delegates from every part of the United States, representing all phases of commercial and civic development, will assemble for the three days' session at Cincinnati. It is our duty, as never before, to see that the flow of overseas commerce proceeds with uninterrupted regularity and in the largest possible volume, steadily bringing to us the products necessary to the enterprise on which we are embarked, and steadily carrying to our Allies, the materials and manufactures that will enable them to maintain their efforts." It is an appropriate moment for serious men to discuss the larger aspects of future trade in the light of possible plans for a world-peace. The world will not relapse into the old accustomed groove. Men who think in terms of the old ways of conducting business simply are not thinking. We may talk of foreign credit, which is one of the subjects to be discussed at the convention, but no man can present a sound view of future credit-relations without considering at the same time the basis on which trade between the nations may be re-established after the War. That is to bring up the whole issue of war-aims. If we have reached a dogged determination to eliminate Teutonic power as a unit-factor in world-affairs then we can rehabilitate the family of nations on the broad secure foundation of national trade and amity if we so desire,

TRADE-MARKED SUPPLIES

When, after thorough investigation, an engineer or architect is convinced that a certain article or material is exactly suited to the needs of his clients it would seem that he should say so without hesitation or further discussion. To specify what is right, 'or equal', in the first place discredits the engineer's judgment and experience and is a tacit admission that he may have committed a technical error in specifying a particular article. From the time this iniquitous clause is made public until construction is practically complete it is important to keep within the spirit of the specifications. He must use his own judgment as to a possible substitute just as he presumably did when first drawing up the specifications. After such reflection, the old excuse that the 'or equal' clause is inserted to give others a chance and to prevent charges of favoritism loses its potency. Such accusations are as old as tradition, and should have no weight where motives are just and sincere. When a reputable doctor prescribes a given drug under given conditions no one thinks of charging him with partiality toward its manufacturer. But when a certain article or material has been selected, how is the inspector to know that no substitution has been made by an unscrupulous contractor or dealer? In these days of clever imitation even the most experienced superintendent may be readily deceived by mere casual inspection, and exhaustive tests of each item during construction are impracticable. The only satisfactory answer to the dilemma seems to be the exclusive use of trade-marked material, or materials which are clearly marked as to quality or grade by the manufacturers. An article that is not good enough to be trade-marked, or bear evidence of grade backed by the maker, is not good enough to specify. Aggressive manufacturers in nearly all lines of trade have found some method of distinguishing their products and thus have accomplished what might be termed four-fold protection. By preventing substitution of another article for that of their own manufacture, they assure to themselves the full benefit of their extensive advertising, they assure to the consumer the satisfac-

tion for which he is paying, they assure to the engineer certainty and ease of identification, and they assure to the contractor and dealer freedom from possible charges of dishonesty. —Abstract: 'American Architect.'

COMMERCIAL PARAGRAPHS

THE SMOOTH-ON MANUFACTURING Co. has just issued a booklet entitled 'Extracts from Instruction Book,' No. 16, showing the application of 'Smooth-On' for mending breaks of water-pipe subject to high pressure, as well as the use of this valuable material in making tight joints, surfacing concrete floors where heavy traffic is to be resisted, and in filling open joints in iron and steel work where a material that is hard and non-shrinkable is required.

'Protective paint costs less than rust-catastrophe,' is a saying of the JOSEPH DIXON CRUCIBLE Co. In 'Graphite,' the organ of the house, in the November issue, is illustrated the viaduct of the Fort Smith Light & Traction Co. at Van Buren, Arkansas, painted in 1914 with Dixon's silica-graphite paint. The paint is still in good condition, despite the fact that the structure spans railroad tracks and is subject to severe conditions of smoke, heat, dust, and abrasion.

'Everything for Mine and Industrial Safety' is the title of an elaborate catalogue issued by the MINE SAFETY APPLIANCES Co. of Pittsburgh. It gives in detail the description of first-aid equipment and supplies, according to the latest practice, with specifications for ordering, and prices. Among other appliances illustrated and described are portable electric mine lamps, gas detectors, the 'Fleuss Proto' self-contained oxygen breathing-apparatus for mine-rescue work, ammonia masks, shot-firing batteries, the Johns-Manville fire extinguisher, post-pullers, anemometers, water-gauges, hygrometers, safety ladder-shoes, horse-shoe magnets, mine telephones, and signal apparatus, the Davis flood-light, oxygen cylinders, and a large number of other appliances which are in growing demand with the spread of the propaganda for increased safety.

The first death among the 1624 employees of the B. F. GOODRICH RUBBER Co. that have enlisted since the outbreak of hostilities is that of Ensign P. W. Page. He was particularly well known in the Eastern automobile field. Ensign Page was drowned off the coast of England, according to word reaching the tire corporation, when his sea-plane became unmanageable and plunged into the sea. He has been in the service of the United States since May 4. He had been in the employ of the Goodrich company since September 3, 1913. He came to them from Harvard University. He had always been interested in aviation, and during his college days made many flights. He remained at Akron until March 10, 1914, when he was transferred to the Cincinnati branch, working from that point as a traveling representative until April 1, 1915, when he became manager of the Portland, Maine, branch. On March 6, 1916, he was called to the Boston branch, and was assigned to cover western Massachusetts and southern Vermont. Shortly after the outbreak of war he resigned to enter the naval branch as an aviator. Officials of the Goodrich company deeply regret his death. He possessed an enviable reputation as a man and as a representative of the organization.

Stephen G. Murray, for many years general Western representative of the INGERSOLL-RAND Co., died in San Francisco on Sunday, January 6, at the age of 64 years. Mr. Murray had been in the service of the Ingersoll-Rand Co. and its predecessor, the Ingersoll Sergeant Drill Co., for over 30 years. He had, for the last 20 years, spent most of his time in the West, particularly in San Francisco, Salt Lake City, Butte, Seattle, and Juneau, where his many friends will learn with regret of his death. He leaves a widow.

EDITORIAL

FLOTATION litigation will be expedited by the hearing of the case of *Minerals Separation v. Butte & Superior*, which comes up on appeal before the Ninth Circuit Court of Appeals, in San Francisco, on March 8.

WE publish an interesting article describing the use of ordinary sea-water as a frothing-agent, a recovery of 92.88% of copper being obtained on a chalcopyrite ore. Our readers are aware that patents involving the use of alkaline chlorides have been granted to Messrs. F. J. Lyster, Leslie Bradford, and others. All of these patents, we believe, have been acquired by Minerals Separation. The question arises, can you prevent a man living at tide-water from using the ocean or a man in the interior from employing the waters of a saline lake in his metallurgical operations?

GREAT BRITAIN has just signed a new treaty of commerce with Spain, after many months of negotiation, whereby Great Britain is entitled to draw from Spain all the iron ore and pyrite that she can obtain by operating mines, or by purchase in the open market, in exchange for the right to import into Spain 150,000 tons of British coal, 300 tons of tin-plate, and 120 tons of ferro-manganese per month. The treaty has reference also to exchanges of food-products. The Spanish newspapers express dissatisfaction over the failure to secure the right to purchase ammonium sulphate from England, but it is apparent that no nitrogenous products could be spared during the War. Spain must have recourse to by-product coking of the coal from her rapidly developing mines for a domestic source of ammonia. In so doing she will benefit her own people.

ZINC mining has suffered from a spasmodic market, which just now looks sickly. Probably one-third of the spelter plants are idle, owing to the low price of the metal. The New Jersey Zinc and the American Metal companies are producing one-fifth apiece of the total output. At a price of \$17 for roasting and distillation of a 40% concentrate, on an 84% recovery, the cost is 2.6 cents per pound. The refining costs 1½c., but only 40 to 45% of the retort-product has to be re-distilled, so that 0.5c. covers that item. A 60% concentrate is purchasable for \$54. Allowing for a recovery of 1000 lb. of zinc, the cost

is 5.4c. per pound; but \$12 to \$13 per ton of concentrate must be credited for the sulphuric acid that is made as a by-product, so that the purchase price is reduced to \$41.50, making the cost of the zinc 4.15c., which, added to the cost of treatment, makes 7.25c. as the total. This would give the smelter a margin of 0.62c. on the current quotation. The miner, at Joplin, for example, that sells his concentrate for \$54 is making from \$5 to \$10 per ton on a 50% concentrate, or about 0.75c. per pound of zinc. On the face of it the miner and the smelter are dividing a profit of about 1½c. per pound, but we suspect that the smelter holds the longer end of the stick. Several weeks ago we referred to the peculiar difficulties that have beset the zinc industry since our declaration of war. The needs of the Government for copper were ascertainable, and a fair price was established, but no indication was given as to the probable war-demand for zinc. The producers have now held a conference with the Council of National Defense, urging Government action to stabilize prices. In the interest both of conservation and preparedness an official forecast would seem desirable, in order that zinc mining be regulated on an economical basis.

OUR contemporary at New York publishes two obituary notices, of A. A. Blow and William Hague, that will be read with sympathetic appreciation. These two friends of ours were not among the notorieties created by a cheap press and predatory finance, but professional men of the highest character, in whom technical ability and intelligent initiative were joined with those higher qualities that make a man a good husband and father first and then a good citizen. In age nearly a generation apart they were guided alike by those high principles and the love of doing work for the sake of doing it well that distinguish the professional man from the mere laborer. Blow proved himself a forceful and capable engineer at Leadville before he went to South Africa, where, as manager of the celebrated Sheba mine, he did honor to the American branch of the profession, both as technician in designing a mill and as director of a large force of Kaffirs. His two stalwart sons, one of them in the Army, will perpetuate a tradition of good citizenship. Hague went into military training before war was declared by the United States, so that he was ready, as

well as willing, to volunteer instantly for military service when the call came. His example led 54 men at the North Star mine, at Grass Valley, to enlist. While at American Lake he caught a severe cold, from which he had not recovered when about to start for France. None of us, however, was prepared for the news of his death by bronchial pneumonia. At the last meeting of the local section of the Institute several members took the opportunity to pay a tribute to his memory. He was the worthy son of a good and useful man; like him, an engineer and a gentleman; a straight, clean, strong character. His influence will remain and his memory will be one of the fair things left from the wreck of warfare.

UNDER the collective name of 'Scientific Nominalism', Mr. Dudley Norris presents a formidable array of words and phrases that have been used in published attempts to explain in scientific fashion how the phenomena of flotation are caused by electricity; and by his philosophic examination of these words and phrases he undertakes to prove that they are names and nothing more. In his review of the flotation litigation Mr. Norris credits Minerals Separation with the invention of agitation to form a froth, stating that it was the result of a capricious acceleration of the Gabbett mixer to an abnormal degree to see what would happen. We impute the origin of froth-flotation to the work done in the Central mill, at Broken Hill, in 1903 and 1904. Aside from this one feature Mr. Norris denies any further invention by Minerals Separation, and credits Mr. Ballantyne, Mr. Ballot's patent lawyer, with having adapted from the Elmores, with whose work Mr. Ballantyne was familiar, the diminished proportion of oil and other features of the Minerals Separation patents. He considers that Mr. Ballantyne's specification and claims were drawn with a technical skill conspicuously absent from those of the infringing defendants. The latter undertook to supply the deficiencies in their patents by numerous and elaborate physical tests and scientific demonstrations of the various processes, but unfortunately for them they met with a judicial psychological condition that militated against their best efforts. Mr. Norris shows the development of the inductive and the deductive systems of logic in ancient Greece, and suggests that the legal profession, including the judges on the bench, are trained in deduction to the exclusion of induction, which is the method of the physical sciences, with the result that even Aristotle, the father of deductive logic, was intellectually color-blind in the presence of the problem of the falling bodies, his decision that the larger body would fall the faster remaining unchallenged for centuries until Galileo, the champion of induction, proved its fallacious character. We accept the pleasant lucubrations of Mr. Norris as making for the dissipation of fog and an increase of good-natured sanity. Another generation will laugh at the pretensions of Minerals Separation, which could not explain the physics of the invention it claimed to have made, though it will be less easy to forgive than the

nominalistic errors of Heraclitus, who really did grasp a great truth when he conceived all that exists as a perpetual becoming, and its progress the conversion of state as expressed in 'fire'. He recognized the germ-principle of the eternal forward movement, which Bergson has so splendidly adapted to the modern view-point in the light of biologic revelations.

NEWS is not coming out of Mexico these days as freely as it did when the opposing factions were fighting each other through the American newspapers as a means of gaining help for their military struggles. Carranza has been maintaining a news bureau that is not altogether clever, since the stories of progress and development issued to the public are too extraordinary to be credited by men of understanding. Meanwhile, information of quite another order filters steadily through the screen of censorship along the border. We hear of a serious clash between Carranza and the Congress over his bill for a single bank of issue, based upon imaginary assets. It was a wild scheme, and so certain to destroy what little credit Mexico had regained by her salutary return to metallic currency that the Congress, in order to escape official brow-beating, adjourned. Carranza retaliated by holding up the treasury warrants of the deputies for salary and mileage. This act evidently brought reprisals, for we hear of Carranza's sudden departure for Queretaro, where he has prudently remained for several weeks. Rumors of new revolutionary enterprises are rife, and even 'Las Novedades,' the faithful advocate of Carrancism in this country, admits that trouble is brewing, and that two of Carranza's generals, Francisco Coss and Luis Gutierrez, heretofore counted among the strongest adherents of the Government, have taken up arms in opposition. Obregon appears to have definitely 'retired,' whatever that may mean or may signify. On the other hand, Carranza finds cause for congratulation over the utter collapse of the revolution started by General Juan A. Almazan in Nuevo Leon, that campaign having failed to enlist the sympathy and support of the anti-Carrancistas. Private information from numerous travelers returning from Mexico leads to the conviction that no such thing as law and order exists, and that the policing of any district and the quality of justice meted out depend entirely upon the personality of the local authorities. Even in the Persia of Hajji Baba there was sometimes to be found a measure of humanity and fair-dealing, mixed with an official eye to personal pecuniary advantage, that would enable a clever man to attend to business without being denounced to the *cadi*. It would be good to believe that Señor Garcia Vigil was voicing a changed spirit on the part of Mexico, and that he was speaking for his fellow deputies the other day in the Mexican congress when he announced that the proper place for his countrymen was at the side of the United States in this world-war, as an evidence of gratitude to President Wilson for having lent his potent aid to the Carrancistas, without which they never could have

triumphed. The spread of such sentiments would indicate the dawn of reason, which would speedily terminate the scandalous condition that now embarrasses the friendly relations between the two countries when every German spy, on being hotly pressed by our detectives, escapes to Mexico, where he seems to count on a cordial welcome and on liberty to continue safely to plot against the United States.

THOSE who have been complaining about conspicuous incompetence at Washington may congratulate themselves. The protests they have made have caused the Administration to do the obviously practical thing that should have been done last April. We refer to the appointment of Mr. Edward R. Stettinius as surveyor-general of Army purchases. The title may be somewhat vague, and it was apparently meant to be; nevertheless the critics who have seized upon this matter of mere nomenclature as indicating a purpose to retain the old order are likely to be surprised. Incompetence had been so fully demonstrated that the Administration either had to take refuge in the appointment of an acceptable administrator of purchases, or enter into a bitter struggle with Congress over the creation of a special triumvirate or 'war cabinet.' An administrator of purchases was manifestly the less embarrassing of these alternatives, and the choice fell happily upon the logical man for the position. Mr. Stettinius has a reputation for success behind him that is too valuable to be put in jeopardy. He will be no figurehead; he will organize the work on a basis of efficiency or he will resign. The entire country has applauded the appointment; the incumbent will be given a free hand because the Administration dare not let him retire; to suffer that would be a more damaging criticism than anything Mr. Roosevelt or Mr. Chamberlain has said. It is a pity that the President should have waited so long before taking this step. The well informed were amazed that no advantage was taken of the great organization that had been created by J. P. Morgan & Company, under the immediate direction of Mr. Stettinius, to purchase war supplies for England and France. Here was a body of capable business men possessed of invaluable experience in buying, assembling, and shipping munitions and materials for war; they had performed this service so well that they possessed the implicit confidence of the governments whom they served as agents; they knew the sources of every commodity needed; they were intimately acquainted with the capacities of a multitude of manufacturing plants, and were familiar with the capabilities of the men controlling them. They were fitted to expand their organization to cope with the enlarged responsibilities of supplying our own Government in the crisis of war. It was almost unbelievable that the Administration would fail to commandeer this splendid organization, but the opportunity was ignored. A vain and muddled effort was made to form a new organization. The whole immense responsibility of placing orders for ourselves and the Allies was

assumed by the Government without calling upon these tried specialists for advice. Confusion, delay, and economic waste have been the result. Self-sufficiency cannot successfully replace efficiency; therefore it is cause for thankfulness that the light has dawned at last upon official Washington.

Mining in Russia

Russian misrule does not appear to have affected the Kyshtim, Tanalyk, and Irtysh corporations as much as might have been feared. These large and important mining enterprises, in the hands of English and American engineers and capitalists, have survived the effects of the revolution because the actual mining and smelting operations are in Siberia, far from the centres of political ferment, and also because the Anglo-American directorates in London co-operate on the most friendly terms with the local Russian managements. The ore-reserve of the Irtysh Corporation, operating the Ridder and other zinc-lead mines in the Altai, is stated to represent \$65,000,000 in probable profit. A discovery of 30-dwt. gold ore, 200 feet wide, is said to have been made recently on the 140-foot level of the Sokolui mine belonging to this corporation. The Tanalyk is said officially to have \$12,500,000 profit assured. The Kyshtim produces from 6000 to 8000 tons of copper per annum and has large resources of ore. At the recent annual meetings of these companies it was announced that the shares in the Russian companies, which are the operating units as against the English holding companies, are now vested in the Russo-Canadian Development Corporation, with a view to prevent the transfer of stock to inimical interests. Whether the selection of this Canadian company was influenced by the expectation of evading taxation in England is not clear. The administration of the combined business will be in the hands of 15 trustees, among whom we recognize the following American mining engineers: R. Gilman Brown, T. J. Jones, and D. P. Mitchell. These have worked loyally, for many years, with Mr. Leslie Urquhart, the originator of these Anglo-American enterprises, a man whose unusual sagacity and energy have been aided by the fact that he was born in Russia and understands the people of the country. It appears that, by purchasing large stocks of food, boots, and other essential commodities, these companies have been able to take care of their work-people and to retain their goodwill, despite the efforts of the Bolshevik element to make trouble. Another obstacle to strikes and disorder lies in the fact that these mines are in parts of Siberia where the Bashkir and Kirghiz tribes of Turcomans predominate, and where the more nearly Russian element is represented by the Cossacks—all three peoples possessing hereditary rights and private ownerships that are menaced by the "socialistic ravings of madmen and the greed of the landless proletariat of the towns," as expressed by Mr. Cater Scott, the chairman of the Kyshtim Corporation.

The community lands of the Bashkirs and the Cossack lands of Orenburg serve as barriers to the encroachment of the I. W. W. element that has turned the revolution into a national collapse. At the same time these foreign companies appear to have conducted their operations in such a way as to have won the solid support of the local Russian managements, particularly of the technical staffs, so that, in the crisis of their fate, they were protected from harm. One cannot forbear admiring the good sense and sound policy responsible for this fortunate result. The chairmen presiding at the three meetings united in expressing confidence that the repudiation of contracts, expropriation of land, and anarchistic theories of the wild men at Petrograd will not be supported by the peoples of Siberia—the Kirghiz, Bashkir, and Cossack—and that before long the government of Russia will pass into sane and capable hands.

Copper Prices

It is claimed, at Boston, that the advance in the cost of the labor and supplies used in copper mining has increased the cost of producing the metal $1\frac{1}{2}$ cents per pound during the last four months, and that therefore the War Industries Board would have been justified in advancing the price to 25 cents. It is estimated, again among speculators in copper shares at Boston, that between 50 and 75 million pounds of copper per annum "is being produced today by mines which cannot do more than break even at $23\frac{1}{2}$ cents." Nevertheless, as our New York correspondent remarked, the argument for an advance to 25 cents was injured by the record-breaking production of copper last year in the face of an official price of $23\frac{1}{2}$ cents. Assuredly the price should be fixed at a figure that will encourage the production of all the copper required for the purpose of the War, besides that which is required for domestic consumption of an essential kind. Speaking of the price of copper, the average of the averages given weekly on our market page during 1917 was 27.52 cents. The 'Engineering & Mining Journal' makes it 27.18. The 'American Metal Market' places it at $29.26\frac{1}{2}$. We have good reason to believe that our average is nearly correct, as nearly correct as any calculation in which all the factors are not known and cannot be known. Our contemporary at New York poses as the last word in this matter, and has succeeded in persuading many copper dealers, particularly the buyers, that its guess is inspired. Nobody living is able to obtain a record of all the sales, giving quantity and price, and therefore nobody is able to give an accurate average. Even if the quantities and prices of all copper sales were known, as they never are, the average deduced therefrom would be incorrect, because the metal may be sold for spot, early, or late delivery, that is, the completion of the sale may take place at once or months hence. Sometimes, when the metal is scarce and prices are rising, there is no 'spot' copper available; at other times the supply is so good that forward sales are rela-

tively unimportant. The natural operation of the laws of supply and demand is checked or obscured by speculators, whose dealings are not known to the statisticians. Different producers obtain different prices for copper of the same quality, for we refer to electrolytic only. For instance, the Phelps-Dodge Corporation received an average of 16.05 cents per pound for its copper in 1915, as against the 'Engineering & Mining Journal' average that year of 17.27, a difference of 1.22 cents per pound. In 1916, the Nevada Consolidated averaged 25.83 cents for its copper, whereas the Utah Copper obtained 26.139 cents, and in the same year the Chino and Ray obtained 26.465 and 26.724 cents, respectively, for their copper. This suggests that the selling agency made a useful profit out of the Nevada Consolidated business. Why anybody should make settlement on the guess of an individual is not obvious, particularly when a surer basis of settlement is available. The miner employed by the Blank company allows his wages to be determined by the price of copper as guessed by an individual, by no means omniscient, at New York or Boston, when he could just as well take the price at which the copper of the Blank mine is actually sold, for sales are made usually 90 days in advance of production—sometimes 180 days in advance. He can take a fact, instead of a guess, as the basis of the calculation on which wages are determined. Similarly the mine-owner should drop the silly custom of settling with the smelter on the guess of any technical or trade paper; let him settle on the price that the smelter gets. Here again there is no difficulty, for the smelter sells its product at least 90 days in advance, and is able therefore to state exactly what price it is receiving. The time will come, we venture to predict, when these and other anomalies will be rectified. For example, we have received a copy of the report by the Smelter and Ore Sales Investigation Committee in Colorado. This committee was appointed by the State legislature to investigate "all matters connected with the purchase and sale and marketing of metalliferous ores," besides other subsidiary matters. Even the appointment of this committee had a salutary effect on the smelter trust, otherwise known as the American Smelting & Refining Company, which made several changes in its schedules by way of placating public sentiment. The existing schedules are needlessly complicated; they represent the efforts of the smelters to protect themselves under metallurgical and economic conditions that have changed from the time when the bases of settlement were first devised. The Committee came to the conclusion that "no schedule based upon the unit and quotation system will ever be satisfactory to the producer." It affords too many chances for hanky-panky. The Committee believed that the selection of umpire assayers by the smelters was open to objection, and suggested some system of licensing umpires. In the report will be found a number of interesting charts prepared by Mr. O. R. Whitaker, on whom the major portion of the work of inquiry devolved.

DISCUSSION

Heap-Leaching of Copper Sulphide Ore

The Editor:

Sir—I am writing you in reference to an article on this subject by Mr. Courtenay De Kalb in your issue of November 24, 1917.

Through a misunderstanding in writing the article the impression will be gathered that Mr. Irving is entirely responsible for the work being done, in fact it is expressly stated that "the details whereby the system is made adaptable to American conditions have been evolved by Joseph Irving, who is in charge of the operations at Bisbee." Mr. Irving is locally in charge of the part of this work now being done at Bisbee, but will not, I believe, make any such broad claim to the entire credit for the idea or for the evolving of the details to make it adaptable to American conditions, as might be inferred from the article. A. W. Hudson is in local charge of large-scale tests to be carried on at Tyrone, and in view of the above, I am perfectly willing, as is just, to share with Mr. Irving and Mr. Hudson, in view of their co-operation in this work, any credit due if these tests prove successful or the responsibility for the expenditure of considerable sums of money if the reverse prove true, but I feel justified in being unwilling to do more than share such credit or responsibility.

With apologies to your readers for any space devoted to the above purely personal matter, but which I think is due me, I would like to call attention to a few points in the article which I think require correction. A considerable part of the descriptive matter, and of the pictures and sketches in the article, refers to our Bisbee mine-water treating plant, which was in operation long before this kind of leaching treatment was considered, and which will be operated irrespective of the results of any leaching work done hereafter. The leaching experiments are connected with this plant only incidentally. The plant was not designed with a view to any leaching tests, and its main function has not been and is not now in connection with leaching but with the treatment of mine-water. Exception must be taken to the statement in the article that the process, as now conducted, has demonstrated a recovery of 80% of the copper in the ore at the costs given. The fact is that to date we have obtained a recovery of only about 27% of the total copper originally laid down. I feel that the results so far are sufficiently encouraging to hope for ultimate success, but I certainly do not feel warranted in saying that we have demonstrated either anything like a fairly com-

plete recovery or that our large-scale operating costs, if successful, will be those given. It is, of course, evident that, for either economy or even metallurgical success, in a matter of this sort, there must be careful experimental determination so far as possible of all the factors entering into the problem. These factors, as applied to Burro Mountain ore directly, and which will also be broadly applicable at Bisbee, are to be worked out by large-scale experiments which will be started in the near future at Tyrone. We anticipate several years before definite conclusions can be reached, owing to the unavoidably slow conditions of the tests, and do not feel that any definite statement as to construction, extraction, or costs can be made until the conclusion of these tests. On page 750 of Mr. De Kalb's article he states "experiments in precipitation were conducted on the mine-water for a period of nearly three years before 'heap-leaching' was tried. The possibility of economically reducing the ferric to ferrous salts by the use of Mr. Irving's pyrite filter was thus proved, and this paved the way for successfully treating the low-grade sulphides developed by drilling the disseminated granite porphyry ore on Sacramento hill." As a matter of fact this mine-water treating plant was in no sense experimental in character, but simply replaced the old and inconveniently located mine-water precipitation plant, which had been operated for years. Mr. Irving is entitled to credit for the actual installation of a pyrite-filter in connection with the treatment of this mine-water, but this pyrite-filter treatment was of course well known to every one familiar with leaching, and in no sense did its use "pave the way for successfully treating" these ores. As a matter of fact, it is now used only for the treatment of mine-water, and it is not now nor has it been used for the treatment of liquors from the heap. The statement made that this filter provides acid which maintains a 'sweet' condition of liquor in the precipitating-tanks is, I think, an assumption based on one of the equations that may be written to explain the reaction. These are extremely complicated, and very few of them have been definitely proved, and as a matter of fact I believe it will be difficult to show that the effective acidity will be any different for liquor after passing the filter than before. Under the proper conditions its use is of course well known to be advantageous, but I do not think we know enough of the chemistry of its action to say certainly what the reason for any favorable action is or to be able to write one equation which represents this action. As stated above, a distinction should be made between that part of

Mr. De Kalb's article describing the Bisbee mine-water treating plant and the leaching tests. Naturally this treating plant designed for quite another purpose will materially differ from that to be finally adopted if the experiments are successful. The description in the article of the work of the plant gives a good idea of this as it is, but the liquor from the heaps is not kept separate and therefore, since the mine-water is by far the greatest bulk treated, it will not be safe to apply the results from this without further tests to the design of a precipitating plant for liquor and conditions of an entirely different character. There are a great many inter-related factors which we have not yet made sure of: strength of solution in both ferrous and ferric iron, the effects of acidity, and of other possible constituents of the liquors, the depth of heap, the method of watering, interval for drying, size of ore, method of piling and of the making of foundation, of drains, and of water-proofing, all of which together with others will have to be worked out separately and in their relation to each other before a plant for this sort of treatment can be laid out with any degree of assurance of success.

The principal factor which we are now not sure of is the resistance of the ore to disintegration. If the ore crumbles by the action of the method to a slime, or even if any considerable part of it does, then percolation of the heap by solution and the solution of the copper will be so retarded that the method probably cannot be worked out for any practical depth of heap. It is only necessary to figure the amount of ground-space needed to treat eventually any considerable tonnage coming forward each day to see that the depth of heap and the possible thickness through which percolation can be done for a period of probably three or four years constitute the main deciding factors for or against the method. Many of the above factors evidently will have a bearing on the matter, and it is to settle as far as possible, systematically and thoroughly, the problems involved, that experimental work is to be carried on at Tyrone, which is to be under the local charge of Mr. Hudson, his former head-assistant in the leaching work at Douglas.

It is, I think, also safe to say that unless a method of precipitation can be devised that will do away with the very considerable labor charge for this operation it will be doubtful if the method can be applied to as low-grade ores as desired. Roughly speaking, copper from the cementation plant at Bisbee in the past has cost something like 2c. for iron and 2c. for labor, although, under exceptionally favorable circumstances, this has at times been reduced to nearly 3c. total. This is not an average, however, and it is safe to say that the average precipitation-cost for iron and labor under good conditions of the cement-copper plant treating mine-water has not been less than 4 cents. It is evident therefore that one of the main objects of the experimental work at Tyrone is to determine the utmost possible reduction of this precipitation cost. It should also be noted that the treating plant described in the article is designed for the accommodation of scrap-iron of various kinds, to-

gether with tin-cans. Assuming that the final experiments show that the method can be expected to be successful, it is only necessary to figure the amount of heaps, meaning the daily addition and removal of, say, 2500 or more tons of ore to see that scrap-iron is utterly out of the question as a precipitating material. Accordingly the questions of what kind and form of iron shall be used, its commercial availability, source, and relative economy become important problems. In other words, looking at the matter superficially, it appears to be an extremely simple proposition to put some ore in a pile, pump some water over it, and precipitate the resulting copper on iron. As soon as it is studied, however, it is evident that, for any commercial scale, it is a complicated chemical and engineering problem of quite the first rank. I do not therefore think it is safe to say, as the article states, that, in the new plant that will be built to handle the solutions from heap-leaching on a large scale when treating the Sacramento Hill low-grade ores, the vats described will entirely supersede the launder system. In the first place we are not at all sure that such a plant will be built, and in the second place we have certainly not enough data at present to make even a guess as to the design of the precipitating system, but we are quite sure that the problem will be radically different as to possible labor costs, the precipitant, and the liquors to be treated from the present practice at Bisbee.

Regarding the precipitating vats: the adapting of the Dorr mechanism to such vats being considered an improvement will, I think, be at present a matter of opinion to be decided later in view of their performance. Regarding the chemistry of the process, this is complicated, and I do not feel personally that we have sufficient knowledge from experiment to warrant our considering that the equations given represent the facts. To some extent this is a matter of opinion, but I think it can be shown that some of them at least will not occur under the conditions of our process. We are on somewhat more solid ground in considering the equations which the article states are offered by Mr. Irving as representative of the reactions that take place in the ore-heap, since these are more or less the accepted ideas in regard to the reactions taking place in the Rio Tinto heaps. Whether or not they will be found to be those which will also take place under our new and radically different conditions I do not feel competent to say now and therefore can agree fully with Mr. De Kalb in his statement that the last word has not yet been written. Mr. De Kalb states that "it has not been definitely ascertained what proportion of the copper in the leach-tailing, which contains about 20% of the original copper, is in the form of metallics. It would be an interesting inquiry, since it is difficult to believe that any considerable amount of sulphide could escape the action of the solution after a year of treatment under conditions carefully maintained to secure the highest possible degree of oxidation." We have no leach-tailing containing 20% of the original copper, since as stated the leaching has so far only progressed to the extent of extracting 27% of the

copper to date in about eight months. Based on Rio Tinto practice we have assumed (and this is pure assumption) that the time required for treatment to a possible 80% extraction will be from three to four years. It is encouraging to note that, when we plot the curve against time of our actual extractions to date, it so far lies almost exactly on the line of our assumed time, but, of course, we have no safe way of extrapolating this curve, and I personally would be much surprised if more than 30 to 40% of the sulphides present will be acted on at the end of a year's work. The reactions are very slow at the best, and they cannot, in the nature of the problem, be maintained so as to give the highest possible degree of oxidation. It is quite evident, if we consider a single good-sized lump of ore, say, six inches or more in diameter, that either this will disintegrate or not. If it does not disintegrate then the leaching solutions must follow into the lump the practically microscopic channels through which the secondary sulphides were deposited. If disintegration takes place so that the process of penetration takes place more rapidly, then we are confronted by the above mentioned mechanical troubles.

A few more words regarding the description of the actual heap and its operation on page 756 of Mr. De Kalb's article will finish what I have at present to say on the subject. "No special preparation of the ground was attempted." This is a fact, but the preparation of the ground as a site for the piles forms one of the larger problems we have to investigate in our Tyrone work. "A vertical depth greater than 25 ft. is inadmissible owing to the danger of channeling." This is at present purely a matter of opinion and the depth will naturally differ with the character of the ore, the kind and strength of solutions, and the method of treatment. I am not now in a position to say that any particular height is either inadmissible or possible. Too shallow a pile is impracticable on account of the enormous space needed for any considerable production. Naturally the depth of pile is to be tested out thoroughly during our Tyrone work, but we cannot say now that we know anything about what depth of pile can be finally adopted. It should, I think, be emphasized, in criticizing this article, that the results so far are purely preliminary, and while they are encouraging they may or may not lead to ultimate commercial adoption of the method for our conditions.

G. D. VAN ARSDALE.

New York, January 17.

[Mr. Van Arsdale is welcome to the space taken by his criticism, which is interesting. We think it best that Mr. De Kalb should not reply, thereby avoiding an undesirable controversy. Of course, we regret if inadvertently Mr. Van Arsdale has been given insufficient credit, and Mr. De Kalb shares this regret. In regard to the chemistry of copper-leaching, we are well aware that many of the reactions are obscure, but that is no reason for not trying to clarify them. Mr. Van Arsdale's opinion con-

cerning them would be interesting, as interesting as those of Mr. De Kalb. Meanwhile our readers will be more grateful to the metallurgist that discusses them than to those that prefer to remain silent in the expectation of saying the last word concerning the process. That they will never do, for we all die learning.—EDITOR.]

Patents and Royalties

The Editor:

Sir—You may perhaps remember that about a couple of years ago, I entered upon a little campaign to obtain some pecuniary recognition from users of Pachuea tanks in this country. I think, at the time, you wrote a paragraph in the PRESS, calling attention to my method of collecting royalty. Now, it will probably interest you to learn the result of this campaign.

When I was considering taking this action, I spoke to several friends, and most were of the opinion that I would not even receive an answer to a letter that did not have a legal threat behind it; but I have considerable faith in the good side of human nature and was not discouraged. As a boy, I was thrown upon my own resources in these Western States and I have always found that fairness begets fairness, and I am not afraid to trust my fellow-man. When I had drafted a letter I showed it to a legal friend, and he shrugged his shoulders and remarked that it was very frank. Perhaps his legal training had produced in him this caution. The letter went forth, and, after waiting several months, I was almost forced to conclude that my cold-blooded business friends were correct; but I still cherished my hope in the fairness of true business-men. My patience was rewarded by receiving a letter from the manager of one of the large mines, briefly stating that he had been absent, and that my proposition seemed a fair one, and that he was pleased to pay on the tanks his company was using, at the rate set forth in my letter. I have not had the pleasure of meeting this gentleman, but have inquired about him from men who know him, and find he is one of those big men who has been found faithful in small things and is now entrusted with great things.

By this time practically all the real mines, or shall I say real managers, have paid the small recognition I asked, and from the letters I received it is easy to see that my appeal to fairness struck the chord that produced results. If I had relied on the legal stick there would have been 'nothing doing,' as I am afraid my temperament has not enough of the bulldog in it to bring a legal tussle to a successful issue.

It is a pity that fairness, which is inherent in all men, is not more used in our labor questions. Some years ago I had about twelve months experience noting the evidence given in the Arbitration Court in connection with a big labor dispute, and I came to the conclusion that, if it were only possible to get the men on each side together, fairness will accomplish more than all the legal argument that can be brought to bear on the question.

There were, of course, some mines that did not reply

to my letter, and as time went on, I was able to size up the management, by making inquiries from machinery agents and others I come in touch with. It is the old story, that a man who has not the courtesy or self-reliance to reply to a letter, is 'small.' Some users pleaded that the mine was not paying, and I am only too pleased to let the matter rest at that, and to hope that they will strike good ore.

[This letter was not intended for publication, but we wrote to Mr. Brown and obtained his permission to reproduce it in these columns.—EDITOR.]

Nickel-Copper Steel

The Editor:

Sir—I have noted with much interest the timely article on nickel-copper steel direct from the Sudbury ores, written by F. H. Mason and appearing on page 57 of your issue of January 12.

I would like to correct one statement made in this article, in which it is stated that Prof. Stansfield repeated Sjöstedt's experiments at the request of the Royal Ontario Nickel Commission. Mr. Stansfield, on the contrary, made his experiments at my request, and at my expense, and along the lines of the process which I had patented and which is now known as the 'Nieu steel' process, the rights having been sold by me to the Nieu Steel Corporation, Ltd. You will note in the report of the Ontario Nickel Commission that Stansfield experimented with a patented process. This is the process referred to, and I turned his report over bodily to the Nickel Commission, having secured it with the idea of obtaining corroborative evidence as to the success of the process from a high-class independent metallurgist. I believe that the Royal Ontario Nickel Commission afterward asked Mr. Stansfield to write a general article stating his opinion of the various methods of treating the Sudbury ores and his opinion concerning the qualities of nickel-copper steel. This also appears in the appendix to the Commission's report.

In reference to the criticism that is made concerning my estimate of the cost of producing nickel-copper steel, this seems entirely justified, since two tons of ore will not produce one ton of pig-metal; it actually takes about $2\frac{1}{2}$ tons, but in practice we have always mixed the Sudbury ore with a certain amount of steel or iron scrap, or iron ore, and the cost of this material I did take into account in estimating the actual cost of smelting. For example, in smelting the ore in an electric furnace, we had to use a considerable amount of steel filings in order to make a contact and this supplied the deficient iron to make up the ton of pig.

You may be interested to know that the Nieu steel process has actually been put into commercial operation at East Montreal in the month of October 1917, and about 90 tons of steel was made by this process, and some

of it is entering into actual commercial use, while test-pieces are being examined by various war-boards and commissions in the United States and Canada. The manufacture had to be discontinued because it was impossible to rent the furnaces for a longer period than the one month, but we are now negotiating for the continued lease of a steel plant and hope to arrange to manufacture the steel continuously, even if only on a small scale.

In actual practice we reduced the roasted ore in an electric furnace and refined the pig first in an electric furnace, but afterward, and with much better success, in an open-hearth furnace. We believe that eventually we shall be able to carry on the process along the lines of regular steel manufacture, reducing the roasted ore in a blast-furnace and refining in an open hearth. This, of course, will enable us to manufacture the steel at a considerably lower cost than could be effected by the use of electric furnaces.

Humboldt, Arizona, January 15.

Native Iron Reduced by Oil

The Editor:

Sir—The editorial in your issue of December 29, in which you facetiously remark that "As far as we know, no vein or other natural deposits of brass or even 'steal' have been discovered in Arizona or in any other of our rich and varied mineral regions," brought to my recollection an inquiry which I had from a correspondent, about three years ago. His letter says, "I am interested in a prospect down near the coast, on which we are boring for oil. We have had very great difficulty in breaking through a stratum that lies 1635 ft. below the surface. It took us two or three days before we could begin to make an impression, and then we only went through two or three inches per day, until we went through 18 in. of the material." I found the sample which he enclosed in his letter to be metallic iron, in grains of a slightly spongy character. In a subsequent letter he informed me that they had found oil underneath, although not in sufficient quantity to be of commercial value. I had already informed him that this would probably be the case, for it is apparent that a bed of hematite had overlain the oil and had become reduced to that metal through the action of heat. Although I have heard of large masses of metallic iron being found in Greenland, and in smaller quantity elsewhere, especially in dike-rocks, I had never previously heard of a deposit of the metal. As its appearance in that form appears to me to be unique, it would be interesting to hear if any of your readers have had a similar experience.

THOS. FRENCH.

Nelson, B. C., January 9.

EXPORTS of bituminous coal from the United States has increased from 16,083,101 tons in 1913 to 19,628,848 tons in 1917. The greatest increase was to Italy, the figures being 332,264 and 1,099,508 tons respectively.

RAILROAD STATION AND PLAZA, AJO, ARIZONA

Ajo Copper Mine—II

By COURTENAY DE KALB

EXPLORATION. The Ajo deposit was developed by diamond-drilling, done by the E. J. Longyear Co., of Minneapolis, on contract. The diameter of core at the beginning was $1\frac{1}{8}$ in., and was the same at the bottom of the holes. The average depth of the holes was 300 ft., and in the centre of the deposit they extended to a depth of 1000 ft. The rods were pulled every 5 ft. and core-samples taken. The total sludge from each 5-ft. section was also collected in barrels and settled. The water was decanted, the whole of the sludge being dried and quartered down to a sample of about four pounds for assay. The entire area was surveyed into blocks 200 ft. square, and a drill-hole was sunk at each corner. Mr. Joralemon states that, "Owing to the thoroughly fractured uneven nature of the rock, the recovery of core was low, and neither core nor sludge-samples alone were satisfactory. To obtain an accurate assay-value for the ore developed, the length of core for every 5-ft. advance was measured, and on the basis of this length of core the sludge and core-assays were combined to give a final value, which represented all the material removed from the hole during the 5-ft. advance." After developing with drills for a period of six months the results were checked by test-pits 4 by 6 ft., sunk with the aid of windlasses. This work was done by Mexican and Indian labor. Every tenth bucket windlassed from the pits was taken as a sample. After the pits were completed they were again sampled in 5-ft. sections by channeling. Eighty-four diamond-drill holes were sunk; they ranged from 200 to 1000 ft. in length, aggregating 23,097 ft. of hole. These were checked by 77 test-pits, amounting in all to 3955 ft., of which 3600 ft. was in carbonate ore. In addition to this the sulphide ore was explored by 1513 ft. of drifts. The estimate based on the data obtained in this way was as follows: 11,954,400 tons of carbonate ore assaying

1.54% copper, and 28,303,600 tons of sulphide ore assaying 1.50%. Of this amount 32,481,200 tons was available by steam-shovel mining, leaving only 7,776,800 tons of sulphide ore, of an average copper content of 1.40%. The unoxidized orebody will be removed ultimately by caving. The central part of the deposit is available without the necessity of stripping overburden, since the copper extends in undiminished quantity to the very surface. Around the edges, however, are patches of overlying rock that represent a total of 3,308,000 tons that must be stripped. This overburden assays above 0.63% copper, and is not necessarily waste. As Dr. Ricketts once said to me while looking over the vast tailing-pile at Cananea, "The stuff is useless for anything today except to serve as a fairly good dam for our settling-pond, but some wise metallurgist in future will extract the copper from it; the waste of this generation is the wealth of the next."

As soon as this exploration and development had been completed, the New Cornelia Copper Co. was organized with a capital stock of 1,200,000 shares of \$5 par each, the capital being increased later to 1,600,000 shares, of which 1,201,600 were issued. An issue of \$4,000,000 of 6% mortgage convertible bonds was authorized also, and the Calumet & Arizona Mining Co. subscribed to \$3,100,000 of these at par. When the 'C. & A.' was listed on the New York Stock Exchange the circular issued to the public stated that the holdings were 90 patented claims aggregating 1629 acres, with 15 mill-site claims comprising 74.94 acres, and that the property drilled had shown 40,000,000 tons of ore having an average copper content of 1.51%; it also declared that the average monthly production would be 3,000,000 lb. of copper. This has now been completely realized, although the plant has barely passed the point of 'tuning up.' Oper-

ations started as recently as May 1917, and the necessary changes are not yet complete. In August the output was 2,200,000 lb. of cathode copper; and in October it had been brought up to 3,260,000 pounds.

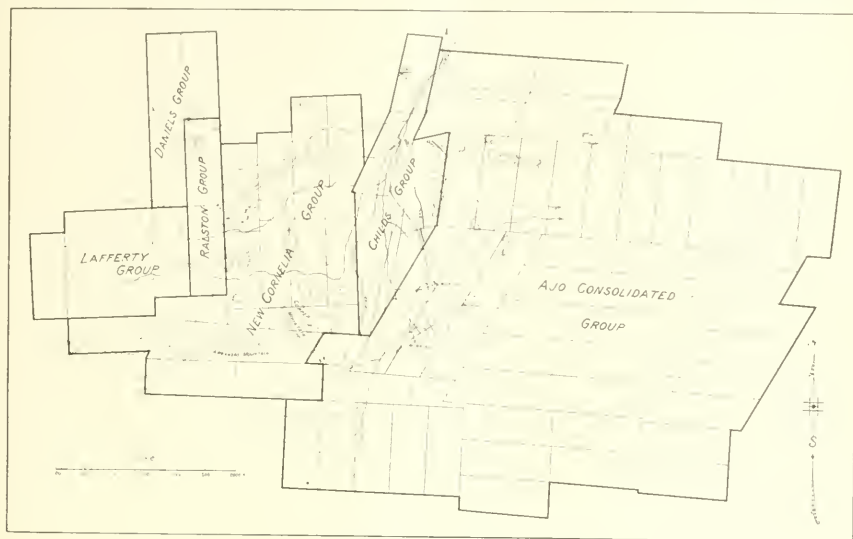

On July 28, 1917, the board of directors issued a call to the stockholders for proxies, authorizing an important move for expansion. It was announced that the production in June had been 1,093,000 lb. of copper from the leaching-plant, and 225,876 lb. from ores shipped to the smelter at Douglas. The opinion was expressed that "there will not be any material difficulty in maintaining a recovery of at least 80% of the copper content of the ore." Then follows the statement that the opportunity had presented itself for adding to the ore-reserves of the company by the purchase of 7 patented and 52 unpatented mining claims, amounting to 1150 acres, covering an extension of the orebodies already owned. The circular set forth: "Part of this new ground has been explored by the former owners by 5500 ft. of drifts and raises, and by drilling, and the estimate of tonnage of ore in the explored part is 21,000,000 tons, averaging 1.55% copper. The character of these ores is identical with our old ores, the major portion being sulphides. We have not been able to check fully all the work, but have checked important parts by new drill-holes, and have examined the records and made numerous assays of samples furnished from the drillings, all of which were done by the same reliable contractor who drilled our old territory, so that we feel entirely satisfied of the value of the property to the New Cornelia Copper Co." The terms of the purchase were to deliver to the owners of the Ajo Consolidated Copper Co. 200,000 shares of New Cornelia stock, and notes of the company for \$500,000 due in 6 and 12 months, respectively, with interest at 4%. The apparently simple ease with which a development company was able to convince a great corporation, mainly with its own development records and samples, and to obtain so large a sum in notes and gilt-edged securities, for a mine that represented a total capital expenditure of probably \$700,000, finds explanation in a number of circumstances. The circular gives one of them: the same drilling-contractors had done the work, and their reliability had been demonstrated previously to the New Cornelia Copper Co. The employment of the same contractors that had served the one logical buyer of the mine displayed good business judgment. In the next place, the New Cornelia Copper Co. had finished its campaign of development, and had worked out the essential geological relationships before serious exploration on the extension was undertaken; in other words, the New Cornelia company had shown the reasonableness of expecting ore in a direction that if known in 1911 would have enabled them to avail themselves of a proffered option on this area at a price of only \$300,000. Finally, the owners of the Ajo Consolidated Copper Co., namely, James Phillips Jr. and associates, placed the control of their development campaign in the hands of a capable manager, James P. Gaskill, in whom the heads of the New Cornelia Copper Co. had confidence as an engineer

and as a man of integrity. To meet the requirements of this purchase the New Cornelia company increased its capital stock to 1,800,000 shares. It may seem that the directors paid heavily for what some might deem lack of foresight, but the argument will not hold. To be sure, money would have been saved by accepting the earlier opportunity, but a considerable amount of spot-cash was demanded by the original owners at that time, and this would have increased the initial outlay at a moment when the entire project rested on hope, restrained by the discouragement of previous investigators. The argument, in fact, might be turned the other way: the old Ajo Copper Co. which later sold its interests, together with such rights as had been held by the Rendall Ore Reduction Co., to James Phillips and his associates, who then organized the Ajo Consolidated Copper Co., might have obtained a larger sum in the end by offering the property to the New Cornelia on such liberal terms as would have postponed all payments until the first nut had been cracked. Until the faith of Capt. Greenway, Dr. Ricketts, and their comrades, had been vindicated by the drill on Copper mountain, it was wise to defer expenditures looking toward expansion; equally was it a matter of sound business policy to take over the property after their own development and that of their rational neighbors had shown that a reserve of 520,800,000 net pounds of copper, together with an area offering possibilities of many times the amount by further development, could be purchased for 0.29¢. per pound of net recoverable copper on a basis that, as the circular stated, "need not defer the time when payment of dividends can be commenced."

THE MINING OPERATIONS are relatively simple. A standard-gauge service-track 4000 ft. long extends from the level of the upper floor of the crusher-house to Copper mountain. It enters the orebody through a cut, and divides into two tracks, serving steam-shovels on each side of a great open-cut across the mass of carbonate ore. The width of the open-cut is over 200 ft., and the maximum height of face against which the steam-shovels are advancing is 125 ft. The cut is about 2000 ft. long, and as it widens it will take an irregular slice over 66 acres; 750,000 tons have already been excavated and sent to the metallurgical plant. The mining is under the superintendence of Fred R. Eckman, a man trained to efficiency in the hard but expansive school of the Lake Superior iron mines, in which the American practice of mining 'in the large' chiefly has been developed. The accompanying sketch illustrates the manner of attack. Near the bottom is drilled a series of holes to serve as 'lifters,' each 45 ft. deep, and inclined at an angle of 22° from the horizontal. Next comes a series drilled on a bench about 75 ft. above the bottom, bearing into the wall. These holes are 30 ft. deep and break to a lower bench above the lifters. A third series is drilled vertically to a depth of 32 ft., and 18 ft. back from the edge of the ore-face. The holes in each series average about 18 ft. apart horizontally. Ingersoll-Rand air-drills are used, taking air at about 70 lb. pressure, and 3½-in. drill-steel is employed for start-

ing the hole, drawing down to $1\frac{1}{2}$ in. at the end. The hole is then sprung with 40% dynamite, this being repeated twice, and consuming $1\frac{1}{2}$ boxes of powder. The chamber is then loaded with four cases of 25% dynamite. This

rock has resulted in an excess of large masses over the amount originally estimated, and the labor-shortage makes it difficult to obtain a sufficient force of drillers. Therefore, the full quota of 5000 tons of ore daily is at

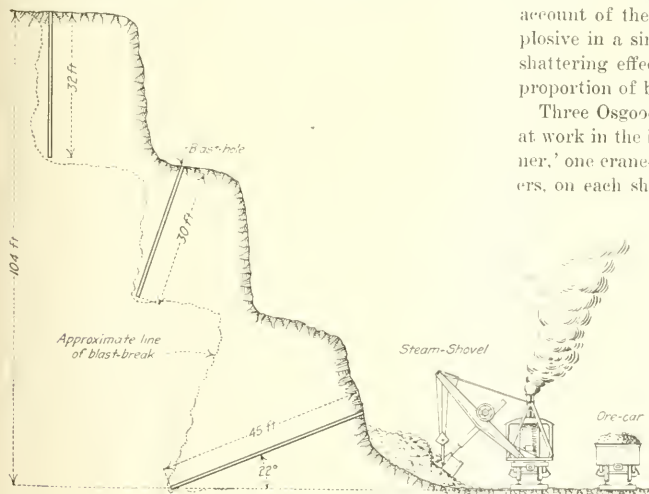

MAP OF CLAIM GROUPS AT THE AJO MINES

is now being replaced to a considerable extent with black powder. For each pound of total powder used four tons of ore are broken. The larger masses are block-holed, employing jack-hammers. The block-holing would not

present difficult to deliver to the crushing-plant. It is proposed to drill holes on the high banks in future with Cyclone churn-drills, set about 15 ft. back from the edge in which charges of Trojan powder will be fired. On account of the concentration of a large quantity of explosive in a single charge, it is expected that a superior shattering effect will be obtained, thereby reducing the proportion of block-holing to the total tonnage broken.

Three Osgood steam-shovels, with 4-cu. yd. shovels are at work in the big open-cut. A crew consists of one 'runner,' one crane-man, one fireman, and four Mexican helpers, on each shift. Four trains of 8-ton side-dump cars are constantly in service hauling the ore to the crusher-house.

At the south-west end of Copper mountain underground work is in progress along the contact between the monzonite and the rhyolite, under the charge of George Harmon. A shaft has been sunk 60 ft. deep, and a drift extended under the mineralized rhyolite, which at this point averages about 4% in copper that is present as minutely disseminated silicate and carbonate. The ore is broken around an open pit and drawn to the loading-chute through a mill-hole in the bottom of the funnel-shaped opening. It is estimated that 81% of the Copper mountain orebody is available for mining by steam-shovel, but this will involve working downward below the level of the ore-railroad by spiral benches.

METHOD OF BLASTING HIGH BANKS

seem to be a serious matter, since the No. 24 gyratories in the crusher-house will take pieces of ore 8 ft. long by 4 ft. in the other two dimensions, and the steam-shovels will load blocks of that size; but the character of the

The ground rises from the site of the metallurgical works, so that drainage of the pit will be easy to a depth at which open-cast work will cease. The mine is ideally situated for economical operation, and presents no difficult engineering problems so far as the original New Cornelia area is concerned. The extension of the deposit under the rhyolite, however, will call for the adaptation of caving methods to fit the special conditions there presented.

The building of a branch railroad was a necessity for the operation of a property that was to start with the treatment of 5000 tons of ore per diem. Surveys were made at first directly west from Tucson, a distance of 135 miles, passing through a region containing undeveloped agricultural resources, and many copper prospects in the Coyote, Comobabi, and Quijotoa ranges, where important developments have taken place. This would have afforded a route connecting at Tucson with the El Paso & Southwestern railway and leading to the smelters at Douglas. The alternative was to build over open plains between the scattered basin-ranges 43 miles northward to Gila Bend, a station on the Southern Pacific railway. This involved the least initial expenditure, which was important in view of the outlay of \$4,000,000 needed for erecting a metallurgical plant. The railroad cost \$700,000, and is operated under an independent organization styled the Tucson, New Cornelia & Gila Bend Railway Co., of which one-half the capital is held by the Calumet & Arizona Mining Co. In the title lies a suggestion of the ultimate construction of the line through to Tucson, which would appear logical.

AN IMPRESSION. The approach to Ajo is over a typical Arizonan desert-plains depressed between surrounding ranges in the form of vast basins, overgrown with creosote in the lower portions, and adding bayoneted yuccas and opuntia cacti toward the heads of the clino-plains. The color of the landscape in the broad perspective is green, suggestive of an abundance of verdure, which, however, is not confirmed by the barren ground near at hand over which the creosote bushes are seen to grow far apart in a kind of distant association with each other. The mountains are mostly gray, except where remnants of the basaltic lava-flows form black frowning mantles over the older rocks. At one place a great fault has involved the underlying formation as well as its lofty burden of lava, and along the fractured zone is a broad band of iron-stained outcrop that makes a brilliant display. These lavas once covered the Ajo ore deposit, and a few iron-stained fragments still endure on its higher points. Erosion swept the cap of lava away until the ore was left exposed to the sun. The purplish peaks of altered rhyolite are visible from the train, rising behind the brown hillocks of ore, while toward the north swings the grayish lavender range constituting the extension of the grano-dioritic mass of which the orebody is in a favored differentiate. The town and the works spread around the entrance to the amphitheatre, in the centre of which is Copper mountain. The place looks like a city, and so indeed it is, built at the command of

the copper barons with the magic of money, industrial purpose, and proved resources. The train halts in front of a station of unexpected beauty. No suggestion of what the West calls a mining 'camp' was here; it was like coming to a fashionable resort for tourists. The sky was of Algerian brilliancy, and the air was soft and exhilarating. The beautiful double colonnade and Moorish towers of the station aided the delusion of being in northern Africa. The richly-colored arches extended for the distance of a city-block on either side of what one hesitates to call a 'ticket-office' when surrounded by so much aesthetic charm. Through the arches was a vista of a deep-green plaza, the carefully tended lawn rising gently toward a low tower surrounded and almost concealed by flaming oleanders; and along the other side of this remarkable plaza, which would make the cities of San Antonio or San Diego envious, is a continuation of Moorish structures and broad colonnades. It presently appears that here is concentrated the activity of the town. It is a civic centre in an unusually real and delightful sense; at the Plaza is found the post-office, and the offices of the local civil authorities, the stores, cafés, and chocolate-shops, the 'movies,' and all that makes up the round of business and pleasure of the community. Whatever one may need, just as in a Spanish city, he will find at the Plaza! There is where people meet, where they find refreshment, and listen to the band in the limpid Arizona nights while the children romp upon the electric-lighted green, for in some way, which means with the aid of a generous purse, the New Cornelia Copper Co. has found it possible to dispense with the customary disheartening injunction to "keep off the grass." In a spirit of delightful democracy the children of the staff and of the laborers mingle in their play for a while under influences that make for a better understanding between them all. It was a costly bit of luxury for a mining company to offer all this before it had begun to make a profit from its enterprise, and the vision to undertake such extraordinary welfare-work is credited to a member of the directorate, a man of fine feeling and generous sympathies, now mourned as one lost from the council-table, the late Chester A. Congdon. It was a practical thing to do, for it meant relief from the ugliness and despair of the customary 'mining camp' with its glare of barren clay and sand, its piles of rusting tin-cans, and its spiritual vacuity; it meant refreshment, reinvigoration of body and mind, and the conservation of self-respect through respectable and cheering surroundings. Thus it has proved as good an investment as some of the new mills, and lead-lined pumps, and other accessories introduced to help in the mining of ore for profit.

OTTAWA, Canada, now claims the largest gold refinery in the world. The Ottawa mint was recently enlarged, and is now capable of treating 250,000 oz. per week by a chlorine process. Since the beginning of the War Canada has handled one billion dollars' worth of bullion for the British government and the Bank of England.

Controlling Fires at the Copper Queen Mine

By GERALD SHERMAN

*Mine-fires are always dangerous and are frequently accompanied by loss of life during the period of confusion that is apt to follow their discovery. In metal mines, fires may result from the accidental ignition of some combustible material, or they may be of spontaneous origin resulting from the rapid decomposition of sulphide. They occur frequently enough to demonstrate the need of some special equipment and a general plan for controlling them, in addition to measures for their prevention. Nearly all the large copper mines have had fires, and the methods of fighting them have been well described in recent papers, notably by C. L. Berrien,¹ R. E. Tally,² and others in discussion.

The Copper Queen mine has many shafts, which are connected by underground workings. The deeper parts are ventilated by fans, but in the shallower portions natural ventilation through numerous connecting raises or

shafts is sufficient. There have been several fires in the past few years, of which all are extinguished but one, and that is under control. These notes cover particularly the preparations that are being made to check

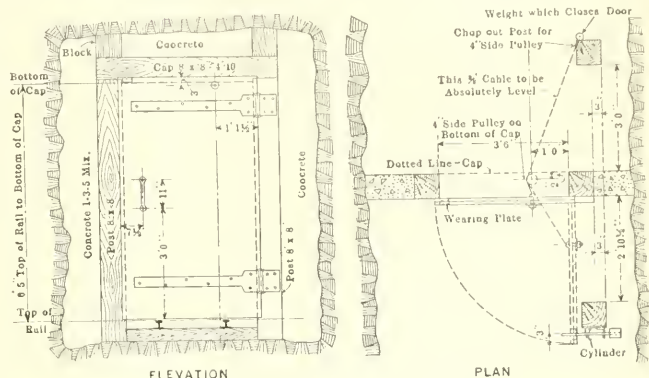

FIG. 1. METHOD OF MOUNTING FIRE-DOORS

a new fire, partly or temporarily, and to facilitate the escape of workmen in the interval before a definite plan of fighting it can be established.

A fire may occur in a shaft or station, or in some working farther away. In case of fire in an upcast shaft, the gas would escape to the surface and the immediate result would probably not be dangerous to workmen, as they could escape by other shafts. In a downcast shaft, however, the gas would be distributed rapidly throughout a large portion of the mine, and men might easily be trapped and asphyxiated. A fire in mine-workings, drift, raise, or stope, would be dangerous in a degree, but the draft there is likely to be less strong than in a shaft and probably a small area would be invaded by the fire-gases.

At the Copper Queen mine, in all drifts connecting with individual shafts, systems of doors are now being constructed that may be closed at any moment, cutting off the circulation of air as completely as possible, so as to check or stop the draft. Thus, in case of fire in any shaft, the doors in all drifts communicating with the shaft can be shut immediately and simultaneously, and water can then be turned on through a sprinkling system to put out the fire, if possible. In case of fire in interior workings, the doors of one or more shafts connecting with the section affected will be closed at once, thus isolating the fire-district and protecting exits from the mine as well as checking the progress of the fire. In a way, these doors will serve a purpose similar to the

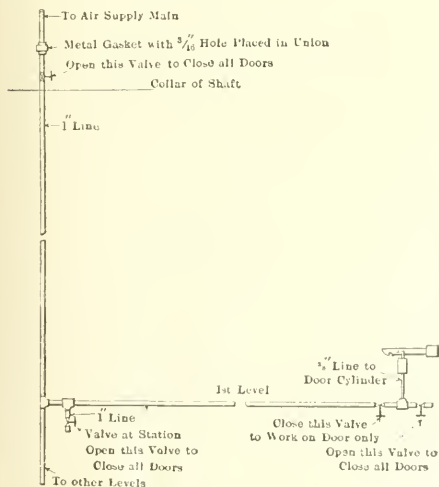

FIG. 2. PIPE-CONNECTIONS FOR OPERATING DOORS

*A paper to be read before the American Institute of Mining Engineers at the New York meeting, February 1918.

collision-bulkheads in a ship. Several shafts are already equipped in this manner and all will be, as soon as possible.

A sketch of the doors is given in Fig. 1, and a diagram

FIG. 3. DETAIL OF LATCH MECHANISM

of the piping system through which they are operated is shown in Fig. 2. Fig. 3 gives details of the operating mechanism. The doors are set in concrete, and are normally held open by a latch; when the latch is thrown, the door is closed by a weight. The latch is held closed by an air-cylinder acting against a counterweight. The air-cylinders connect by piping with all doors protecting the shaft and with the compressed-air main on the surface. By opening a valve at any station, or at the surface, the air system is drained of air, the pressure on the cylinder falls, the weight throws the latch, and allows the doors to close. Any door, of course, may be opened by hand afterward. A small hole in a metal gasket furnishes enough air to supply leakage in the pipe system but not enough to prevent the fall in pressure when any valve is opened. By this arrangement, if anything goes wrong with the piping or air-pressure, the doors close automatically; if the latches were thrown by cylinder-pressure, instead of the reverse, they would fail in case of accident to the air-line or its injury by the heat of a fire not quickly discovered. It is probable that the doors cannot be made air-tight, but if necessary they can be easily and quickly caulked by helmet-men after they are closed.

The arrangement would be of benefit whether the shaft be down or upcast. In case of an upcast shaft, the result would be the checking of the fire because, without the doors, the draft would be increased by the fire. In case of a downcast shaft, it would largely prevent gas from passing into the mine.

After the doors are known to be closed, it will be safe to turn water into the shaft; but until they are closed, or until all men are known to be out of the dangerous part of the mine, it might be extremely dangerous to turn on water, as this would cause a downdraft, carrying gas and fire into the workings.

Pouring water into the top of a shaft does not seem to be effective in extinguishing a fire, as but a small proportion of it reaches the desired point. Pipe-lines therefore are laid down the shafts, to carry water to sprays set under the timbers at 25-ft. intervals and pointing down (Fig. 4). Uniform flow is obtained through all sprays by adjusting a service cock in the line connecting each spray with the shaft main. Water can be turned on only from the surface. By this means, a shaft can be saturated with water quickly and effectively, the only difficulty being that it may be necessary to delay turning on water until the fire has attained considerable headway, that may have damaged the shaft and pipe-line sufficiently to interfere with the distribution of water. Fusible plugs could be used in the sprays, but it is feared that spraying at the wrong time might endanger men in the mine. If the stations are timbered, it might

be advisable to have sprays with fusible plugs distributed in them.

As at present outlined, the general procedure in case of a fire would be:

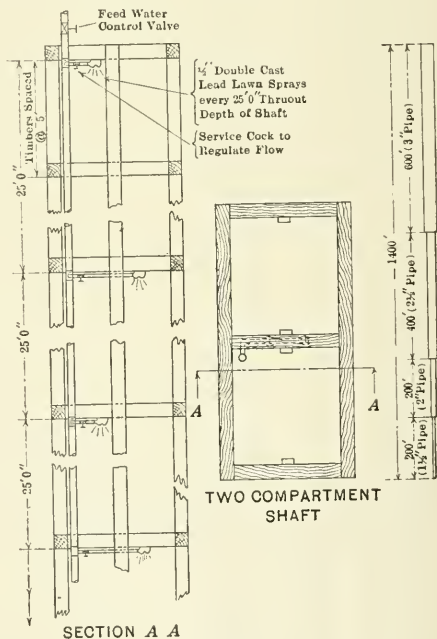

FIG. 4. CONNECTIONS FOR SPRAYING SHAFT

1. Giving a general fire-alarm, the district in which the fire occurs being indicated by flashing a number on all electric lights on the property.

2. Closing of doors communicating with the dangerous area, and shutting down the fans.
3. Getting workmen to the surface.
4. Turning on shaft sprays.
5. Development of a general plan for fighting the fire or controlling it within certain limits. Those ventilating fans that can be operated safely may be started.

In case of fire within the mine, shaft-spraying would be unnecessary unless the fire were so close that it would be desirable to saturate the timbers to prevent their igniting easily.

It is probable that, in the future, additional doors, which may be closed from the surface as well as from other points, will be placed at various places in the mine; this will divide the mine into sections with the expectation of isolating a fire, checking it somewhat, giving time for men to escape, and permitting a method of fighting to be established, as in shaft-fires.

It has been found that serious delays often occur in getting water to a fire, even though compressed-air piping can be connected with water mains and used for the water system. Experiments are now being conducted in the use of a chemical fire-engine that may be of assistance in certain cases. However, carbon dioxide from the engine is as dangerous as fire-gas, and it would not be safe for men without helmets to use the engine unless the carbon dioxide could be carried away by a positive draft.

A portable fan operated by a storage battery is kept in service; this can supply local ventilation to assist in getting at the fire.

Future of Electrolytic Zinc

*The average zinc recovery by the electrolytic method is less than 70% from ores or concentrates containing 40% Zn, but as 90% extraction has been reached the average recovery will increase when the causes for disparity have been found. By proper roasting, 90% extraction from ores of 15 to 25% Zn is not difficult to obtain. A Wedge furnace with seven hearths and 22 ft. diam. will roast $1\frac{1}{4}$ tons of ore per hour. After roasting zinc concentrate containing 45% Zn, 95 to 97% extraction is possible. No more experience is required for the electrolytic process than for the retort process. The electrolytic is as much dependent on cheap power as is the retort process on cheap fuel. Labor and power-costs for the retort process while roasting in a Wedge furnace is less costly than that in the special furnaces used for roasting the ore for retorting. An ore having the same lead and silver content, but with 25% Zn, will have an increase in cost of production of 0.05c. per lb. of zinc, but the zinc recovered pays for the ore and leaves a small profit, and the residue has been reduced one-half for the lead smelter. An aspect in favor of the electrolytic process is the presence of manganese as an essential pre-

ventive of sulphating or destruction of the anodes in the electrolytic vats. It purifies the electrolyte by decomposition on the anode as hydrated MnO_2 . In manganese-bearing zinc ores the manganese may be recovered for use in dry batteries. Solution of the zinc in the roasted ore is accomplished with very little loss of sulphuric acid through precipitation of basic iron sulphate, but since iron and lead deplete the solution of more sulphate than the $ZnSO_4$ furnishes, SO_2 from the roaster is brought into contact with MnO_2 , and $MnSO_4$ is formed from which MnO_2 is deposited electrolytically, while the H_2SO_4 is thereby added to the circuit.

France Using Cast-Iron Shells

France is making more than a million cast-iron shells per day, according to the competent testimony of Edgar A. Costa. In arguing for cast-iron as opposed to steel shells, Mr. Costa points to the superior effectiveness of the iron shells in attacking earth-works. He claims that the efficiency of a shell fired against troops is dependent almost entirely upon the character of its fragmentation. In this respect cast-iron shells have been demonstrated to be more satisfactory than forged steel projectiles. The former, also, can be made easily in enormous quantities, given proper foundry practice. France is making the large number of shells mentioned in dry-sand molds. A steel forging for a 4.7-in. shell costs over \$7; a cast-iron shell of similar size can be made for a little more than \$2. The case of the iron-shell seems complete with these advantages, if they can be made under foundry conditions that will insure that they will be uniform and satisfactory in quality. To achieve these results Mr. Costa advocates the permanent mold, in which he has had wide experience. The theory of the cast-iron shell is that, when used against earth-works, the greater part of the explosion is not expended in bursting the walls of the shell, and the effect is as if the amount of explosive were detonated in the earth-work. When used in the open, the great fragmentation of cast-iron will allow the shell to burst into a far greater number of pieces than a steel shell, and to cover the zone of dispersion closely. There is nothing new, however, in the use of cast-iron projectiles. Before the age of steel they were the sole means of battering down defenses and of attacking at long range. Some reasons for their being abandoned are that the metal has never had a good reputation for uniformity and freedom from sponginess and gas-holes. Its tensile strength is low, and it lacks toughness. Casting in permanent, or metal molds, is claimed to rectify these and other defects.

THE HABER process has been investigated in the United States at the Arlington plant under control of the Department of Agriculture, and is economically producing synthetic ammonia. The plant is open to public inspection, and it is expected that large private industrial works will follow from this government initiative. The process is extensively applied in Germany.

*Abstract (Chem. Abst.): T. French, Trans. Am. Elect. Chem. Soc.

Lead Industry in 1917

The lead content of ore mined in the United States in 1917 was about 640,000 tons, this being an excess of 17,000 tons over the output in the previous year. Joplin gained 8000 tons, California over 5000 tons, Idaho 4000 tons, and Washington and Montana 2000 tons each. Tennessee suddenly rose from an insignificant output to nearly 3000 tons. Arizona and Utah lost about 4000 tons each and Colorado about 2000 tons as compared with 1916. The disseminated lead district of south-east Missouri remains the largest producer of lead, the output for 1917 being practically the same as in 1916. The Bunker Hill smelter at Kellogg, Idaho, was completed and put in operation during the year. The Empire Smelting & Refining Co. re-built the old smelter at Deming, New Mexico, and treated ores from April until October, when the plant was destroyed by fire. The Ontario Smelting & Refining Co. is building a soft-lead smelter in the north-eastern part of Oklahoma, a few miles south-west of Baxter Springs, Kansas. It will be equipped with four Newman automatic hearths, a lead blast-furnace, and a bag-house. The following estimates have been compiled by C. E. Siebenthal from reports made to the U. S. Geological Survey from all the lead refineries and soft-lead smelters that were in operation during the year.

DOMESTIC AND FOREIGN LEAD, ORES, AND BULLION. The production of refined lead, desilverized and soft, from domestic and foreign ores in 1917 is estimated at 599,000 tons, worth, at the average New York price, about \$110,000,000. The corresponding figures for 1916 were 571,134 tons and \$78,816,000. The figures for 1917 do not include an estimated output of 20,000 tons of antimonial lead, worth about \$4,600,000. The production of desilvered lead of domestic origin, exclusive of desilverized soft lead, is estimated at 297,000 tons, against 316,469 tons in 1916; and that of desilverized lead of foreign origin at 59,000 tons, compared with 18,906 tons in 1916. The production of soft lead from Mississippi Valley ores is estimated at 243,000 tons, compared with 235,759 tons in 1916. The final figures for the production of soft lead will show an increase of a few thousand tons over those here given. In consequence of the great demand and high price about 5000 tons of secondary lead, and over 4000 tons of secondary antimonial lead, were recovered at the regular smelters. Refiners of argentiferous lead treated some ores from the Mississippi valley, which is not reported separately.

IMPORTS AND EXPORTS. The imports of lead are estimated at 20,000 short tons of lead in ore, valued at \$2,200,000; 37,000 tons of lead in base bullion, valued at \$5,100,000; and 4400 tons of refined and old lead, valued at \$650,000, a total of 61,400 tons, valued at approximately \$8,000,000. The lead imported into the United States during the first 10 months of 1917, comprising lead in ore, bullion, and pigs, and old lead, originated as shown in the following table:

IMPORTS, JANUARY TO OCTOBER 1917. SHORT TONS

	From Mexico	From Canada	Other countries	Total
January	2,665	1,762	33	4,460
February	964	292	918	2,174
March	4,534	1,528	94	6,156
April	4,162	515	647	5,324
May	5,680	365	198	6,243
June	4,502	107	1,344	5,953
July	3,653	164	4,381	8,198
August	7,509	1	271	7,781
September	6,285	80	118	6,483
October	2,510	33	386	2,929

The exports of lead of foreign origin, smelted or refined in the United States, showed considerable increase. They are estimated at 17,000 tons, worth \$3,300,000, against 9880 tons in 1916. These figures do not include the lead in foreign lead manufacturers exported with benefit of drawback, which amounted to 3227 tons in the first half of 1917. For the last four years notable quantities of domestic lead have been exported to Europe, and the total for 1917 is estimated at 48,000 short tons, valued at \$8,300,000, compared with 100,565 tons, valued at \$13,508,203, in 1916.

PIG-LEAD EXPORTS, JANUARY TO OCTOBER 1917. SHORT TONS

	From domestic ores	From foreign ores
January	8,095	641
February	3,030	133
March	3,744	959
April	3,454	2,382
May	4,197	1,209
June	6,621	742
July	3,135	90
August	1,905	89
September	4,346	104
October	2,665	10,520

LEAD AVAILABLE FOR CONSUMPTION. The quantity of lead available during 1917 may be estimated by adding to the stock of foreign lead in bonded warehouses at the beginning of the year (12,369 short tons) the imports (about 61,400 tons), and the domestic production (540,000 tons), making an apparent supply of 614,000 tons. From this should be subtracted the exports of domestic lead (48,000 tons), the exports of foreign lead (about 17,000 tons), the foreign lead contained in articles exported with benefit of drawback (about 5000 tons) and the stock of foreign lead in bonded warehouses at the end of the year, which is assumed to be the same at the end of October, namely, 16,777 tons, leaving 527,000 tons available for consumption, compared with 477,384 tons in 1916.

MARKET PRICES FOR LEAD. At the beginning of 1917 the price of lead in New York was a little over 7.5c. per pound, but it soon began to rise, reaching 10.5c. late in February and early in March. There was a decline to 9.25c. early in April, but this was followed by a rise that reached 12.25c. in the middle of June. A sharp decline then set in, and although there was a slight recovery late in July and early in August, the price went down to 5.5c. in November. From this point the price gradually rose, and at the end of the year was about 7c. per pound.

Scientific Nominalism and Flotation Physics

By DUDLEY H. NORRIS

The science that treats of external Nature, aside from human consciousness, which science is generally called metaphysics, is divided, like all Gaul, into three parts: 'realism,' which holds that there is such an external existence; 'conceptualism,' which holds that all we can know is our intellectual impressions; and 'nominalism,' which holds that we cannot know a thing until we name it and that then we know only the name and nothing else—*vox et proterea nihil*. As concrete examples, Thomas Carlyle was a realist, John Stuart Mill was a conceptualist, and Immanuel Kant a nominalist. Carlyle wrote 'Sartor Resartus' as a burlesque on the Kantian philosophy, and in the burlesque the University of Königsberg appeared as Weissnichtwo, Kant as Professor Teufelsdröckh, and his philosophy as the Philosophy of Clothes, the basic principle of which philosophy was that it is only externals, clothes, that count, and that the human being inside them is nothing. To exemplify this principle Professor Teufelsdröckh discoursed of a great state ceremony with the Sovereign and other royalty, surrounded by a splendid court magnificently attired with jewels and decorations, when, suddenly, every stitch of clothing, every article of adornment vanished and of the gorgeous assembly nothing remained but the naked individuals composing it and these scurrying to concealment like rats to their holes.

Science has for centuries been dominated by nominalism. Sánchez, a Spanish philosopher of the 16th century, said that "science must be free from the word-lumber of the schools and put its questions directly to things themselves." This is just as true today as it was then; but we do not have to go over to Spain nor back to the 16th century to find it out. Within the past couple of years there have appeared in the MINING AND SCIENTIFIC PRESS perhaps half a dozen articles written to prove that flotation is caused by electricity, and in the course of the respective demonstrations the writers have made use of such words and phrases as surface-tension, electro-statics, polarity, electric charges positive and negative, electro-phoresis, electrical endosmose, dielectric films, contact-angles, contact-layers, electric charges of the bubbles, frictional electrifying of the bubbles and the pulp, hysteresis, ions, electrons, electric conductors, electrified bubbles, a conducting fluid, interfacial tension, osmotic pressure, liquid skins, all of which scientific scholastic epithets seem to be summed up in the despairing end of one article: "It is no wonder that great difficulty has been experienced in the practical application of flotation to ores, when such delicate electrical forces have to be considered." Still, in all these words

and phrases there is nothing that touches the reality of either flotation or electricity.

The great trouble is that these names and their corresponding mental images are projected into the objective universe and considered as realities forming part of it; thus cohesion, adhesion, adsorption, capillary attraction, and the terms used in magnetism and electricity and the rest, are generally so considered, whereas they exist only in the mind. The same is true of the widely current fallacy that "Time is no part of Eternity." As neither Time nor Eternity can be conceived as objective existences they cannot be compared as such. The point I desire to make is illustrated by the homely adventures of the four blind men with the elephant. One caught hold of his trunk, the second of his fore leg, the third bumped against his side, and the last caught hold of his tail. On comparing notes the first said that the elephant was very like a snake, the second like a tree, the third like a wall, and the last like a rope; and they were all justified in their conceptions of the elephant and yet he was not any of these things nor all combined.

One of the worst offenders in this direction is Professor Milliken, of Chicago, who has recently published a book, 'The Electron,' reviewed in the Eastern papers. Here is an extract from the book: "It looks as if the dream of Thales of Miletus had actually come true, and that we have not only found a primordial element out of which all substances are made, but that that primordial element is hydrogen itself." The basis of the 'electron' fallacy is the projection of the hypothetical mathematical point into Nature. It is a fiction of mathematics that a point has neither length, breadth, nor thickness, but only position; that a line has length, but neither breadth nor thickness, and may be imagined as made up of an infinite number of points placed side by side; that a plane surface is in the same way made up of lines and a volume of planes. As long as we realize that all this is a mere fiction, like the legal fiction of John Doe, no harm or confusion can come of it; but if we try to project the mathematical point into nature or to identify John Doe in the flesh, we are on a sleeveless errand. Then, in electricity we have another mystery, and as long as the whole matter is nothing but speculation it might as well be magnificent. When we tickle amber it laughs electricity, so we will call the projected point an ambre, or, better yet, use the Greek word for amber and call it an 'electron.'

The theory of a primordial element was not a dream of Thales, at all. It was a self-evident pre-supposition of the Ionic school of philosophy that a single cosmic mat-

ter lies at the base of the entire process of Nature and the only question was to determine what this elementary matter was. While solid matter appeared dead, moved only from without, the liquid and volatile made the impression of independent mobility. There was a school that held to 'hylozoism,' or the doctrine that this cosmic matter contained the essential principle of life, and included within itself, as an essential attribute, all the forces necessary to produce all natural phenomena; that it was essentially omnipotent. All this nucleus of the Ionian philosophy is tucked away in the first verse of the Gospel of St. John, but so badly translated that it can only be compared with Josh Billings' translation of '*tempus fugit*' as fly-time.

Thales ascribed souls to magnets and declared the whole world full of souls. He declared, 600 years B. C., that this cosmic matter was water. Anaximenes believed air to have a quality, namely, infinity, that water lacked. Heraclitus, 500 B. C., declared the world to be an ever-living fire. Empedocles, fifty years later, compromised. He admitted as elements these four subjects of popular thought and that they were each without beginning, imperishable, homogeneous, unchangeable, eternal, and indestructible; but he sought a cause for motion outside the elements and called that cause 'love' and 'hate.' If he had said 'attraction' and 'repulsion' Empedocles would have been fully abreast of 20th century science. As it was, he taught that animals had arisen here and there, without any rule, and that in course of time only those fitted for life in their surrounding circumstances maintained themselves and that man had no other origin than growth out of the animal world. Also, a mixture of elements where 'love' ruled and 'hate' was excluded, he called 'sphaïros,' which is Greek for 'sphere.' Thus Empedocles, only 150 years later than Thales, had invented 'survival of the fittest' and the 'descent of man,' anticipating Darwin some 2300 years; and he could have told our modern physicists that when water fell through space it needed no film nor any surface-tension to form a sphere. It did it 'on its own.' Anaxagoras, contemporary with Empedocles, hit upon a force-element that he called 'aether,' the lightest and most mobile of all elements.

These Ionians, inhabiting the Ionian islands, west of the Grecian mainland, were from their surroundings seafarers. They understood astronomy, navigation, and the tides; it was necessary for them to interpret natural phenomena, and from this necessity arose their development of the inductive logic and their wonderful understanding of the bases of natural philosophy. The greatest of the Ionian philosophers was Democritus, whose system, 460 to 360 B.C., was for the mechanical explanation of Nature. This means that unknown phenomena must be explained and interpreted in terms of our previous knowledge and not in terms of final causes, much less in terms of a theory invented on the spot and including in the purported solution of a problem the very terms of the problem itself.

In a recent lecture at the University of California

Aristotle was said to be a colossal failure as a scientist because he had said that a large heavy body would fall more rapidly than a small one, which Galileo proved to be erroneous. Aristotle was an Athenian, a disciple of Socrates, and Athens was at that time thoroughly degenerate. Mob rule prevailed, and sophism, the current philosophy, had for its supreme law of action the individual's natural disposition, his impulses. Aristides, a most estimable citizen, was banished by popular vote for no other reason than that people were tired of hearing him called 'the Just'. Oratory achieved an importance not since attained except during the French revolution and at the present time in Russia.

In Athens there were no intellectual amusements until there arose a game called 'dialectics', in which one man stopped another, as the Ancient Mariner stopped the Wedding Guest, and put to him a question that he must answer 'Yes' or 'No'. Then followed other questions and answers, until one or the other confessed defeat. Schools were started where this game was taught and books were written giving rules for the game. Aristotle was one of the many teachers of the game, and his book was considered about as Hoyle's 'Games' is with us. Time has shown that Aristotle's book, written under these unfavorable conditions, developing deductive logic, is one of the most splendid achievements of the human mind. Socrates put aside all natural science except as to final causes. His work was the moral regeneration of Athens, and if the millions of people who lived during the many centuries between Aristotle and Galileo had not wit enough to detect the error as to falling bodies, the fault lay with them. The submersion of the Ionian induction by the flood of Athenian deduction was a deplorable disaster to science, and it retarded the progress of scientific thought by over 1500 years.

All of this is preliminary to the consideration of the new book on flotation, in which Mr. Ralston gives a list of the various inventions in connection with bubble flotation, many of which he says were designed to avoid infringement. As far as can be judged from reading the descriptions, they did not succeed. Those of the first group include the mechanical frothers and the sub-aeration machines. Of the second group are the pneumatics, including the Callow and others that would probably have infringed the Callow if this had not already infringed the Minerals Separation. Of all these processes and patents only one, the Minerals Separation, collects tonnage-royalty. The others sell their machines at high prices leaving the purchaser full owner, with no further obligation, except to pay to the Minerals Separation such damages as may be assessed against him for infringement of patent No. 835,120.

Mr. Ralston also mentions a third group, if a single patent may be called a group. He says: "Dudley H. Norris invented the 'pressure' machine shown in Fig. 31." This patent is really only supplementary and shows a separation box, much like the Callow, adapted to the Norris process. There is also the Elmore vacuum with a minus pressure and these two are alike in that they

get their bubbles by reason of a reduced pressure. II. Hardy Smith also mentions "Mr. Norris's unique process, in which minute bubbles are 'born' in a pulp which is super-saturated with a gas." The only gas mentioned in my specification is air, but it may be called 'unique' for the added reason that it is the only process that has been attacked by the Minerals Separation and come off victorious.

When I filed my original application in Washington the examiner in the Patent Office criticized my use of the word 'naseent', just as Mr. Smith does now. I answered that as there was no chemical action, there could be no chemical nascent state; but that there was also in nature a physical nascent state, and that when bubbles formed out of solution, as in the Elmore vacuum and the Norris processes, they had a vigor of action at the instant of nascent state that was immediately lost; that if at that instant a metallic particle came in touch with the nascent bubble they stuck together, otherwise there was no flotation by that bubble. With that explanation the examiner allowed the specification to stand.

The explanation seemed at the time entirely commonplace. This was in 1906, and in those days the Minerals Separation had not developed its process, and Callow was far in the future. By 'flotation' one could only mean the Elmore vacuum process. But now that other processes have come into vogue, and no other explanation seems to be forthcoming, it may be worth while to see if there is anything in the notion of a physical nascent state. Mr. Coghill said in another connection that my theory that "each molecule of water is drawn toward the centre of gravity of its mass cannot be taken as a substitute for the accepted theory of surface-tension, for it is not in accord with physicists here or abroad." I recognize the overwhelming force of this argument, just as Galileo did about the falling bodies, but the world moves notwithstanding. At any rate my idea of water forming a sphere when acted on by its own molecular force alone agrees with Empedocles, and I certainly prefer that to Jones's definition: "potential energy, present at the surface of liquids, produces a tension which is known as surface-tension." Webster defines potential as "existing in possibility, not in act." So that the definition becomes "an energy that might possibly exist at the surface of liquids, but in fact does not, produces a tension which is known as surface-tension;" which, after all, is just about my idea of surface-tension.

In the Minerals Separation process the air seems to be drawn in by friction rather than beaten in by blows, and as they are carried around the bubbles become elongated and finally torn apart. When these ruptures or solutions of continuity take place and there happens that a particle of valuable mineral is at the point of rupture, at the instant of rupture the essential act preceding flotation takes place, in the same way as in the two pressure processes, and it is only with the junction of the mineral particle and the broken bubble that flotation ensues.

The same with the Callow process: With a gentle pressure of air the bubbles are few in number and of large

size. With more pressure the bubbles are smaller and vastly more numerous. The function of the canvas cannot be to make fine bubbles, for it does not do that. The elongated bubbles break off at the canvas and the union with the metallic particles takes place then and there, or not at all. That is, if there is anything in the idea of a physical nascent state.

From Mr. Free's admirable article on 'Colloids' it might easily be that these show evidence of a physical nascent state. Of course, the difference between what we call 'physical' and what we call 'chemical' does not exist in nature. It is one that we make for the convenience of work and study; the line between them is broadly rather than sharply marked. I have never been able to find a thoroughfare through this border-land and the idea of a physical nascent state may point a way.

With regard to Stokes' formula for falling bodies, quoted by Mr. Free:

$$v = \frac{2}{9k} r^2 (d - d') g$$

in which v is the velocity, r the radius of the particle, d and d' the densities of the particle and the medium respectively, and k a constant, depending on the viscosity of the solution, Mr. Free says that the smaller particles fall more slowly than the theory calls for. The square of the radius would be correct if the rate of fall were proportional to the cross-section of the particle; whereas, if the rate were proportional to the mass, as may easily be the case, it ought to be the cube of the radius.

The specification of the Elmore vacuum patent said that bubble-flotation processes are improved in the respect that a smaller proportion of oil or acid may be used by conducting the processes under a reduced pressure; but his claim called for the use of only such pressures as were below that of the atmosphere, although his discovery included all possible higher pressures. Any flotation that might be produced by these pressures above atmospheric normal were at the service of any one who might claim them. The only difficulty would be to devise a way to utilize these higher pressures as bubble-producers.

At this point happened the incident of the Pullman car wash-basin, mentioned by Mr. Rakston, and the rest was easy. All fresh water is rainwater that has fallen through the terrestrial atmosphere, whose density is measured by a maximum pressure of 15 pounds per square inch. The Norris process takes in all these higher pressures, beginning where Elmore left off. The patent provides for a closed receptacle filled with compressed air into which a fine spray of water is introduced at the top of the receptacle and falls through the compressed air to the bottom of the receptacle, where it forms a solid body of water charged with air. The degree of aeration depends upon the pressure of the air in the receptacle, the fineness of the spray, the distance through which the spray falls, the time consumed in falling, and the temperature.

In his article on 'The Theory of Flotation' Mr. Hardy Smith says, under 'segregation No. 1', that "No amount

of agitation or blowing will produce bubbles of the right kind and number in absolutely pure water. A contaminating agent is necessary." Also, that "the action of certain substances in producing innumerable minute bubbles when air is introduced forcibly into a pulp, seems to be of fundamental importance, since without these bubbles the most common forms of froth-flotation cannot be considered." Referring to the work of Professor Pollock, Mr. Smith says of this all-important subject that "with pure water the bubbles were mostly large, and even the small ones which were instantaneously produced had a tendency to collect together to form large ones."

Any one familiar with the milky appearance of the water in the Pullman car and of the water of the cities on San Francisco bay which get their water-supply from the mountains, knows that the bubbles which cause the milky appearance answer to Mr. Smith's description of "innumerable" and "minute" and that they are produced in pure and uncontaminated water, that they do not coalesce and form larger bubbles but continue to maintain the size best adapted to successful flotation. The same phrase "innumerable minute" exactly describes the bubbles produced by what Mr. Ralston calls a 'pressure' process, meaning the Norris process, which term also designates the Elmore vacuum. In my original specification in 1906 it was called "the continuous action of infinitesimally small nascent bubbles of air," and my idea has always been that the use of oil is merely to make a tougher bubble, give the molecular action what name you please. Mr. Smith also gives it as an established fact that for a bubble and a solid to become attached "so that its film forms part of a continuous film covering both solid and gas, there must be some force that causes rupture of the bubble-film at the point of contact," which seems neither more nor less than actual proof of a principle that appealed to me ten years ago as the theory of a physical nascent state.

I applied for a patent in London and I was notified, later on, that I was opposed by Minerals Separation, of whom I thus heard for the first time. Naturally, I was surprised at this notice as being entirely different from the American practice, with which I was familiar. Rule 15 of the American Patent Office provides that "pending applications are preserved in secrecy." In case of a question as to priority of invention between two parties a proceeding called an 'interference' is initiated by the Patent Office itself and the only question involved in that of priority between the two inventions; but this was no interference, it was called an 'opposition'. I had no desire to engage in a patent litigation in a foreign country and I notified my patent attorneys not to appear. Later on, I received a copy of the decision of the London Patent Office, entitled thus:

In the matter of an application by
Dudley Hiram Norris for Letters Patent
No. 14806 dated 27th June 1907. And.

In the matter of an opposition by
Minerals Separation, Limited, to the
Grant of the Patent thereon.

The first thing to be noticed from the above titles is that "Pending applications are *not* preserved in secrecy" in the British Patent Office: that parties not privy to the application have the right of access to the records and to oppose the grant of the patent or to profit by the disclosure of what in the Washington practice is "preserved in secrecy."

The Elmore vacuum application was filed in London on August 16, 1904, and that of Minerals Separation for the British patent corresponding to 835,120 on April 12, 1905, eight months later. According to the record of events as told by Mr. Rickard in 'Flotation' on page 22, Minerals Separation had been developing the process of the Cattermole patent "when suddenly they happened upon the particular combination essential to the froth-agitation process. Messrs. Ballot, Sulman, and Picard agree in stating that protracted experiments were being conducted in their London laboratory under the immediate charge of Arthur H. Higgins, who had been instructed to try all sorts of variations in temperature, acidulation, oiling, and mixing. Nothing noteworthy happened until the proportion of oil was reduced, whereupon the 'granules' began to rise instead of sink and 'the quantity of floating material increased rapidly when the oil was reduced below a certain point, this point being 0.62% of the oleic acid on the ore.' So testifies Mr. Ballot. Thus happened 'the startling discovery of the agitation-froth process' according to W. H. Ballantyne, Mr. Ballot's patent lawyer. The date was March 3, 1905. Then followed the British patent No. 7803 of April 12, 1905, and the American duplicate, No. 835,120."

That is their story as they themselves tell it. No mention is made in all this of the Elmore vacuum patent, although they were in touch with the Elmores for years. were treated with the greatest frankness, as Stanley Elmore says, and it is incredible that they did not have full information of Frank Elmore's patent activities. There is no reason to doubt that Mr. Ballantyne had the same ready access to the records of the London Patent Office during the pendency of the application for the Elmore vacuum patent that he had in that of the Norris patent.

Elmore adds to his flowing mixture "a substance that has a selective affinity for some of the constituents"; Sulman adds "an oily liquid having a preferential affinity for metalliferous matter." Elmore provides for "a smaller proportion of oil" or acid to be used by conducting the process under a reduced pressure; Sulman specifies "a small quantity of oil;" Elmore had brought down the amount of oil to three pounds per ton of ore; Sulman patented the use of "a fraction of 1% on the ore" or less than 20 pounds. Elmore produces his bubbles by a reduction of pressure below that of the atmosphere; Sulman was not satisfied with the bubbles from the Gabbett mixer but "in an alternative method" produces bubbles by a reduction of pressure, but raises the pressure first to "one or two atmospheres" in one place and to "50 to 100

pounds to the square inch" in another and then lowers it to atmospheric normal.

The Sulman patent is a curiosity. It shows two figures, the first one being for the process evolved from the Gabbett mixer, and Fig. 2 for the pressure process derived from the Elmore. The original application was divided and the second part was granted as No. 835,479. The curious part of 835,120 is that the part of the first specification, which relates to the pressure process, was allowed to remain in the original specification, but without any corresponding claim. The examiner at the Patent Office should have insisted on canceling the 'alternative' method in 835,120 when the application was divided. The machine shown in the drawing of 835,479 is a thing of shreds and patches. It never could run and it never was expected to run. Like many such, it was merely intended to accompany the specifications. Neither Mr. Higgins nor any other man with any experience in a concentrating mill could have designed it.

And yet, Mr. Williams, for the plaintiff, in the Butte & Superior case, had the nerve to bring this monstrosity to the attention of the Court. He spoke of a spitzkasten-classifier, an agitation vessel, a "suggestion" of a shaking table, also another "suggestion" of another method of treatment which he endowed with the agitation-by-aeration feature of the pneumatic cells, and finally "the gas was generated throughout the mass at once, sweeping to the surface thereof all the metalliferous matter in the form of a froth." No wonder the Court asked if that was in the patent in suit and Mr. Williams answered that it was, but at the time of the Hyde case they had not then found out how to use it. He might have added "nor yet." And still the Court was not satisfied, and said: "You don't mean it is claimed in the patent in suit?" and finally Mr. Williams read to the Court claim 1 of 835,120, which has absolutely nothing to do with the 'alternative' process.

The claims of patent 835,479 are three in number:

Claim 1 says: "The process of separating powdered minerals from one another which consists in suspending the powdered minerals in a liquid, subjecting the mixture to a gas pressure and thereafter relieving the pressure whereby bubbles of gas are liberated in the pulp and carry certain minerals to the surface;" claim 2 is the same except that it adds "a small quantity of oil" to the mixture; and claim 3 repeats claim 2 and adds that the pulp is run out into a separating-box. Claim 1 uses no oil; claim 2 uses "a small quantity of oil" the same as in the claim 9 of 835,120 that the U. S. Supreme Court held invalid, and claim 3 uses a spitzkasten, or separation-box, which surely is no novelty.

Mr. Choate said that in matters of litigation it was not enough to know the law, one must sometimes know the judge; meaning that the personality and psychology of the judge is often as essential in a case as the law and the evidence. The legal profession, including the judiciary, are trained exclusively in deductive logic. The existing body of jurisprudence, including the common law, the statutes, and the decisions of the higher courts, forms the

major premise; the case at bar, the minor premise; the judge applies the rules of the science and the conclusion is the decision of the Court, or the basis of it. Where, as in a case involving scientific experiments or physical tests, the logic to be applied is inductive, which may be said to give the conclusion and one premise, to find the other, it seems like going backward and the Court balks. Judges are not wise above that which is written and a good strong patent specification is worth a wilderness of physical tests. Courts are suspicious of such tests; afraid of being deceived, intentionally or by reason of the unconscious bias or one-sidedness of the expert making the test. Any word or phrase that will enable him to apply the predicables of Aristotle and the canons of the syllogism and decide the case without considering the physical tests, will receive the judge's instant and welcome attention. In confirmation of the contention that this tendency of the judicial mind goes with the deductive habit of thought, there is the curious parallel between the uniform course of the courts in the flotation cases and the decision of Aristotle, the father of the deductive logic, in the case of the falling bodies.

In the Callow specification it was stated that in the previous art of flotation "the mixture is then subjected to a violent agitation by means of mechanical propellers", which was an erroneous statement, as the specification and claim of 835,120 said nothing about mechanical propellers. Then, later on, the Callow specification says, "a more or less violent agitation or ebullition takes place and a froth begins to generate and to finally rise and form on the surface of the pulp." A confession of infringement hardly could be expressed in terms more explicit.

It has been a great misfortune that the Elmore vacuum patent was not before the courts. It would have prevented the continued laudation of the Minerals Separation, culminating in the U. S. Supreme Court's "Into this field of investigation came the patentees of the patent in suit" and a lot more of the same kind. But, Elmore chose his own share of his discovery and took only that part below atmospheric pressure, and evidence as to the higher pressures would not have been material to the issues involving 835,120, which agitates to form a froth; but, with the pressure-processes in suit the Elmore vacuum patent, antedating 835,120, would be very material to the new issues; and while the Elmore vacuum does not claim the higher pressures, above atmospheric normal, it specifies these higher pressures and the Norris process claims them; and as against that claim 835,120 could not be effectively pleaded, but only 835,479, which is no process at all and, moreover, it was decided in the British Patent Office that the Norris basic patent did not infringe the Minerals Separation patent and this decision was affirmed on appeal and these proceedings were on the merits and before a competent tribunal and the Minerals Separation was represented. So that, this decision might easily be held to be, as between the same parties or their legal representatives, *res judicata*, and not to be re-opened collaterally.

Efficiency of Gravel Pumps

The following details of the gravel-pumping plant at the Heawood tin mine in the Federated Malay States are taken from a paper by J. J. Garrard published in Bull. No. 156 of the Institution of Mining and Metallurgy. The plant consists of two monitors and an 8-in. gravel-pump driven with a long belt by a Pelton wheel. The material is elevated into a two-compartment sluice-box. The Pelton wheel is above the sluice-box, and the discharge water is used for 'cleaning up,' the boxes being streamed down on separate days, and also to assist in the sluicing when the two compartments are running at the same time. The size of the Pelton wheel is 24 in., and the nozzle is controlled by a needle valve having a maximum size of 1½ in. The gauge-pressure is 220 lb. per sq. in., the nozzle being 6 ft. 6 in. above the gauge.

Effective head = 508 - 6 ft. 6 in. = 501.5 or say 500 ft.

Measurements of the water were taken at a rectangular weir, 20 in. wide, at the discharge of the wheel, the depth of the water flowing over weir being 5½ inches.

Quantity of water = $4.67 \times 20 = 93.40$ cu. ft. per min.

Theoretical hp. =

$$\frac{\text{weight of water (lb.)} \times \text{effective head (ft.)}}{33000} = \frac{93.40 \times 62.5 \times 500}{33000} = 88.44$$

The gravel-pump lifts the water and solids from two 2-in. monitors at 65 lb. pressure and also an estimated

S = cu. ft. per min. (solids).....	55.5 cu. ft.
W = cu. ft. per min. of water lifted (2—2 in. monitors at 6 lb. + 20 cu. ft. seepage = $120.9 \times 2 + 20$).....	261.8 cu. ft.
T = theoretical hp. (Pelton wheel 93.40 cu. ft. per min. at 500 ft. (effective head).....	88.44 hp.
P = brake-hp. (at 75% efficiency).....	66.33 hp.
Overall efficiency of plant =	

$$\begin{aligned} \frac{\text{work done}}{\text{worked applied}} &= \frac{H(62.3 W + 100 S)}{T \times 33000} \\ &= \frac{H(62.3 W + 45 G)}{T \times 33000} \\ &= \frac{45.7 (62.3 \times 261.8 + 45 \times 25)}{88.44 \times 33000} \\ &= \frac{796785.90}{2918520} = 0.2730 = 27.30\% \end{aligned}$$

Mechanical efficiency of gravel-pump, including long belt-drive (efficiency of Pelton wheel estimated at 75%) is:

$$M.E. = \frac{27.30}{75} = 36.40\%$$

A series of tests showed that a gravel-pump driven with a belt by a Pelton wheel will have an efficiency of 27%; when water-power is converted into electricity the gravel-pumping plant-efficiency will be 23%. At least 15% efficiency may be expected from a hydraulic elevator. The system installed will depend, among other things, upon the configuration of the ground and the quantity and situation of the water-supply.

ADVICES from London give last month's shipments of nitrate from Chile as 285,000 tons, 96,000 tons going to Europe and 148,000 to the United States. The exports to Japan, Siberia, and other countries were 41,000 tons. It is interesting to note that in October, 1913, the year before the War, 260,000 tons of nitrate was shipped to Europe in anticipation of the agricultural season, and only 46,000 tons to the United States. In the same month, in 1914, after the commencement of hostilities, the respective quantities were 49,000 and 13,000 tons, the article having been declared "contraband of war," and the principal continental markets being closed. The production

of nitrate of soda, notwithstanding the supposed scarcity of fuel, is above that of peace times, last month's total being no less than 258,400 tons, compared with 229,990 tons in October, and stocks in Chile reduced to the extent of 32,000 tons by the excess of exports, are now over 850,000 tons. This being 100,000 tons more than at this time last year, there is some difficulty in explaining the advance in the f.o.b. price from 9s. per quintal 12 months ago to about 16s. at the beginning of last month. The speculative spurt has, however, since died out, the sale of the German stocks having knocked the bottom out of the market, and prices on the West Coast are, at the time of writing, quite nominal. Business on the side has been brought to a standstill by Government control, and further official notifications in the shape of maximum prices or permits are awaited by the trade. Present prices for nitrate of soda at New York are \$4.50 to \$4.60 for 95% material.

ARRANGEMENT OF PUMP INSTALLATION

quantity of 20 cu. ft. per min. of seepage water. The duty of the monitors is shown below:

Nozzles	2—2 in.
Pressure	each 65 lb. per sq. in.
Effective head	150 ft.
Discharge	$2 \times 120.9 = 241.8$ cu. ft. per min.
Seepage	20 cu. ft. per min.
Total water raised	261.8 cu. ft. per min.
Yardage cut (monthly survey)	18,000.0 cu. yd.

The ground treated is a soft clay soil containing about 50% sand; 9.67 cu. ft. of water per min. is required to break down 1 cu. yd. of ground per hour.

The determination of the mechanical efficiency of the gravel-pump is as follows:

Size	8 in.
Speed	482 r.p.m.
H = height lifted in feet.....	45.7 ft.
Q = cu. yd. per month (solids).....	18,000.0 cu. yd.
G = cu. yd. per hour (solids).....	25.0 cu. yd.

Sea-Water for Flotation

BY AN OCCASIONAL CORRESPONDENT

There is being developed, in an experimental concentrator in the North-West, an interesting departure from standard practice in the flotation-concentration of copper ores.

These ores contain, as the valuable mineral, cupriferous pyrite, accompanied by barren pyrite and by pyrrhotite, in a schistose gangue. Efforts are being made to develop an efficient process by which the cupriferous pyrite may be floated, not only selectively from the gangue, but preferentially from the pyrite and pyrrhotite.

While much valuable work has been done with oils, particularly with straight Californian fuel-oils, it is the purpose of this article to describe results obtained without the use of oil or similar substances. These results appear to upset many pet theories heretofore advanced, particularly the contention that selective flotation results from the coating of sulphide minerals by oil, and that froth results from a lowering of the surface-tension of water.

Briefly, the process consists in circulating and aerating an ore-pulp containing an electrolyte in solution, no oils or oily substances being present. The original discovery, on which this process is based, was made on March 5, 1917, when a laboratory test was made using commercial waterglass in the proportion of about 5 lb. per ton of ore. The test was made upon an ore containing about 3% cupriferous pyrite and 11% pyrrhotite, assaying 0.74% copper, 15.6% iron, 5.5% sulphur, and 54.4% insoluble. From 500 grammes of ore, 12 gm. of concentrate was obtained, assaying 16.70% copper, 38.3% iron, 41.4% sulphur, and 2.3% insoluble. No single particle of pyrrhotite in the concentrate could be detected with a microscope.

This discovery was not followed up at the time owing to press of other work, but a little later, while some tests were being made on the use of oil with salt water, it was found that the salt solution gave a similar preferential flotation of cupriferous pyrite. Other electrolytes were then experimented with, including sodium sulphate, carbonate, bi-carbonate, sulphite, and thio-sulphate; magnesium chloride and sulphate; calcium chloride and carbonate; ammonium chloride and carbonate; sulphuric acid; and other substances. In general it appeared that chlorides gave the best results. For example, the following are the results of some tests made in a Janney laboratory machine upon an ore containing about 7% cupriferous pyrite and 9% pyrrhotite, assaying 1.75% copper, 18.9% iron, 5.9% sulphur, and 47.4% insoluble.

A. ORDINARY TAP-WATER PLUS 15 GM. SODIUM CHLORIDE

Product	Weight Gm.	Assay, %			
		Copper	Iron	Sulphur	Insoluble
Concentrate .	56	15.35	28.3	23.9	16.6
Middling	24	0.72	32.5	15.1	30.4
Tailing	417	0.07	16.4	3.2	53.4

B. ORDINARY TAP-WATER WITH 30 GM. MAGNESIUM CHLORIDE

Product	Weight Gm.	Assay, %			
		Copper	Iron	Sulphur	Insoluble
Concentrate .	33	23.68	31.3	29.4	5.4
Middling	29	1.32	27.0	10.6	32.4
Tailing	440	0.26	16.7	3.8	51.4

C. ORDINARY SEA-WATER TO WHICH NO REAGENT WAS ADDED

Product	Weight Gm.	Assay, %			
		Copper	Iron	Sulphur	Insoluble
Concentrate .	39	21.61	34.3	31.2	6.4
Middling	39	0.71	34.9	16.2	26.0
Tailing	421	0.09	15.2	2.6	56.6

Two short trial runs have been made in the experimental concentrator, using salt in place of oil, in a unit consisting of one Janney emulsifier and six regular Janney cells. The cells were emptied and washed out with a hose, then allowed to fill with fresh pulp. When full, and circulating properly, salt was added by dumping a half-sack at a time into the emulsifier. A rather meagre but exceptionally clean mineral-froth immediately appeared. When the entire machine was operating smoothly, grab-samples were taken of the froth from each of the six cells, and of the tailing. Assays were as follows:

Product		Assay, %		
		Copper	Sulphur	Insoluble
Froth-cell No. 1.....	12.20	29.0	19.2	
Froth-cell No. 2.....	16.48	32.2	6.2	
Froth-cell No. 3.....	16.60	29.6	7.6	
Froth-cell No. 4.....	8.92	
Froth-cell No. 5.....	10.28	
Froth-cell No. 6.....	5.04	
Tailing	0.21	6.3	...	

The mill-heading for the day on which this test was made assayed 1.24% copper, 19.0% iron, 9.9% sulphur, and 44.4% insoluble. Attention is particularly directed to the large amount of sulphur remaining in the tailing, from which the copper has been quite well removed.

Another similar run was made at a later date upon a more difficult ore, assaying 2.21% copper, 26.0% iron, 21.1% sulphur, 34.0% insoluble. The machine was not circulating as efficiently as when the former test was made and for this, as well as other possible reasons, a clean tailing was not made. For the entire shift, when salt was being used, the concentrate assayed 13.56% copper, 26.9% sulphur, and 16.2% insoluble, the return middling 6.0% copper, and the tailing 0.77% copper

and 15.7% sulphur. Grab-samples taken at a time when the machine was operating at its best gave the following results:

Product	Assay, %		
	Copper	Sulphur	Insoluble
Froth-cell No. 1.....	20.08	29.8	7.0
Froth-cell No. 2.....	14.68	25.9	11.0
Froth-cell No. 3.....	15.64	27.6	9.6
Froth-cell No. 4.....	13.60	25.3	13.8
Froth-cell No. 5.....	16.08	26.1	10.8
Froth-cell No. 6.....	13.32	26.9	10.8
All froth to thickener.....	17.76	28.6	13.0

The concentration of the salt in the pulp-water was slightly higher than in normal sea-water.

Not only do these inorganic salts give a more markedly preferential flotation of the cupriferos pyrite, but, there being no oil in the froth, it breaks down readily and does not accumulate on thickeners as oil-froths have a troublesome habit of doing. The concentrate is usually cleaner of gangue than when oils are used.

Some few experiments have been made on other than chalcopyrite ores, with rather poor results. Tests were made upon an ore containing both chalcopyrite and bornite. A practically complete flotation of the former was made, but the latter was hardly affected. A test was made on a 'porphyry' copper ore containing chalcocite. A voluminous froth was formed, but it was non-selective. It appears that the nature of the gangue has an important bearing on the flotative effect of these reagents. For example, poor results were obtained in attempting to float pure clean chalcopyrite from a pure clean quartz gangue. Much work remains to be done to prove the limits of applicability of this process, but in the case of ore deposits adjacent to the ocean, or to inland saline waters, there are attractive possibilities in the way of increased metallurgical efficiency, saving of oil, and freedom from annoyance by the owners of oil-flotation patents.

Arizona Mine Output 1917

The output of gold, silver, copper, lead, and zinc from Arizona mines in 1917, according to Victor C. Heikes, of the U. S. Geological Survey, had a total value of over \$214,000,000, an increase of more than \$23,000,000 over the value of the output in 1916. This increase was due in part to the greater prices of metals, all of which, except zinc, were decidedly higher in 1917. In quantity there was a marked increase in gold, a slight increase in recoverable zinc, but decreases in silver, copper, and lead. During the early part of the year Arizona was producing copper at a rate decidedly greater than in 1916, but labor strikes at the main producing and smelting localities considerably reduced the rate before the end of the year. Many mills were built, among them a custom-mill at Chloride and a sampler at Wickenburg. Construction was begun on the new smelter for the United Verde Extension Co. at Jerome. The capacity of the Arizona Binghamton mill was increased to 250 tons per day.

The production of gold from Arizona mines increased from \$3,985,559 in 1916 to \$4,831,000 in 1917. As the production of copper ore and of lead ore were much less than in 1916 the increase in the output of gold can be credited to the San Francisco district, of Mohave county, and largely to the United Eastern property, which, during the year, became the leading producer of gold in the State. The Gold Road mill was idle and the Vulture property was operated only a little. Production at the Tom Reed was upheld, and considerable gold was produced from the Copper Chief mine, in the Verde district.

The mine output of silver decreased from 7,212,039 oz. in 1916 to about 6,354,000 oz. in 1917, a decrease of about 858,000 oz. In spite of this decrease, the improved price of silver, which averaged 81.4 cents per ounce, brought the value of the output to about \$5,000,000, an increase from \$4,745,522 in 1916. The decrease in quantity was due to decreased shipments of lead ore and copper ore.

The mine output of copper was about 688,000,000 lb., a decrease of 34,000,000 lb., or nearly 5%. Arizona is still the leading copper-mining State and produced more than twice as much copper as Montana. The value of the output increased from \$177,570,960 in 1916 to over \$200,000,000 in 1917. Six of the large copper-smelting plants reported decreased outputs on account of labor troubles. Five others, however, greatly increased their copper production: the Hayden, Saseo, United Verde, Consolidated Arizona, and Calumet & Arizona. At the New Cornelia property the new leaching plant was started in June and produced more than 2,000,000 lb. per month until the end of the year. Some copper matte was shipped from the Great Western smelter, in the Big Bug district. The International Smelting Co. increased its capacity by adding a reverberatory furnace.

The mine production of lead in Arizona decreased from 27,062,087 lb. in 1916 to about 18,000,000 lb. in 1917, but as the price was better the value was only slightly less than that of 1916, which was \$1,867,284. Most of the lead ore came from the Warren district, of Cochise county, and the Wallapai district, of Mohave county. Considerable lead ore was shipped from the Bunker Hill mines, in the Tombstone district.

The output of recoverable zinc was about 20,700,000 lb. in 1917, an increase of about a million pounds. The two largest producers were the Union Basin property and the Tennessee mine, both in the Wallapai district, of Mohave county. The Arizona Hillside property, at Hillside, shipped considerable quantities of zinc ore for the first time, and the properties operated by Randolph & Gemmill at Crown King also made some shipments. Zinc was shipped from the Duquesne property, in Santa Cruz county. Smaller shipments were made from Wallapai district and from Globe, Patagonia, Pearce, Tucson, and Casa Grande. The mill of the Union Basin property was burned in October.

The dividends for eleven months from Arizona properties amounted to more than \$41,000,000.

REVIEW OF MINING

MAMMOTH, UTAH

ORE SHIPMENTS.—EMPIRE MINES.—IRON BLOSSOM.—KNIGHT MINES.—UTAH MINING CO.

Owing to inclement weather and an accident to the main-line switch the shipment from the Tintic district is far below normal for the week ended January 18; the total being 141 cars as compared with 175 of the previous week. The shippers were: Bingham Con. 31 cars, Chief Con. 15, Iron Blossom, 15, Gemini 13, Centennial Eureka 12, Mammoth 12, Grand Central 11, Eagle & Blue Bell 11, Tintic Standard 6, Gold Chain 4,

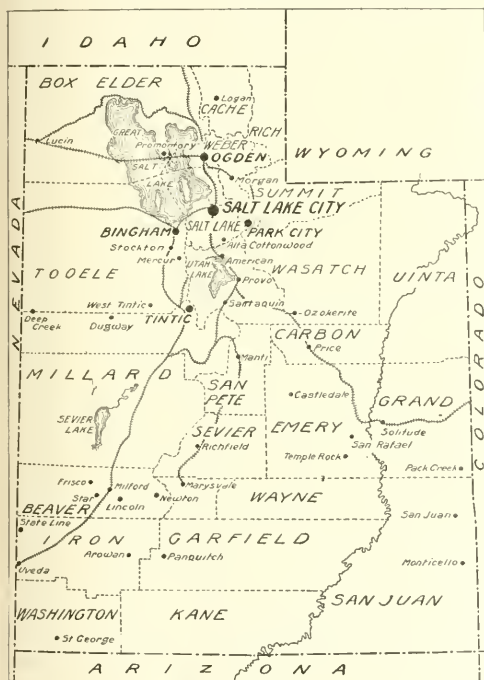

east. There is little leasing in the Lower Mammoth part of the Empire ground but over in the Carisa section lessees are operating four or five blocks of ground at a profit.—At a recent meeting of the Chief Consolidated directors the regular dividend of 5c. per share and an extra dividend in the same amount were declared, payable in February. Cecil Fitch, superintendent for the Chief Con., left early in the week for Michigan to attend a meeting of the directors of the company.—By the end of January it is expected that the No. 1 shaft of the Iron Blossom company will have reached a depth of 2200 ft. where sinking will be stopped and preparations made for the thorough prospecting of the ground. In the north end of this mine, at the No. 3 shaft, considerable copper ore is being mined from the 900 to the 1200-ft. levels. The drift from the 1700-ft. level, driven over into the Tintic Central, is cutting a likely looking section of the ground. The drift has been in a loose cavy formation, which is iron-stained and has other indications of the more valuable minerals. This mine shipped 15 cars of first-class ore this week.—On January 11 and 12 there was a shortage of electric power in the Tintic district, due to a temporary difficulty at the Provo plant of the Utah Power Co., and as a result the crushing plant of the Tintic Milling Co. was closed down for the two days, but it did not affect the other part of the mill.

The officials of the Knight companies state that satisfactory progress is being made at the drain-tunnel which will be driven from the south-west of Elberta on the Goshen slope to the heart of the Tintic mining district, draining the properties controlled by Jesse Knight as well as other South Tintic mines. Work was taken up late last year but three or four months were required to erect the necessary buildings and machinery. Work in the tunnel commenced only a short time ago but owing to the soft ground rapid work has been possible.—The Utah Mining Co. at Fish Springs has passed into the hands of Daniel Livingston and J. A. Rich, who will erect a concentrating plant to treat the many thousands of tons of low-grade ore. The property is a considerable distance from the railroad and at the time the mine was paying its big dividends no effort was made to handle anything less than \$100 ore, consequently the dump contains considerable good ore.—Four carloads of ore were shipped last year from the Eighty-Eight property and the Desert Mountain shipped the same amount. The latter mine is splendidly equipped for deep work. The Desert Mountain shaft has reached a depth of 350 ft., where a large body of low-grade copper ore was found.—As a result of the heavy snow-storm of the early part of the week, the hauling of ore from the Iron King property was suspended, but will be resumed in the near future. The ore which is now being shipped from this mine is an iron ore, which the smelters are using for fluxing purposes.

MAYER, ARIZONA

CONSOLIDATED ARIZONA.—DE SOTA.—BARBARA.

The Consolidated Arizona Co. will spend \$50,000 on the further development of the Blue Bell mine this year. The new work will consist of diamond-drilling horizontally on the lower levels, running a drift on the 800-ft. level at the south end of the mine to tap the ore that has recently been opened at 75 ft.,

MAP OF UTAH

Victoria 2, Tintic Milling Co. (bullion) 1, Eureka Hill 1, Victor lease 1, Yankee Con. 1, Chief Con. (manganese lease) 1, Iron King 1, Minnie Moore 1, Colorado 1, Empire Mines 1, making a total of 141 cars. Two important pieces of development work are under way in the main section of the Empire Mines property, which is a consolidation of a half dozen large tracts of mineral ground in the central part of this district. This work is being done through the old Lower Mammoth shaft and conditions are encouraging both on the 1500 and the 1800-ft. levels. On the 1500-ft. a drift is being run into new territory west of the shaft and the 1800-ft. drift is headed out toward the

and doing further work on the new 1200-ft. level. Already the new work on the 1200-ft. level has cut the big orebody that furnished a third of the output of the mine last year on the 1000-ft. level. In the drift that is being run north from the shaft at 1200 ft. the south end of the lense of ore has been struck and followed about 75 ft. At the south end on the 1000-ft. level this orebody tapers down, but on the 1200-ft. level, it is widening as the drift goes north. So far the orebody is 15 to 16 ft. wide and runs 4 to 4½ copper and \$6 to \$8 in gold and silver, which is slightly richer on the level above. The output for the past year was 100,000 tons.—At the DeSota mine, owned by the same company, the shaft will be sunk to 300 ft. While this mine is only about three miles south-west of the Blue Bell, it is found that the ore is more silicious and about the same richness. The ore lenses, though not so long, are thicker and are more numerous. The mine produced 50,000 tons last year.—Between these two mines there are several properties that show an outcrop indicating that the ore may be found in the same courses as in the mines at each end. The Blue Bell Extension Copper Co. began to sink a shaft a short distance over the south of the Blue Bell line last week. The company was organized by J. E. Garber, who is president, and C. J. Murdock, who is vice-president; both have been in the employ of the Consolidated Arizona Co. at the Blue Bell mine for several years. The work at the shaft is in charge of C. J. Murdock.

Probably no strike of ore at Mayer has been heralded with so much enthusiasm as the one just made in the Binghamton mine. In a drift run north 1400 ft. from the main shaft on the 100-ft. level ore has been cut and followed about 20 ft.; assays run from 4 to 23% copper. It is in an entirely new ore-zone, the nearest orebody being 800 ft. away. On the 600-ft. level, a drift run south struck the extension of the large ore-lense on the 400-ft. level. Face samples run from 6 to 27% copper. Diamond-drilling on this level is blocking out an orebody recently determined to be 30 to 50 ft. wide. It is estimated that the mine has five years of ore in sight at the present capacity of the mill, which is about 200 tons daily.—The taking over of the Barbara mine by the newly-organized Monte de Cobre Copper Co. was completed this week. The officers are: President, W. A. Tucker, of Bisbee; vice-president, John Ross, of Bisbee; secretary, E. M. Walker, Mayer; and treasurer, J. R. Robertson, Mayer. For the past four months the development of a large group of claims at the south end of Copper mountain has been in progress, the capital having been furnished by the Bisbee people. A cross-cut adit has already passed through about 40 ft. of poor-grade vein-matter.

PLATTEVILLE, WISCONSIN

HIRD MINES.—NEW ZINC DEPOSITS.—BLEWETT MINING CO.

The Frontier Mining Co., operating the Calvert, Bull Moose, Burr, Middle, Grotkin, and Hird No. 3 and 4 mines, all under the management of J. H. Billingsley, offers one of the most interesting mining combinations known to the Wisconsin zinc field. A new basin has been opened at the Calvert mine which yields 150 tons of 40% zinc concentrate weekly. The Bull Moose is opening a new range east of that now followed and anticipates an output of 250 tons of 42% zinc ore weekly; the Burr is opening a basin, containing several months run, on the Schultz allotment. Several borings have been made recently, but these have not been sufficiently good to warrant sinking. The Middle, a new producer, was equipped with surface rig about mid-summer, and is giving a splendid account of itself in a weekly yield of 250 tons of 45% zinc ore. The Grotkin is now being developed; the ore will be trammed underground with gasoline locomotives to the Bull Moose mill. The Hird mine No. 3, known locally as the Bearcat mine, is a recent acquisition to the producers the Frontier Co. is now operating, and is yielding 200 tons of 25 to 30% zinc ore weekly.

In a recent interview the general manager expressed the belief that the grade of ore will improve as the lode is followed into the hanging wall, the mine having been opened back of the foot-wall. The Hird mine No. 4 is being permitted to rest, pending more favorable conditions for working low-grade ore. The company is engaged with drill squads on the Treganza, Jim Calvert, Robson, and Rundy leaseholds, in the Benton district, on the Grotkin at Leadmine, and at the Merry Widow mine and Virtue and Kneebone leases in the Galena section. Labor conditions are pronounced adequate, but many of the more skillful men are now in the United States army.—J. H. Billingsley advises that following the snowstorm that was general over the field recently, all teaming was abandoned for a whole week, the snow being 10 ft. deep on the east and west roads. Complaint was made that no assistance was rendered by local authorities, though mining companies pay thousands of dollars in taxes annually. On account of the blockade the Frontier company carried over at the week ended January 12 more than 1000 tons of milled ore. Electric-power service has been good considering the fierce battle raged against the elements. On the Hughlett and Kneebone leases it is said promising prospects have been proved by drilling.—A new mining company with a capital of \$100,000 has been organized under the laws of Illinois at Galena; it will be known as the Blewett Mining Co. A large body of zinc ore has been developed on this land, one-half mile south of the city of Galena, Illinois. Work has been started on a new shaft and a mill-building is planned just as quickly as the ground has been opened. The board of directors for the first year are E. Blewett, W. Westwick, C. Moores, R. I. McKee, and J. H. Billingsley.

TORONTO, ONTARIO

GOVERNMENT SHIP-BUILDING PLANS.—DOME MINES.—KIRKLAND LAKE.—BOSTON CREEK.—NIPISSING.

The Canadian government has announced a plan for national steel-ship construction on an extensive scale, involving an expenditure of between \$50,000,000 and \$60,000,000 per annum. It is proposed to utilize to its full extent the capacity of existing shipyards, where a large number of ships are now being constructed both for the British government and foreign registry. After these contracts are completed no further ship-building for registry abroad will be allowed until the end of the War, or for some time thereafter, and all construction will be done by the Government. Charles Duguid, naval architect for the Government, who has had a lengthened practical experience in British shipyards, will be in charge. An important feature of the plan is the establishment of rolling-mills for the production of steel plates and shapes, which cannot at present be secured in any quantity from the United States, owing to the pressing domestic demand. These rolling-mills will be started in connection with the steel plants at Sydney and New Glasgow, Nova Scotia, Sault Ste. Marie, Ontario, and possibly at other places. The maximum capacity of the shipyards to be taken over is estimated at 300,000 tons per annum. The shortage of steel, caused by the great demands of the munition plants, which are now receiving orders to the value of \$30,000,000 per month, is severely felt by the railroads, which are badly in need of supplies of rails for track maintenance.—The Canadian Railway War Board, a recently constituted body representing the principal railroad companies, organized with the object of meeting the emergencies created by the War, has decided that it would be advisable, in view of the impossibility of obtaining rails otherwise, to tear up 1500 or 2000 miles of the less important lines, and use the rails for the requirements of the main arteries of traffic. This under present conditions is a somewhat large order, as it is estimated that 20,000 laborers would be required for the work with none at present in sight. The Railway War Board has therefore recommended

that the Government secure Chinese labor, by detaining the coolies who are passing through Canada to work on the western front overseas. This proposal is, of course, strongly condemned by the labor unions, and is hardly likely to be entertained by the Government. The labor shortage is steadily growing more serious, affecting all lines of industry; and all sorts of propositions and suggestions as to a remedy are being mooted, that finding the greatest favor being the industrial conscription of aliens, enemy or otherwise, for use in the essential industries at mere subsistence wages. In view of the reported intentions of the Government to take drastic measures in this direction, Premier Borden has issued a statement that all such rumors are unfounded, as the Administration has not as yet even considered the question, though it will take the matter up in the near future. In the meantime Hon. G. D. Robertson has been commissioned to visit the steel and coal plants at Sydney, Nova Scotia, where the output is being considerably curtailed by the shortage of workers, and report on the labor situation there.

Preparations are being made for renewed activity at the Dome Mines, Porcupine; a contract having been let to the Longyear company for sinking the main shaft from the present depth of 1000 ft. to the 1500-ft. level.—The shaft on the Jupiter property of the McIntyre has reached the 1000-ft. level and driving has been started to connect this working with the drift being run from the McIntyre shaft at 1940 ft. distance, along the principal orebody, which is in some places 50 ft. wide. The orebody is stated to have been proved to a depth of 1350 ft. with gold content at that depth averaging \$20 per ton.—At the Davidson, a good body of high-grade ore five to six feet wide and 2000 ft. long has been opened on the 100-ft. level. The new mill is expected to be ready for operation early in February.—Operations on the Schumacher are yielding satisfactory results. A vein has been cut at the 300-ft. level, which is stated to assay \$8 per ton over a width of four feet. Extensive sampling is being done at the West Dome on behalf of Montreal interests. A mill-run of 1000 tons of West Dome ore will be made at the Dome Lake mill.—The Kirkland Lake mine has been closed on account of severe weather, and will not be re-opened until spring.—The Wright-Harveys mine has installed new machinery, including a 200-hp. motor, and 12-drill compressors, and is actively pushing development. The shaft of the Teck-Hughes is down to the 500-ft. level, where a large ore-crusher will be placed.—Activity in the Boston Creek district is steadily increasing, the three most promising properties being the Patricia, Miller Independence, and Mondeau. At the Patricia high-grade ore has been proved to continue below the 100-ft. level, and the outlook is highly satisfactory.—The mill of the Miller Independence has been closed until spring, but development is being pushed in the mine. The main shaft is to be continued to 150 ft.—The Mondeau has installed a new steam mining plant.

During December the Nipissing produced ore of an estimated value of \$340,793, and shipped bullion from its own and custom ores of a net value of \$376,423. Shaft No. 63, which has been idle for two years, is being unwatered for a resumption of operations. New exploration work by means of diamond-drilling will shortly be undertaken.—The Trethewey has purchased a controlling interest in the Castle Mining Co., taking over 51% of the stock of \$1,500,000 at 20c. per share. The Castle holdings are adjacent to the Miller Lake-O'Brien of Gowanda.—The Kerr Lake produced 203,048 oz. of silver during December, as against 205,522 oz. in November. The total production for 1917 was 2,599,525 oz. as compared with 2,545,804 in 1916. The payment of its last dividend of 5% will bring its total returns to shareholders up to \$7,410,000.

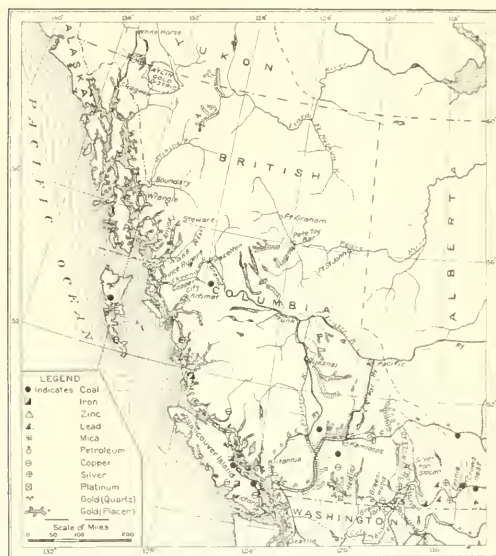

The Canadian government has modified the embargo placed on the export of molybdenum and tungsten, and will permit the shipment of these ores under license to approved consignees in the United States and France. This action is likely

to have a stimulating effect on molybdenum mining in Ontario and Quebec, both of which provinces have extensive deposits of this metal. The embargo considerably curtailed the output, as the producers were practically confined to the British market at prices fixed by the Imperial government, which were a good deal lower than could have been obtained in the open market.

VANCOUVER, BRITISH COLUMBIA

THE BRITANNIA.—GRANBY CONSOLIDATED.

During the year 1917 the Britannia Mines on Howe sound produced 18,000,000 lb. of copper, 92,000 oz. of silver, and 900 oz. of gold; a slight improvement on 1916. With the close of the year the general programme of construction was completed, December witnessing the first operation of the new power supply. Now 2000 tons of ore is being treated daily, an increase of 1200 tons over the capacity of the old mill. The oil-

BRITISH COLUMBIA, SHOWING BRITANNIA AND ANYX MINES

flotation process is entirely satisfactory and is giving an excellent recovery. Production was interrupted by power shortage in the early summer, the result of a lighter rainfall than usual, but the completion of the new power-plant ensures an adequate supply of power during 1918. The installation of this system necessitated the building of a dam on the south fork of Furry creek; from there the water is piped 18,000 ft. to the beach power-house. This work cost \$500,000, but a maximum of 4000 hp. and an average of 2000 hp. is provided and the use of fuel thus avoided. The steam plant has been retained as an emergency power plant. A new steamer was bought during the year and 12 storage-battery locomotives were added to the mill equipment. The usual amount of driving and cross-cutting was carried on in the mine and a number of new strikes were made. At the beginning of 1918 the company's ore-reserve is greater than it was a year ago. Plans for the future provide for the continuance of the general policy of development and progress, which was laid down by the late G. B. Schley, who was the president and principal stockholder of the company, and it was due to his faith in the future of the mine that the present success has been reached. The work

at Britannia is in charge of J. W. D. Moodie, vice-president and general manager. E. J. Donohue is secretary-treasurer, and C. P. Browning is general superintendent. During the year the company paid out \$1,500,000 in wages and \$2,500,000 for supplies. Additional accommodation has been provided for the employees in the form of three new boarding-houses at the top of the hill, which are heated by steam and equipped with baths. There is also a recreation hall where moving pictures are shown.

Already the largest copper mining and smelting company in the British Empire, the Granby Consolidated Mining, Smelting & Power Co., expects to have its new converters at Anxoy ready for work by the end of February, which will increase the capacity of the plant from 75,000 to 85,000 tons per month. At present, owing to the lack of sufficient converter capacity, the copper matte has to be run through the furnaces a second time; the first operation gives a 12% matte, which is raised to 25% by the second treatment. Another improvement that is being made at the Anxoy plant is the construction of by-product ovens that will produce 350 tons of coke daily from about 500 tons of coal. Machinery for this plant has been ordered, and will entail an expenditure of \$1,500,000. All the building material and structural steel will be bought at Vancouver as well as whatever other supplies the city can provide. The company spends some \$3,500,000 in Vancouver every year for the regular supplies, so that the construction of the coke plant will mean a large extra expenditure here. To supply coal for the ovens the company recently acquired some coal areas on Vancouver island. Diamond-drilling and other development is now in progress there and it is expected that the property will be ready to ship coal by the middle of 1918. About a thousand tons per day will be mined, half of which will be used at the coke plant and half sold in the open market. A steam-power plant using fuel oil has been erected on Granby bay, where the smelter is situated. The plant includes blast-furnaces and converters, and a sintering plant has just been added. Besides the mines at Phoenix and Hidden Creek the company owns properties in Alaska and at several points along the coast of British Columbia. Its earnings at the present time are between 20 and 30% on the capital stock; dividends at the rate of 10% are being paid and \$7,148,056 or more than 50% on the capital stock has so far been paid in dividends. The value of the ore-reserves is estimated at \$125,000,000.—The Granby company established a new record at its Anxoy plant in December. The production in that month was 3,549,310 lb. of copper, as contrasted with 3,159,284 lb. in May of that year, the banner month up to that time. The total production in 1917 was 40,314,786 lb., of which 7,067,850 lb. was from Grand Forks. This may be compared with a total of 13,710,605 lb. from Grand Forks in 1916.

The Victoria & Island Development Association of Victoria is campaigning energetically for an iron and steel industry on this coast. In a number of places in this Province there are extensive deposits of high-grade magnetite, which, together with the enormous amount of water-power that at present is going to waste, should form the nucleus for a large iron and steel industry.

HOUGHTON, MICHIGAN

UNUSUAL. WEATHER.—MINERALS SEPARATION.—MASS CON.—CHEROKEE.—SENECA.

For the first time in 18 years the copper country of Michigan has been shut off from the outside world as far as railway service is concerned. Climatic conditions here are not unusual, looked upon from the standpoint of the local resident, although December and January thus far have been a little colder than usual and the snowfall has been larger than any in past records of the Government office. But this is the first time that no trains have come in from Chicago or Detroit and none has departed. Despite these unusual conditions not a

stamp-mill has shut-down. Local railway service has been regular and every mine is supplying its mills with plenty of copper ore for concentration. Local railways are accustomed to handling unusual conditions and have kept the main lines and shaft side-tracks well open all the time. So that this necessary war munition, copper, is likely to be produced during January 1918 at a better rate than in any month for three years.

While there is hope that the flotation process of the Minerals Separation Co. may be applicable to the amygdaloid lodes of the Michigan copper country there really is not much reason for expecting that any large sums will be realized from its practical operation on such sands. Long continued experiments by the Calumet & Hecla interests on their conglomerate sands showed successful results, but on the Osceola sand no such results were secured. Ultimately the Calumet & Hecla will treat all of its conglomerate slime by the flotation process. This includes the slime from the mill-operation as well as the slime from the sand pile, from the lake, and even the slime treated by leaching. It is impossible as yet to give figures on the profits accruing therefrom.—At the White Pine property there are two classifications of the tailing that will be treated by the flotation process. One is the regular slime and the other a grade of light and flaky copper that ordinarily is not saved, but that is caught by flotation. A 50-ton plant was used for an experimental period and now a 600-ton plant is in operation. No other mines in this district have experimented with the process and while some of the concentration experts are planning to try the scheme they are frankly dubious as to its success.

Mass Consolidated is maintaining ore shipments close to 1000 tons per day and today is in a better general physical condition than ever before. Practically all of its underground improvements, with the exception of the motor haulage, have been finished. Of course the elaborate plans for B shaft have not been carried out because the outlay at this time would be too great, and Mass is one of the properties of comparatively limited tonnage and low-grade ore that finds it possible to produce copper at the Government's price only by the best management and the exercise of the greatest economy.—Resumption of operations at the Cherokee can be anticipated when conditions are improved. Suspension was not due to any lack of mineralization in the ground opened or lack of faith in the ground yet to be opened but rather to the difficulties to be found in a small exploration property so far distant from Houghton at this time of the year. The ore taken out and sold ran 87 lb. per ton, an unusual showing, even for selected material. Practically every cross-cut showed ore that offered possibilities for commercial operation.—Work at Seneca was started last spring. It is hoped that hoisting of ore from the shaft will commence next week. While to some this may seem a long time to get a property in shape to commence production, and while it does not indicate that the early promise of getting to the Kearsarge lode and stamping ore in two years is likely to be successful, it must be remembered that unusual hindrances have delayed the work. In addition to the great difficulty in securing even the ordinary mining machinery, building a railroad extension and all the surface buildings, have been carried on under circumstances which were discouraging, to say the least. Plans for the sinking of the shaft with unusual rapidity, upon a new system and by expert shaft-sinkers, promise, now that the shaft-house has been covered in, a burst of speed that will make all former records look insignificant by comparison.—Illustrative of the difficulties that some of the smaller and leaner properties have to encounter, the Franklin now is employing 30 trammers, where formerly they used 120. Fortunately the difficulty does not interfere quite as seriously as one might suppose with the output of ore because the management has a rope-haulage tramming system.

THE MINING SUMMARY

ALABAMA

CLAY COUNTY

(Special Correspondence.)—The Crystalline Flake Graphite Co., Ashland, is erecting a mill in which to concentrate its graphite, and it is expected that it will be in operation by March 15. Part of the equipment has been ordered from the Denver Quartz Mill & Crusher Co., and includes that company's No. 2 mill. R. E. Meade & Co. of Ashland have charge of the construction.

Ashland, January 19.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—The Dos Cabezas Gold Ridge Mining Co., has decided to erect a 100-ton mill. Considerable development has been done on the property, the ore-reserve being estimated sufficient to supply the proposed mill for 10 years. The Commonwealth mine has been sub-leased. New development work is yielding five tons of ore per month which is being shipped to Douglas. The old tailing is being re-worked and as soon as a new engine is in place the mill will be running to capacity.

Bisbee, January 20.

GILA COUNTY

(Special Correspondence.)—The New Dominion Copper Co. has again been granted permission, by the Arizona Corporation Commission, to sell stock. From the fine showing on the 800-ft. level the company has decided to sink to the 1200-ft. level and discontinue cross-cutting at the 800-ft. level.—High-grade hornite ore, carrying silver, has been opened while cutting the station on the 1000-ft. level of the Iron Cap mine. The cross-cutting which has been done on this level in making the station shows the ore to be at least 10 ft. wide; it assays 12½% copper.—The last 285 ft. of the shaft, being sunk by the Porphyry Copper Co., has been in ore. The company plans to drive at the 530 and 630-ft. levels to the Inspiration boundary on the east and to the western boundary. For 85 ft. below the 475-ft. level good chalcocite ore was cut in the shaft. At the 640-ft. level good ore was again struck.

Globe, January 19.

During last year the Mazatzal Mining Co. did 1600 ft. of development consisting of 1660 ft. of adits, a winze, and several prospecting shafts. Besides this some three miles of road was graded. The mine is situated 16 miles west of Payson, and consists of eighty 20-acre claims. A 15-ft. vein has been opened at a number of points by adits and surface shafts, and two small veins, running as high as \$125 in silver and copper, have been cut in one of the adits.

GREENLEE COUNTY

(Special Correspondence.)—The Carlisle Mining Co. has surrendered the property to G. E. Utter from whom it was purchased three years ago. It is understood that Mr. Utter will continue to operate the property.

Clifton, January 18.

MOHAVE COUNTY

(Special Correspondence.)—Developments at the Oatman

United are encouraging. The cross-cut east toward the Rhyolite Dyke is in 460 ft. The west cross-cut is in 550 ft. at which point a 12-ft. vein was cut.—Development work on the 400-ft. level of the Gray Eagle claim of the Tom Reed has opened two ore-shoots, each 160 ft. long, averaging respectively \$14 and \$16 per ton. These ore-shoots are separated by a 55-ft. barren zone.—F. T. Torpey, of the Gold Road Bonanza, and associates have purchased the Gold Range property.—The McCracken Silver Lead Mining Co. has driven its adit to the big vein; driving under the ore-shoot exposed at the surface will be started.—The main shaft on the Leviathan mine has reached a depth of 250 ft., where a station will be cut and a cross-cut run to open both veins. A fire occurred in the mill, causing considerable damage, but the delay of a few days only is expected.—The Schuylkill Mining Co., has purchased all of the electrical equipment of the Golconda and is erecting it at the Tennessee mine.

Kingman, January 19.

PIMA COUNTY

(Special Correspondence.)—The new three-compartment shaft on the Southern claim of the New Cornelia is now down 35 ft. Ore was found practically from the surface.

Tucson, January 18.

YAVAPAI COUNTY

(Special Correspondence.)—At a meeting of the directors of the Green Monster it has been agreed to start development work at the old Brookshire workings.—The unwatering of the Storm Cloud mines, near Senator, is completed. The O'Brien Mines Syndicate is arranging to operate the mine.—A gold strike was made recently at the bottom of the 40-ft. shaft on the Blue Jacket gold mine on Lynx creek. The ore-shoot is said to be 12 in. wide and assays \$88 per ton.—The holdings of the Arizona Portland company in Copper basin have been sold to the International Syndicate of Mines & Smelters. Two shifts are now at work, machinery has been ordered, a complete electric equipment is to be installed, and all necessary camp buildings erected.—The United Arizona Copper Co., in the Copper Creek district, has cut a body of molybdenite ore on the 620-ft. level. It is claimed that the orebody is 17 ft. wide running as high as 2½% molybdenite; 12 inches on the foot-wall runs 30%.

Prescott, January 12.

(Special Correspondence.)—The working adit of the Arizona Daisy, driven on the Daisy Dell vein, is now in 455 ft. Surveys show that the face is near the rich shoot of ore discovered in the shaft some years ago. The adit opened two other ore-shoots.—A new vein of copper sulphide ore has been cut in the winze from the 600-ft. level on the Calumet & Jerome Copper Co. It is reported that a 6-ft. vein of lead copper-silver ore, valued at \$100 per ton, has been uncovered at the 200-ft. level.—Messrs. Elmer and Warren recently located an old property three miles south of Prescott on which a large body of 8% vanadium ore has been found.—The Copper Chief gold mine is expected to be operating at full capacity of 100 tons per day within a short time. The mill is at present treating 60 tons of ore per day, all of which comes from the oxidized zone above the 220-ft. level. On the Wonder-

ful claim a shaft has been sunk to the 100-ft. level and 250 ft. of cross-cutting driven.—The Consolidated Arizona Smelting Co. is measuring its ore-reserve. The smelter is being enlarged and when completed will have a capacity of 2,500,000 lb. of copper per month.—The 11 patented claims of the Yeager Canyon Copper Co. have been purchased by the Shannon Copper Co., for a consideration that is said to be \$75,000.—The Locey Fabst Gold Mines Co. has resumed operations after a 60 days shut-down, awaiting electric equipment. It is announced that there is sufficient tonnage now developed to keep a 100-ton mill, which is to be erected at once, in operation.

Prescott, January 19.

YUMA COUNTY

(Special Correspondence).—The greater Ajo Copper Co., which owns 68 claims in the Palomas district, has been purchased by a New York syndicate.—At a depth of 70 ft., in the inclined shaft of the Vindicator lease in the Salome-Wendon district, two feet of high-grade copper sulphide, running 25 to 35% copper and \$10 gold, has been opened. Two carloads of ore have been shipped from this shaft.—The lessees on the Bullard property are shipping high-grade copper glance.—The Black Reef has opened some good sulphide ore on the 300-ft. level. The drilling rig for testing the property of the Arizona Standard Copper Co. is now on the ground and drilling will commence immediately.

Yuma, January 18.

CALIFORNIA

BUTTE COUNTY

(Special Correspondence).—High-grade ore has been uncovered near the bottom of the shaft of the Bumble Bee mine, in Morris ravine, and development is being conducted to determine its extent. The shaft is 400 ft. deep and development of the mine has been steadily proceeding since B. T. Hickman and Charles C. Vaughn acquired control. It is planned to operate the nearby Josephine property shortly. Both mines are near the Banner group.—Richard Phillips and New York associates have resumed work on the Banner group. The Banner is being placed in shape for extensive work, and the Amoskey mine has been unwatered and is undergoing repairs. Good ore was exposed in the Banner mine last summer, and sufficient capital is stated to be available for development at greater depth.

Oroville, January 27.

KERN COUNTY

(Special Correspondence).—Work in the south face of the main cut at the Yellow Aster has uncovered ore buried by the great slide of 1914, and the old mill is again in operation, pending the completion of the new plant. The old mill has been idle about ten weeks owing to lack of profitable ore. In the new plant, which will have double the capacity of the old mill, the coarse product will be eliminated by screening and the fine ore, containing practically all the gold, will be fed directly to the stamps. The company is contemplating mining its huge bodies of low-grade ore by steam shovels, or a cable-way excavator, and may discard the stamp-mill in favor of a set of ball-mills. The management is stripping the main deposit, but is hampered by lack of labor and high cost of materials.—Tungsten mining is claiming considerable attention in this field, and numerous properties are being prospected. The sharp decline of tungsten prices a year ago checked development of many promising deposits, but the outlook is favorable for an active summer.

Randsburg, January 26.

MARIPOSA COUNTY

(Special Correspondence).—The Ruth Pierce mill is running full time; 35 men are employed. Considerable trouble with high-graders has been experienced this summer; \$4000 in high-

grade ore has been taken from caches made by Hungarian workmen.—The Mount Gaines property is being cleaned up and made ready for a force of men. A 100-hp. electric hoist is being installed.—The Mariposa grant dam has been restored to normal condition at Bagby, and the ore from the Queen Specimen is being milled at the Bagby plant. It is understood that the payment due this month has not been made and that the grant has reverted to the Mariposa Commercial Company.—The Clearing House property is working full time, and the mill is running when conditions permit. The water in the Merced river has never been so low as it is now. This necessitates some shut-downs. The Mountain King is preparing to sink 600 ft. from the 1400-ft. level. The mill is running full time. The White Oak mine has installed electric equipment, and has completed the new shaft-work. A pole-line to connect the mine with the Kittridge plant of the San Joaquin Power Corp. is being put in. The work at the Castenetto mine is progressing slowly.

The White Gulch Mining Co., operating the Virginia mine, had considerable trouble with water on the 700-ft. level. A new large station pump is keeping the level clear. Until this fall the property has had considerable trouble getting sufficient water for operations. Conditions now are just the reverse. The Grey Eagle bond has expired and there is some litigation in prospect on the property. The Champion mine has added an electric equipment. The power company has expended a considerable sum taking the power from White's gulch to Coulterville and to the Champion mine.

A great deal of prospecting is going on throughout the county. It has been hampered, however, by lack of water. New prospects in Devils gulch and Sherlock gulch and in the Hite's Cove district on the East Belt are being made ready for operation. Labor, of a sort, is plentiful.

Bagby, January 20.

SAN BERNARDINO COUNTY

(Special Correspondence).—The Tom Reed Gold Mines Co. and Clipper Mountain Gold Mines Co. have joined forces in driving a cross-cut from the 300-ft. level of the Clipper Mountain mine, Gold Reef district, to intersect the orebody. Powerful pumps have been installed, a large force of men set at work, and within three weeks R. B. Kepner, the manager, expects to intersect the foot-wall of the vein. On surface the vein is 40 ft. wide and assays \$4 in gold. Both companies originally planned to sink their respective shafts to a depth of 500 ft., but at 300 ft. a heavy flow of water seriously hampered work.—Arrangements have been made for vigorous development of the Black Hawk gold property, 36 miles east of Victorville. The orebody is 30 ft. wide and assays \$1. The mine was first worked in 1887 and a 10-stamp mill later erected, but the low-grade ore failed to yield profits. It is now controlled by the Merger Mines Co. of New York.

San Bernardino, January 27.

SHASTA COUNTY

(Special Correspondence).—The Mammoth Copper Co., which recently took a bond on the Keystone mine midway between the Stowell and Balaklala mines, has struck a fine body of copper ore at the bottom of the 260-ft. shaft.—A two-stamp mill has been erected at the Yankee John mine, four miles west of Redding. It will be started up about February 1. T. E. Graff is superintendent of the mine and mill.

Redding, January 21.

(Special Correspondence).—The Mammoth Copper Co. has transferred all its property at Kennett and vicinity to the parent corporation, the United States Smelting, Refining & Mining Co. The Mammoth company has ceased to exist; the purchasing branch of the smelting company is known as the United States Stores Company.

Redding, January 25.

COLORADO

DENVER COUNTY

A number of well-known Denver and Colorado business men have been carrying on investigations as to the possibilities of the Colorado shale fields as a source of oil supply. These investigations have extended over a period of some two years, and have been so satisfactory that the investigators have organized the American Mineral Oil Co., which is headed by H. M. Roeschlaub and backed by a board of directors of well-known business men. The company has acquired some 1400 acres of shale lands, and has under consideration a contract for the erection of a plant.

MINERAL COUNTY

(Special Correspondence.)—The Creede Quintette property at Sunnyside, which is being operated under lease by A. M. Collins, is rapidly developing into a bonanza. Shipments amounting to about 600 tons per month of 100-oz. silver ore are being made and the owners of adjoining property are threatening to start an apex suit. The success of the Quintette has stimulated interest in other properties in the Sunnyside section and considerable prospecting is being done.—The Creede Exploration Co., which holds a lease on most of the Amethyst vein below the level of the Nelson tunnel, has unwatered the Berkshire shaft on the Amethyst property and is driving both ways. A good grade of milling ore has been struck in the north drift. The Commodore shaft is being unwatered also and as soon as this is completed drifts will be run from it. This company also holds a lease on the Solomon property on East Willow creek and is sinking several winzes, one of which is reported to have struck high-grade galena.—Lessees are making small shipments from the Bachelor, Commodore, and Last Chance-Del Monte properties on the Amethyst vein.—A small amount of milling-ore is being extracted from the Happy Thought by the Creede United Co. and treated in the Humphreys mill.—Some small shipments have been made from the Holy Moses by lessees.—Shipments of fluorspar from the Wagon Wheel Gap mine amount to 2000 tons per month.

Creede, January 20.

SAN JUAN COUNTY

(Special Correspondence.)—For the first time in many years the mines that made Red Mountain famous, the Yankee Girl, Genesee-Vanderbilt, and other properties, now under lease to the Red Mountain Mines Co., are being operated during the winter. The winter work consists chiefly in getting the mines into shape to make a large production when the railroad starts running next spring.—Louis Schafer and associates are erecting an electric hoist on the St. Paul, near Red Mountain, which they have under lease.—John H. Slattery is successfully mining, under leases, the Highland Mary, Gold King, North Star on Sultan, and Detroit Colorado properties. He is also manager of the S. D. & G. Leasing Co. which operates a number of small leases.—The Copper King mine has been leased with a five-year bond.—The Coming Wonder on Anvil mountain is now being operated by a syndicate of local men who have bought the lease from Jackson & Anderson. Ore is being extracted from the old adit, while a new one is being driven at a lower level. The property is equipped with a tram that makes shipments all the year round possible. Edward Johnson is superintendent.—The Zuni mine on Anvil mountain has been leased to Jackson & Anderson who expect to start work soon. This was one of the early-day shippers of the district, but there has been no work done on it for several years.—The Champion property on Sultan mountain is being prospected with a diamond-drill for possible parallel veins.—The Lackawanna, on which operations were suspended a few weeks ago, will be started again. The tram to the railroad will be

completed and the milling ore shipped by rail to the Little Dora mill for treatment.—The Peerless San Juan is working a small force in the mine. Delay in receiving machinery has prevented the completion of the repairs to the mill.—The changes in the Hamlet mill have been completed and work has been re-started.—The Durango smelter is adding additional roasting capacity to take care of the increased tonnage it is receiving from this and neighboring districts.—The Sunnyside Mines Co. is making fair progress with the construction of the crusher plant at the mine and the 500-ton flotation plant at Eureka.

Silverton, January 20.

TELLER COUNTY

(Special Correspondence.)—The report of Kenneth MacKenzie, president and general manager for the Acacla Gold Mining Co., shows a balance on January 1 of \$17,608, a gain for the year of \$3103 in addition to payment for sinking the shaft from the 100 to the 1450-ft. level and other development work and improvements to mine plant. The receipts for last year totalled \$28,053 and expenditures \$24,249.—The executive committee of the Cripple Creek Deep Drainage & Tunnel Co. has under consideration an increase of the working force to two shifts, both in the heading and Cresson cross-cut. The heading of the Roosevelt tunnel is now east of the Rose Nicol shaft and near to western boundary line of the Portland Gold Mining Co. A vein recently cut on the Rose Nicol Gold ground has assayed as high as \$16 per ton.—The Excelsior Mining, Milling & Electric Co. is cutting a station at 600 ft. in the Llewellyn shaft on the Longfellow, and when this is completed shipments will be moving from this Stratton estate property on the south-eastern slope of Bull hill.—The Stratton estate management has sold the dump at the Abe Lincoln mine in Poverty gulch to Pfeiffer, Murphy & Kinsey of Cripple Creek, who have contracted to move it. The ore will be shipped to the Independence mill of the Portland Gold Mining Co. near Victor; samples taken indicate an average value of \$5 per ton.—Three sets of lessees are engaged on the Lee and Empire State dumps of the Isabella Mines Co. and shipments are leaving the Bull Hill loading station at the rate of three cars, or about 100 tons, per week. The ore is being treated at the mill of the Golden Cycle Mining & Reduction Co. at Colorado Springs and is returning from \$8 to \$13 per ton.—A special meeting of the stockholders of the Hondo Gold Mining & Milling Co. has been called for January 28, to act upon a proposition to dissolve the company. The Hondo company has been operating the properties of the Keystone Gold Mining Co. under bond and lease at a loss.—The Cripple Creek district will be represented at the annual meeting of the Colorado Metal Mining Association to be held in connection with the meeting of the Colorado Chapter of the American Mining Congress, at Denver, by Thomas B. Crow, H. L. Shepherd, L. G. Carlton, M. J. McCarthy, Charles Walker, W. E. Ryan, H. P. Nagel Jr., C. D. Guernsey, and E. P. Arthur Jr. The opening session will be held on January 22 at the State house.

Cripple Creek, January 21.

IDAHO

SHOSHONE COUNTY

A corporation that probably will be known at the Sunshine Consolidated Mining Co. has been formed by representatives of the Sunshine Mining Co., Tuscumbia Mining Co., Parrot Mining Co., Toughnut Mining Co., and Idora Mining Co., as the result of a meeting of representatives held in the office of the Idora company on January 17. The Day family of Wallace, large operators in the Cœur d'Alene region, are identified with three of the corporations. E. G. Ellis of Missoula, Montana, is a director of the Sunshine, and Whaley brothers and Mays of Missoula are the principal owners of the Tuscumbia.

Dan L. McGrath is directing the development of some of the properties. James C. Broad and C. E. Mallette of Spokane are identified with the Idora. The promoters will furnish funds for the enterprise, which includes the advance of an adit from which all of the mines can be penetrated at more than twice the present depth. The agreement was made subject to ratification by the stockholders of the respective companies.

The Sunshine Mining Co., which now has a capital of 1,500,000 shares, is to increase its capital to 2,500,000 shares, and all stock held by its stockholders is to be turned back into the treasury of the company. The 2,500,000 shares are then to be divided in equal amounts to 350,000 shares each among the five companies mentioned, leaving 750,000 shares in the treasury of the Sunshine company. The promoters of the consolidation agree to take 80,000 shares of the stock allotted to the Idora company and pay \$40,000, to be used to pay the present indebtedness of the company. This would leave 270,000 shares of the stock of the consolidated company to be divided among the present stockholders of the Idora company. The amount of stock of the Idora company outstanding is 1,200,000 shares, which would give each stockholder one share of the Consolidated stock for practically four and a half shares of his Idora stock. The five properties form a compact group of 25 or more claims on Beaver creek in the Coeur d'Alene region. Two veins, known as the Tuscumbia and the Idora, traverse the group on parallel lines at points about 300 ft. apart. It is proposed to advance an adit between the veins and cross-cut from it into the several properties at a maximum depth of 1200 to 1300 ft. An adit that may be used for this purpose has been started. Ore has been exposed in all of the mines at depths ranging from 300 to 500 ft., so the greater corporation would have something tangible upon which to proceed in its development at depth.

The Hecla Mining Co. declared a dividend of 5c. per share, \$50,000, on January 20, bringing the total disbursed to date to \$6,955,000.—The Caledonia Mining Co. has declared its regular monthly dividend amounting to \$78,150, payable on February 5. This brings the total disbursements to \$2,991,641.—The 200-ton plant of the Spokane Metals Recovery Co., on Nine Mile creek, $\frac{3}{4}$ miles from Wallace, is nearly completed. The plant is situated below the Rex dump, and is in a position to receive mineral from the creek that flows from the Interstate-Callahan, Success, and Rex properties. The settling tank measures 30 by 30 by 8 ft. The equipment includes a flotation system and tables. The water of the creek and its mineral content will be conveyed to the plant by a flume 500 ft. long. C. L. Hewett, mining engineer, is president and manager of the company. M. H. Eggleston vice-president, David Holzman treasurer, and H. W. Ingalls assistant secretary. The production in this county, embracing the Coeur d'Alene region, was \$51,717,573 in 1917, as compared with \$44,311,204 in 1916. The figures for 1917 follow:

Lead lb.	380,950,000	\$33,474,077
Zinc, lb.	93,100,000	\$127,630
Copper, lb.	1,423,600	386,497
Silver, oz.	11,875,000	9,647,369
Gold, oz.	4,100	82,000

These figures are based on the average price of the metals for the year.

MONTANA

LEWIS AND CLARK COUNTY

(Special Correspondence.)—The Helena mining district is more than usually active. New mines are being developed and old properties are being unwatered and prepared for active working. Among these is the Lee Mountain at Rimini. Two shafts are to be sunk below the lower adit-level. The power is to be acquired from the Valley Forge plant on the east side of Ten Mile creek. The Lee Mountain has produced a large

tonnage in silver-lead ore. The Bullion King in the Park district, Broadwater county, has been taken over by new men and has been unwatered to the bottom of the old workings, which were down 180 ft. The shaft is to be sunk to the 250-ft. level. In Lump gulch the Liverpool mine has been bought and is to be immediately unwatered. The Amalgamated Silver Mines Co. is sinking the Free Coinage shaft No. 2 down to the 250-ft. station. The old shaft is 180 ft. deep and has been re timbered. The Mountain States silver-lead mine on Warm springs is also being unwatered to the 150-ft. level. The Cruse Developing Co., in Scratch Gravel hills, is stopping ore for shipment from the 640-ft. level east of the shaft. The Cruse Con. and Rock Rose management has decided to sink a shaft 1000 ft. on the Looby, Grass Valley district.

Helena, January 19.

SILVER BOW COUNTY

(Special Correspondence.)—The Davis-Daly Copper Co. has added an Ingersoll-Rand electrically-driven air-compressor, having a free-air capacity of 2800 cu. ft. per minute, to its equipment. The Colorado mine is sending 200 tons of high-grade ore per day to the East Butte smelter. The Hibernian is sending 100 tons of ore per day to the Washoe smelter.—The Butte Bullwhacker Copper Co. has elected the following officers for the year: A. Frank, president; H. I. Wilson, vice-president; H. Frank, secretary; D. J. Fitzgerald, treasurer.—The Barnes-King Development Co. declared a dividend of 10c. per share, \$10,000, payable February 15, to stock of record January 25.—The December earnings were between \$75,000 and \$80,000. Development work is progressing on the Shannon property, and the orebodies are holding up well.

Butte, January 20.

NEVADA

CLARK COUNTY

(Special Correspondence.)—The Boss Gold Mining Co. has increased its quarterly dividend to three cents per share, the first disbursement under the new rate to be made February 10 to stockholders of record February 1. The company is shipping 200 tons of gold-silver-platinum ore per month to the Los Angeles plant of the Palau Metals Co. This product is stated to average nearly \$200 per ton. A new contract is under consideration for disposal of the copper ore to better advantage.—The Manganese Corporation is shipping steadily from extensive manganese deposits near Las Vegas, and late work has materially extended the ore-bearing area. The company is improving shipping facilities, preliminary to a heavier output.—F. H. Hamilton and associates of Los Angeles have acquired control of several manganese claims and are preparing for extensive work. Eastern steel mills have arranged to take all the ore that can be produced.

Goodsprings, January 21.

HUMBOLDT COUNTY

(Special Correspondence.)—Inability of the Nevada Short Line railway to handle a steady output of ore continues to hamper production in the Rochester field. The Rochester Merger, Rochester United, Nenzel Crown Point, and other companies are ready to ship to the Mammoth smelter, at Kennett, California, but the railroad will not be in shape for some time to transport ore. Plans for rehabilitation of the line are under consideration.—Tungsten production is again claiming attention near Mill City. The Mill City Tungsten Co. is shipping steadily to the Toulon mill, and has 23 men employed. Good ore is being opened at several points under management of Thomas Sutton.—The Nevada Humboldt Co. is increasing its working-force and shipping steadily.—At the Olson group development of an excellent orebody is proceeding and shipments are going out. Several small operators are developing promising territory and expect to ship soon.

Four eight-horse and ten-horse teams are steadily employed in transporting ore to Mill City from the neighboring mines. The ore occurs as scheelite. The Humboldt Consolidated Co. is doing extensive work at the La Toscha mine, in Wright's canyon. The orebody has been tapped at a depth of 1345 ft. below the outcrop and shows a width of six feet of milling ore. Of this a 30-in. shoot is stated to assay 17 oz. silver and \$10 gold per ton. The development consists of an adit, 3500 ft. long, and numerous drifts and cross-cuts. It is planned to erect a mill in the early summer.

Lovelock, January 19.

(Special Correspondence.)—An agreement has been entered into between the Nenzel Crown Point Mining Co. and the United States Smelting, Refining & Mining Co., whereby the latter company agrees to develop the Crown Point company's mine, build a suitable mill, and make such other improvements as may be required. The smelting company is to be reimbursed from the proceeds of the mine.

Rochester, January 25.

WASHOE COUNTY

(Special Correspondence.)—George Hiell, the lessee who recently made a rich strike on the old State Line mine on what is believed to be the extension of the No. 4 vein of the Nixon-Nevada, has done enough work on the vein to convince him that he has made a genuine find and he is now engaged in widening the adit and putting in a track. The last assays from the lowest workings show that the high-grade ore averages a little better than \$200 per ton, while the lower-grade product will run \$60.—At the Nixon-Nevada mine, work on the main cross-cut is proceeding steadily but it has not yet reached the big No. 4 vein which it will tap at a depth of over 800 ft. on its dip. For the last 100 ft. the ground has been heavily mineralized. Surface trenching is still under way and has developed good showings in six veins besides those that have been opened at depth by the main cross-cut.

Copperfield, January 19.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—An order has been placed by Socorro Mining & Milling Co. for a new double-drum electric hoist, with a capacity of 2200 ft. in depth. This will be the largest hoist in the district. The old hoist will be used during delivery.—Peterson and associates are developing the Iron Bar group. A cross-cut adit has been run in over 500 ft. and the owners expect to cut the contact within a month.—The Oaks Co. continues daily shipments from the various holdings. The ore recently cut in the Deep Down mine was opened during the week in the levels below.

Mogollon, January 22.

OKLAHOMA

OTTAWA COUNTY

The construction of the 300-ton concentrating plant of the Producers' Mining Co. will be started soon and pushed as much as possible to make up for lost time. The Producers' company some weeks ago purchased the lease on a 40-acre tract of the Mary Whitebird land, immediately north-east of Picher. One shaft is being sunk into ore on this tract. The principal value to the lease is contributed by the result of the test holes of which there were 20 that showed ore-faces extending from 45 to 70 ft. in thickness, and assaying from 6 to 30% lead and zinc. L. V. Hivick, of Oklahoma City, is president, George B. Rittenhouse is vice-president, T. R. H. Smith, also of Oklahoma City, is secretary-treasurer.

OREGON

JACKSON COUNTY

(Special Correspondence.)—L. H. Van Horn of Kirby and

associates have taken a lease and bond for two years on the Copper King copper mine in the Blue Ledge district, with the stipulation that work must begin at the mine within 60 days. The mine property consists of eight claims, or 160 acres.—The machinery for the State 200-ton limestone-fertilizer plant at Gold Hill has arrived from the East. The 7000-ft. aerial tramway at the Greenback mine has been dismantled and shipped to equip the plant, which will be operated by electric power. Contracts call for the completion of the plant by April 1. The Rogue River Public Service Corporation, operators of power plants at Gold Hill and Grants Pass, which went into the hands of a receiver last June, has gone into involuntary bankruptcy, with liabilities of \$650,000. Since the corporation's financial troubles last year most of its contracts have been taken over by the California-Oregon Power Co., with plants on Rogue and Klamath rivers.—Much progress is being made in the development and equipment of the cinabar mines in the Meadows and Lake Creek districts, north of Gold Hill, with a view to a record production in the coming year.

Gold Hill, January 26.

JOSEPHINE COUNTY

(Special Correspondence.)—George S. Barton is opening a new chromite deposit on the Waldo Corporation property that is giving considerable promise. Mr. Barton will operate continuously through the winter.

Grants Pass, January 20.

SOUTH DAKOTA

LAWRENCE COUNTY

The new power-plant of the Homestake Mining Co. was completed on December 27 and, after a few bitches, successfully started on the first day of the year. The plant consists of two 1000-k.v.a. generators, each driven by two Pelton impulse turbines; two sets of three 666-k.v.a. Westinghouse transformers; and two Allis-Chalmers motor generators. The water is delivered at the nozzles under a static head of 547 ft. The work was started last April and consisted of the building of two concrete dams, laying of 27,000 ft. of redwood-stave pipe, the driving of 5044 ft. of tunnel, the building of several bridges and trestles to carry the pipe, and the erection of an electric transmission line. The work was designed by F. G. Baum of San Francisco and carried out by A. L. Wilcox. About 120 men were employed daily during construction.

WASHINGTON

STEVENS COUNTY

The United Copper Mining Co., operating at Chewelah, shipped 2 carloads of crude ore and 11 carloads of concentrate in December.

Ore in a body three feet wide containing 52 oz. of silver and 15% copper has been followed 30 ft. north on the 1250-ft. level. Other levels have contained equally rich ore, but not in a body of this width. If the body proves to have a considerable length it will make a big addition to the value of the mine. The same shoot has been followed south of the shaft, but it is not so rich. Concentrate of a higher metallic content has been produced in the last 30 days of operation. This results from improvements to the mill. The silver content is 31.8 oz. per ton of concentrate, and the copper runs 16%, a gain of 6 oz. of silver and 6% copper. The plant is saving 92% of the copper, as compared with \$3 to \$4% before the installation, and 93% of the silver, as compared with \$5 to \$6%.

The Consolidated Mining & Smelting Co. has intimated its readiness to accept United Copper ore at the Trail smelter, beginning February 15. The previous destination of the product has been Tacoma. The number of men employed at the properties has been increased to 115. The outlook of the company for the current year is good. The entire property,

including both the United Copper and the Copper King, is being sampled and surveyed. The inquiry goes into all details of milling. The results of the survey and the sampling will be compiled for the benefit of the stockholders.

STEVENS COUNTY

The new tramway of the Northwest Magnesite Co. was placed in operation on January 22, and the first rock from the quarries, $5\frac{1}{2}$ miles distant, was received at the calcining plant, a mile south of Chewelah, during the day. The tramway has a capacity of 30 tons per hour, but this can be doubled by the addition of buckets. The Riblet Tramway Co. is installing transportation equipment for the Valley Magnesite Co. and the American Minerals Production Co. The Valley tramway will connect the quarries with the kilns, half a mile apart, and the American tramway will connect the quarries and kilns of the Red Marble quarry with the Spokane Valley & Northern railway, a mile away.

MEXICO

SONORA

(Special Correspondence).—E. P. Spalding, of New York, and associates have secured a lease on the semi-anthracite coal land of Carlos F. Johnson, which is about three miles north-east of Ortiz, and about 60 miles from Guaymas. The coal land covers an area of about 32 square miles. The development consists of three shafts, the deepest of which is 400 ft., and a number of prospect holes and also a bore hole at El Salto, which has a depth of 460 ft. and which cut through three seams of coal having a total indicated width of 35 feet. Extensive exploration by means of diamond-drills is now contemplated and arrangements will be made for the Southern Pacific of Mexico to build a 30-mile road to tap the field. The lease is said to be for 99 years with option to purchase at the end of five years for \$3,000,000. The contract calls for periodic payments to the owners who will also receive 15c. per ton of coal mined.

Guaymas, January 20.

CANADA

MANITOBA

A discovery of rich gold ore has been made just off the trail leading from Big Clearwater lake to the Gold Pan mine by E. E. Kain. Mr. Kain saw some of the Gold Pan ore in Minneapolis some time ago, and he came to the district with two other prospectors. The new find has been the result of his search. A number of samples were sent to Bisbee, Arizona, and have given returns running as high as \$400 per ton, while the average of the batch ran over \$60 per ton.

KOREA

The Seoul Mining Co., operating the Suan Concession in Whang Hai Province, reports a total recovery of \$207,050 for December.

Military Appointments

E. R. LIVALL is in the 27th Engineers at Camp Meade, Maryland.

H. C. DUDLEY is with the 36th Regiment of Engineers at Camp Grant.

W. H. COLEMAN has enlisted in the 23rd Engineers and is at Laurel, Maryland.

WILLIAM A. ARCALL, who is in the 148th Regiment, U. S. Field Artillery, is on his way to France.

JOSEPH HYDE PRATT is now Lieutenant-Colonel of the 105th Engineers, at Camp Sevier, South Carolina.

ANDREW NEWBERRY has been promoted to Captain in the 4th Regiment of Engineers, now at Camp Greene.

P. R. HINES has been commissioned Lieutenant in the 318th Engineers, at Vancouver barracks, Washington.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

THOS. B. STEARNS is at Washington.

F. L. BOSQUI is at the Fairmont hotel.

W. W. MEIN has returned to New York.

HORACE F. LUNT, of Colorado Springs, is in Arizona.

WILLIAM B. FISHER is now residing at Santa Barbara.

C. T. NICOLSON has returned from the Malay States to Milwaukee.

THOMAS NEILSON has returned from the Philippine Islands to Los Angeles.

W. J. WATSON is again manager of the Ladysmith smelter, British Columbia.

THEODORE CHAPIN, of the U. S. Geological Survey, is at Silver Lake, California.

WHITMAN SYMMES has returned from Washington, and is now at Virginia City.

G. L. SHELTON passed through San Francisco on his return from Riverside to Ely.

ROBERT C. STICHT has returned to his post as manager of the Mt. Lyell in Tasmania.

WALTER DOUGLAS passed through San Francisco on his way from New York to Bisbee.

D'ARCY WEATHERBE passed through San Francisco on his return from Russia to London.

ROSS B. HOFFMANN is due in San Francisco from Siberia about the middle of February.

HENRY E. WOOD passed through San Francisco on his way from Denver to La Jolla, California.

EDWIN W. MILLS has changed his headquarters as consulting mining engineer to Yokohama, Japan.

H. H. HASSAN has closed the Great Falls mine, in Maryland, and has opened an office in New York.

GEORGE J. YOUNG has become assistant editor-in-chief to the 'Engineering & Mining Journal' at New York.

H. DEC. RICHARDS is now consulting engineer to the Central Eureka Mining Co. at Sutter Creek, California.

X. B. STARNES has accepted a position in the geological department of the Phelps-Dodge Corporation at Morenci, Arizona.

CHARLES H. WHITE, recently professor at Harvard, was an expert witness in the White Caps v. Morning Glory case at Tonopah.

JAMES E. MCGUIRE, recently manager of the Witwatersand Deep mine at Johannesburg, has returned to Grass Valley, California.

DENNIS M. HINES has resigned as mine foreman to the Cinco Minas company, in Jalisco, Mexico, to join the 27th Engineers at Camp Meade.

CHARLES W. COOK, Professor of Economic Geology in the University of Michigan, passed through San Francisco on his way to Los Angeles.

ELLSWORTH H. SHRIVER, Lieutenant in the Regiment of Engineers, has been transferred from the 23rd to the 27th Regiment, and is at Camp Meade, Maryland.

THOMAS VARLEY, superintendent at the Pacific Northwest Experiment Station of the U. S. Bureau of Mines, is in California, investigating the metallurgy of quicksilver.

FRED S. NORCROSS JR., superintendent of mines for the Canada Copper Corporation, has obtained a commission as Captain in the U. S. R. Engineers and is at Camp Lee.

E. H. CLAUSEN has received a commission as Captain in the Engineer's Section, O. R. C. He is now reconstructing the 20-stamp cyanide mill of the Colorado Mining Co. at Arroyo, Mashate, P. I.

THE METAL MARKET

METAL PRICES

San Francisco, January 29

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.95
Antimony, cents per pound.....	17.50
Antimony (wholesale), cents per pound.....	14.25
Electrolytic copper, cents per pound, in carload lots.....	23.50
Electrolytic copper, cents per pound, in small quantities.....	24.67 1/2
Pig-lead, cents per pound.....	7.00—8.00
Platinum, soft and hard metal, respectively, per ounce.....	108—116
Quicksilver, per flask of 75 lb.....	\$125
Spelter, cents per pound.....	20.00
Zinc-dust, cents per pound.....	20.00

ORE PRICES

San Francisco, January 29

Antimony, 45% metal, per unit.....	\$1.00
Chrome, 34 to 40%, free SiO ₂ , limit 8%, l.o.b. California, per unit, according to grade.....	\$0.60—0.70
Chrome, 40% and over.....	\$0.70—0.85
Magnetite, grade, per ton.....	\$8.00—10.00
There is little demand for either calcined or crude magnetite.	
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.	
Tungsten, 60% WO ₃ , per unit.....	26.00
Tungsten ore remains firm.	
Molybdenite, per unit MoS ₂	\$40.00—45.00

EASTERN METAL MARKET

(By wire from New York)

January 29—Copper is quiet and unchanged at 23.50c. all week. Lead is inactive and firm at 7c. all week. Zinc is dull and steady at 7.87c. all week. Platinum is unchanged at \$108 for soft metal and \$116 for hard.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Samuel Montagu & Co. states that a royal proclamation was issued on January 21 providing for the establishment of a branch of the Royal Mint at or near Bombay. The gold coins issued therefrom are to be current and possess the same legal tender that they would have done had they been coined and issued in England. The proclamation is to become effective next June.

Tin remains a market without quotation. All prices are absolutely nominal and it is almost impossible to quote any price whatsoever. Banca tin for shipment January-February from the Far East has been done at 67 1/2 cents.

Charles Hardy says: Legislation is proposed for Government control of the mining and mineral industry, especially in regard to such ores as are produced in small deposits such as chromite, manganese, tungsten, molybdenite, graphite and others. The outcome of this bill is expected by some trade, and meanwhile the buyers of some of the minerals are hesitating and buying only for their immediate wants.

The tungsten market has been quite steady during the past week. Considerable business has been done in spot lots and most of the off grade ore which has been on the New York market for some time is expected by some trade, and meanwhile the buyers of some of the minerals are hesitating and buying only for their immediate wants.

The Canadian government has lifted the embargo on molybdenite and recently offers for molybdenite as well as ferro-molybdenum have been received in this country. The reason for the lifting of the embargo is said to be due to the fact that the Canadian producers complain that at the prices fixed by the Government their production was handicapped by selling at the higher prices ruling in the United States, their production would be stimulated to everybody's advantage. Here the arrivals have been larger than for some time past and the market ranges from \$2.15 to \$2.20 per lb. for the 85% concentrate.

The January price for manganese remains at \$1.20 delivered at furnace for high-grade material. Arrivals from Cuba have been small on account of the rainy season in these markets.

Chrome ore is scarce and people are asking as high as \$1.50 per unit for material over 45%. One carload is now offered at that figure, but the sale has not been consummated.

Eastern Metal Market

New York, January 23.

There is no activity in any of the markets, and this has been the striking feature for weeks. Such Government buying as is being done is conducted very quietly in most cases.

Copper prices are not to be changed for four months. The market is quiet.

Tin for spot delivery is still scarce with prices nominal at about \$6c., New York.

Lead is at a dead stop, with prices nominal.

Zinc is still inactive at unchanged prices.

Antimony is in poor demand.

In the steel trade the curtailment, due to the five-day shut-down, is estimated to have been from 10 to 15% from the already restricted rate of recent weeks. The steel trade as a whole felt the order for fuel conservation less than other industries because so large a part of the output is now for the Government or its Allies. In the East snow storms and more cold waves have added to the blockade and have neutralized to some extent the possible good to be accomplished by the five-day idleness in general. It is the severest winter in the Eastern States in many years.

COPPER

The copper industry has been generally exempt from the industrial paralysis in the East due to the Fuel Administrator's five-day shut-down. The industry pertains mostly to the West, or is exempt because of necessary continuous operation. In the New York district two large refineries were affected differently, due to varying interpretations of the local fuel administrators. The large refinery of the Nichols Copper Co. on Long Island closed, but that of the American Smelting & Refining Co. in New Jersey operated, having been exempted by the local administrator. The shut-down of the Long Island refinery, however, was for one day only, exemption having been later granted. The usual rumors are prevalent as to the necessity for a higher price for copper, probably 25c., but there is not much ground for belief that any change will be made. Sales are being made of large and small lots at the Government prices of 23.50c. and 24.67½c. per lb., as regulated by the Copper Producers' Committee. There has been some disinclination to buy ahead in the hope that the price will be reduced. There is a rumor that some copper has been sold in Canada by Americans at higher levels than the fixed prices, but this is not confirmed. It has been ruled by the Copper Producers' Committee that out of town dealers may add 5% and the cost of the freight to the Government price of 23.50c. when selling less than carload lots. Newspaper advice from Washington states that on the recommendation of the War Industries Board President Wilson extended, on January 22, the price of 23.50c. per lb. for copper until June 1.

TIN

There has been no change in the market in the last week. Consumers dropped out when the fuel conservation order was announced, and remained out of the market to see what its effect would be. There was no effect noticeable. Buyers are extremely cautious. Dealers are having much trouble solving problems connected with the rules laid down by Government regulation, and there is much confusion and delay. Permits for shipments from England are still held up for the principal grades. Some off-grade metal is allowed to come, for which there is a good demand from small consumers. These are specially hard hit, and it is the belief of some that there will be no relief until July. Offers of metal for shipment from the East have not been plentiful in the last week. The arrivals to January 22, inclusive, have been 965 tons, with 5300 tons

reported afloat. The London tin market is higher again. The quotation yesterday, January 22, for spot straits was £302 per ton, against £299 10s. a week ago.

LEAD

The transportation problem with its many difficulties has completely tied up the lead market which has come to a decided stop. It is nominal at 7c., New York, or 6.85c., St. Louis, in the outside market, with 6.75c. the New York quotation of the leading interest. The situation at this end is tight, with the market firm. Metal is not being received in plenty, and stocks are diminishing. Some predict an 8c. price before many weeks. Offerings are not large, some producers stating that they do not have the metal to sell, while others say that it is useless to offer it, for it cannot be shipped. Many consumers are in a similar frame of mind. They refrain from purchasing because they not only have large quantities on the way but also because they feel there is little chance of getting it if they buy it.

ZINC

The principal topic in the zinc trade, outside of the general stoppage of industry for fuel conservation, has been the meeting last week in Washington between the Zinc Committee and the War Industries Board. It was held primarily to discuss a fixed price for grade A zinc, but no decision has been announced yet. It is not believed that price Western and other grades will be regulated, but that they will be left to their regular course unless a runaway market should develop. If a price on grade A is fixed, it is generally expected here that it will be at 12.50 to 13.50c. per lb. The Garfield order to shut down industry, together with the 'coalless Monday,' has rather upset nominal conditions here in the last four or five days, but the market is nearing its normal state again. Inquiry is reported as fairly good, especially for prime Western, but one representative of a large producer states that this grade is rather scarce, more so than would be expected in view of the large stocks of zinc in general reported as of the year end. Sales are being made at 7½ to 7¾c., St. Louis, for January-February delivery, but there is not much doing beyond March. A continual contraction in production is reported. Many producers can operate only at a bare profit at present levels. Quotations today are 7½ to 8c., New York, for prime Western for early delivery with slight premiums asked for future positions.

ANTIMONY

Chinese and Japanese grades are unchanged at 14 to 14.25c., New York, duty paid, for spot and early delivery, but the market is firmer, due to reported fairly large purchases by the Government again this week, details of which are withheld.

ALUMINUM

The market for No. 1 virgin metal, 98 to 99% pure, is unchanged at 36 to 38c. per pound, New York, for spot and early delivery. No agreement is said to have been reached yet as to a fixed price for the metal.

ORES

Tungsten: There are Japanese agents in New York offering tungsten ore mined in Japan. Prices are unchanged at \$24 to \$26 per unit in 60% concentrates, and the market is steady with a fair business reported, especially in spot lots. Ferro-tungsten has been offered at \$2.35 per lb. of contained tungsten, which is probably about the market.

Molybdenum and Antimony: Quotations range at \$2.15 to \$2.20 per lb. of MoS₃ in regular concentrates, with offerings more liberal because of the lifting of the Canadian embargo on shipments to this country. There is nothing to report in the antimony ore market in this district.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

HEAT-TREATED GEARING

By W. H. PHILLIPS

Steel gears may be divided as to material and structure into two general classes, namely, alloy-steels and carbon-steels. Alloys of nickel, chrome-vanadium, and similar elements with the steel, produce a very strong tough gear which, however, on account of its high cost, is practicable for only a few special uses. The great field of gearing is served by carbon-steel products with entire satisfaction.

Since it is possible by heat treatment to increase the life of carbon-steel gears by as much as 200 to 400%, with an increase in cost of but 25 to 50%, these processes have received much attention. There are now three general classes of treatment: (1) oil treatment, (2) case-hardening, and (3) special treatment.

There are applications where the service is so light that the resultant long life and low maintenance-cost do not justify a high-grade product. There are other services where the gear must transmit a uniformly high torque without sudden jars or dynamic blows, in which case it is a question of wear alone, requiring such hardness of the surface as is found in the case-hardened product. There are other applications where the load to be transmitted is uniformly low but subject to occasional shocks. This last-named condition requires a gear with only medium hardness but with high ductility, such as the first-class or oil-treated gear. There are installations, and these are in the majority, where the service imposes both the heavy duty with its resultant wear as well as shocks with the liability of breakage. It is for such service that the third class or special grades have been developed. By analyzing the conditions and selecting the proper grade, it will be possible to obtain the best results. With the ever increasing knowledge of steel and its possibilities of its heat-treatment, which are being accumulated from year to year, the first two grades were improved gradually until now they have been perfected as far as possible and the metallurgist for some time has been looking to other fields for a grade that would include the good qualities of both while yet supplying what they lacked and, if possible, reducing the cost of the heat-treatment. At stated before, the alloy-steel had to be eliminated on account of its cost, and the only course left was to develop a treatment for carbon-steel that would afford the required results. Several of these so-called special grades were introduced, one of the more notable being the 'BP' grade manufactured by the R. D. Nuttall Co. of Pittsburgh.

It was found that, by slight changes in chemical structure, a combination could be obtained, which, when subjected to a special treatment, produces physical properties peculiarly adapted to gearing. The hardness at the surface of the steel is from three to four times that of untreated steel, and grades off slightly toward the centre of the tooth until it is from two and one-half to three times as hard as untreated steel. This reduction in hardness is in a straight-line ratio, and each fibre of the steel, from the surface to the centre, or the neutral axis of the tooth, which may be slightly to one side of the geometric centre, will be stressed in proportion to its ability

to carry the load. So that, when the tooth receives a blow or a shock every fibre is carrying its share of the load. The ductility of this steel is comparatively high, and is in inverse ratio to the strength. The metal is homogeneous, there being no line of demarkation between any two fibres. While the surface of the tooth is hard, it is at the same time tough and will not check nor spall. It is often advisable to treat only the pinion of a combination, it being the weaker and hardest-worked member. A pinion so treated, due to the character of the hardness developed, is not liable to cause excessive wear on the meshing untreated gear. It can

SECTION OF BP GEAR, SHOWING
FINE GRAIN AND UNIFORM
STRUCTURE

SECTION OF ORDINARY UN-
TREATED GEAR

be readily seen that a gear of this type, which is of moderate price, will have a pronounced tendency to overcome breakage, and at the same time will give a high resistance to wear. It should at least triple the life of untreated gearing, and eliminate the cost of damage and delays caused by gear breakage.

If by increasing the cost of gearing from 25 to 50%, a gear is produced that will more than triple the life of the untreated steel-gear and at the same time eliminate breakage with its consequent damage, there can be no doubt as to its economy. A few of the advantages to be derived by such a step are: (1) lower ultimate cost of the gearing, (2) reduction of time-loss, (3) reduction of labor-cost in maintenance, (4) reliability. For example, the untreated gear costs \$20 and runs one year. The treated gear costs \$30 and runs three years. This would show a saving of \$30 on the initial cost. If it requires two hours to make a replacement, it would require six hours to replace the \$20 gear three times, and but two hours to replace the \$30 gear; this gives four hours saved in labor, and four hours saved in the output from the machine. The hazard of breakage, with its consequences, is an unknown factor, but may be serious in some services. The wide application of the heat-treated gear not only in railway and automobile operation, but also in many other branches of industry, such as steel mills, foundries, glass plants, and mines, has been so successful that it is not a question of heat-treated v. untreated gearing, but rather the selection of the proper grade of treated gearing for the service to be performed. In conclusion it might be said, with many industries of the country over capacity, the necessity for reliability of the machine parts was never before so necessary nor the consequences of a break-down so costly. A careful study of gear in industrial plants and mines should be made at this time, and changes that will insure increased reliability should be acted upon at once.

CRUSHING ROLLS

Engineers and Mill Operators have long recognized the fact that if corrugating and flanging of roll shells could be eliminated, there could be no more satisfactory and economical way of preparing ore for subsequent treatment than by crushing in rolls.

IN TRAYLOR HEAVY-DUTY CRUSHING ROLLS WITH THE "FLEETING ROLL" OR AUTOMATIC LATERAL ADJUSTMENT THE HERETOFORE IMPOSSIBLE HAS BEEN ATTAINED.

THE TRAYLOR NON-CORRUGATING ROLLS

will neither flange nor corrugate when fed according to the most approved methods.

This automatic lateral adjustment is so simple too—just six parts of very heavy construction incased in a dust-proof, oil-tight case, and receiving its motive force from the fixed roll shaft—so adjusted that it requires one hour for the fixed roll to make two complete cycles of the lateral movement.

A Greater Tonnage of Finished Product per Horse Power Consumed—A Greater Tonnage Crushed per Set of Roll Shells—A Smaller Percentage of Oversize—A Smaller Percentage of Absolute Slimes Are All Made Possible by the "Fleeting Roll."

Bulletin PR-1 tells the whole story.

Send for it.

EDITORIAL

OUR New York market letter calls attention to the fact that shortage of coal for the railroads in Brazil has led that Government to announce a total suspension of shipments of manganese ore for a period of 60 days.

FOR the information of the public the War Trade Board has issued a bulletin giving the rules and regulations adopted for the control of foreign commerce. It includes the President's proclamations prohibiting the exportation of certain articles, the Trading with the Enemy Act in full, legal forms for making application for export licenses, and a mass of detail that should be known by all persons engaged in foreign business. A copy of the bulletin may be obtained from the Division of Information of the War Trade Board at Washington.

INTERNATIONAL rates of exchange are becoming interesting even to the man in the street or the nearest equivalent in complacent ignorance. We draw attention to the fact that current exchange-bureau rates at Hongkong are \$5 in American paper for \$4 American gold coin, a premium of 25% for the metal over its equivalent in a monetary medium equally current at par in the United States or over corresponding bank exchange. Is this the small cloud on the horizon? Does it signify a reactionary appreciation of gold after the orgy of paper-credits on which the nations are now spending their financial vigor?

COLONEL W. B. THOMPSON, whom we know not in his military capacity but as a resourceful and honorable operator of mines, is reported to have given a million dollars to the Bolsheviks to aid them in spreading their propaganda among the Austrians and Germans. He is credited with having aided these incendiaries in setting the Tenton coat-tails on fire. Colonel Thompson may know what he is about, but he looks to us like a man hiring some small boys to set fire to his neighbor's hay-field regardless of the danger of the wind blowing sparks on his own crop. This anti-social anarchistic radicalism of the Bolsheviks is not a thing to play with; before the War ends we may find it difficult to prevent spontaneous political combustion of a similar kind in our own demesne. Returning Americans dwell upon the lofty ideals and sterling qualities of the Rus-

sians; we know the Russians also; just now they appear to be going down a steep place into the sea, led by as irresponsible an element as ever sat in places of power. Trotzky and his crew would come to terms with the Enemy tomorrow, condone the violation of Belgium, ignore the devastation of Serbia, and forget the frightfulness that has horrified the world, in order to make Russia safe from further invasion. All this talk of self-determination by a people that refuses to fight is pitiful nonsense. Those that are either too proud or too timid to fight organized hell will have to lick the boots of the Prussian.

SOME of the people have wondered what is the matter with Argentina. One conspicuous fact about Argentina is that she has not cast in her lot with the nations that are fighting Germany. Perhaps President Irigoyen is after the halo that signifies "He kept us out of war." We do not insist upon the validity of the argument, yet an odor of sauerkraut these days is suspicious, and when we observe the list of authors of the bulletins issued by the Argentine 'Dirección General de Minas' and find a succession of names such as Beder, Stappenbeck, Kühn, Stieglitz, Windhausen, and Groeber, we wonder whether the matter is that the Government is too hyphenated. To be perfectly fair we must admit that considerable criticism has been aroused in this country over the large Teutonic flavor of the personnel of some of the departments at Washington, especially where those departments have shown a tendency to inaction or obstruction.

KNOWLEDGE of flotation is beginning to filter through the daily press and the public is being treated to sundry sophomoric efforts at technical description. In one of our local organs of misinformation we read that "the ore is ground up with a little oil," and "when the ore is crushed and the pulp mixed with water and properly stirred up by machinery, air is injected to make the resultant soup, so to speak, get frothy. The froth is skimmed off as it reaches the top, and as it liquifies or is evaporated, the metal is automatically precipitated." This might be worse. "The amount of oil," we are told, "averages about two pounds to the ton of ore," from which we suspect the source of the reporter's information. "Whisky or vinegar, phenol, cresol, pine-oil,

eucalyptus oil—almost anything that will make a froth can be used successfully." This should please a prohibitionist and might refer to a politician.

BAINBRIDGE COLBY, a member of the American War Commission, on his return from Europe, exclaims: "The sumptuousness of life here is terrible. Think of the congestion of automobiles on Fifth avenue, and they have not motors enough at the front in France. We have made no sacrifices. So far we have only been a sentimental factor in the War." Much of this is true. The mobs that fill the hotels at night, dining lavishly and dancing to rag-time music, provoke the contempt of any thoughtful man. Out of our hundred millions, 3 or 4% are doing all they can, in service or in money, but the bulk of the population is still trying to 'forget it,' to do 'business as usual,' to proceed on the even tenor of its way, despite the irritation of taxes and subscriptions, as if the destiny of the world—and of America—were not in the balance.

A SERIOUS controversy between the United States and Spain would be a most regrettable event. We can understand that the Germans would be delighted to cause a rupture in the pleasant relations that have existed between the two countries during recent years, and it must be borne in mind that the Germans are even more active in Spain than in America. The rabid socialists of Catalonia are working hand in glove with the Teutons, and as the bulk of Spanish manufacturing is in that border province it has been possible to hinder in many ways the shipment of supplies to our army in France. The story that King Alfonso inclines toward his remote kindred in Austria, however, would seem to be of Teutonic inspiration. The security of the Spanish monarchy rests at this time upon neutrality, and a constant effort has been made to keep in power a neutral ministry. The struggle in the Cortes between the 'Germanophiles' and the 'Germanophobes' has been so violent, however, that ministries have risen and fallen like ninepins in a bowling-alley, in consequence of which the King has been forced to carry the appeal to the country. We believe that the popular sentiment strongly favors the Allies, and if international complications can be averted for a few weeks until the elections are over, it is likely that the new chamber will be found to represent opinion favorable to the maintenance of a genuine neutrality. Our relations with Spain will exert a powerful influence upon the attitude of the South American countries, so that the case is one that demands the exercise of careful and wise diplomacy.

IT seems reasonable to suggest that the interminable litigation over the flotation patents might be settled by a technical commission, on the precedent created by the Selby Smelter Commission, which ended the wrangle between the Selby Smelting & Lead Company and the recalcitrant farmers of Solano county. In that case a

stipulation was made by the attorneys of the plaintiff and the defendant setting forth that, owing to the expense and delay to be incurred in determining the merits of the suit by the Court, it seemed preferable to place the matter in the hands of a technical commission, which should ascertain the facts and "fix and determine the conditions under which the defendant's plant may operate." Both litigants bound themselves to abide by the findings of the Commission. As originally constituted this Commission consisted of Messrs. Joseph A. Holmes, Director of the U. S. Bureau of Mines, William F. Snow and Ralph A. Gould. Dr. Snow was unable to serve, his place being taken by Mr. E. C. Franklin of Stanford University. Another precedent has been set by the fortunate mediation of the Government between the competitive manufacturers of aeroplanes, resulting in concessions that gave compensative advantages to the litigants, while the imperative needs of the country in its preparation for war were met intelligently. It seems to us that a commission headed by a broad-minded technologist to be nominated from the U. S. Bureau of Mines by the Director of that bureau, Mr. Vau H. Manning, together with a nominee from each of the belligerent camps, would constitute a commission able to settle the controversy and terminate a litigation that is checking the wheels of metallurgical progress.

WHEN Mr. Charles S. Palmer was telling his story of Prussian blue, which will be found on another page of this issue, he omitted the reminder that Prussian blue is a virulent poison. It even originated in Berlin, where so much else has been engendered to envenom millions of innocent men throughout the world. The fact that the discovery of the ferrie ferro-cyanide was the result of accident may well be credited; most of the chemicals of commerce were found by blundering upon them in the time-honored pragmatic fashion so dear to the heart of the late Professor James. Ammonia was first obtained and sent over the caravan routes of Asia Minor, to serve the needs of man, from a particularly filthy temple of Jupiter, where the peculiar qualities of that chemical were supposed to have been discovered in a priestly effort to clean house. The reaction in the blast-furnace, whereby cyanogen is formed and gives rise to the well-known cycle, in the course of which active reduction of iron is accomplished, is reputed to have been realized first through the discovery of a workman that a white incrustation accumulating on the outer brick wall of a furnace in Pennsylvania was useful for cleansing his hands. His spouse being a washerwoman, he took some of the salt home to her, and the remarkable properties of the alkaline cyanide led her to move her tubs near to the source of supply at the iron-furnace. Then the chemists took note of it, and traced out the interesting and important cyanogen-factor in the chemistry of iron smelting. We hasten to add that no mortality occurred among the patrons of this venturesome laundress who was content to know that she had found a strong solvent for grease without considering its perilous nature.

Alaska Juneau

Among the mining disappointments of 1917 none is so regrettable as that of the Alaska Juneau enterprise. It is the more noteworthy because it is associated, by reason of propinquity, and in other ways, with the Alaska Gastineau fiasco and the drowning of the Treadwell group of mines. Three years ago the district around Juneau, on the mainland and on Douglas island, was made conspicuous by the publication of estimates and expectations of large-scale low-grade gold mining that appeared destined to make a new and extremely interesting chapter in the history of American enterprise. That chapter is half-written and it is in the red ink of debit. The account, however, is not closed and the final balance may yet retrieve the first failure. The Treadwell group is in a bad way, for even if the deeper ground should be reached and mined by means of a level from the Ready Bullion shaft, the prospect of a return to prosperity is dim. The Alaska Gold Mines, controlling the Alaska Gastineau, has been proved the victim of incorrect inferences from sampling so fatal as to render nugatory the success of a new departure in milling. The Juneau is the immediate subject of discussion. For many years before 1915 this mine was treated as one of the Alaska Treadwell group, although separated by the strait called Gastineau channel, because friendly stockholding interests were represented by interlocking managements. Mr. F. W. Bradley was president and consulting engineer of the Treadwell group, and president of the Juneau company, with Mr. Robert A. Kinzie as resident manager for both mines. The Juneau was owned by a private company that included Wernher, Beit & Co., the Exploration Company, Smith & Perkins, and the Mein estate. Up to 1915 this company had paid \$55,000 in dividends. From 1897 to 1900 inclusive an output of 72,321 tons was treated, after careful sorting, in the 30-stamp mill. The yield averaged \$4.10 in free gold, no concentrate being made. During the subsequent nine years, from 1901 to 1909, an output of 181,436 tons was treated in the same mill for an average yield of \$1.45 per ton, also in free gold. The lower return was due to a change of method, careful sorting giving way to the selection of the best blocks of ground, supplemented by rough sorting. Between 1903 and 1905 two adits, 400 and 500 ft. respectively below the open-cuts from which the previous output had come, were driven through the lode. Slices from the sides of these workings were treated in a 5-stamp mill. This sampling indicated 343 feet yielding 90 cents in free gold in the upper adit and 570 feet of an equal gold content in the lower adit, a part of which, 173 feet long, showed \$1.22 per ton in free gold. In August 1910 Mr. Bradley suggested that \$500,000 be spent in driving an adit 5700 feet long and in raising 900 feet to the upper workings, together with the erection of a 100-stamp mill, a power plant, and such other equipment as might be required to test the possibility of exploiting this big low-grade deposit on an

adequate scale. Moreover, he offered to complete 5000 feet of the proposed adit for 50 shares of the company's stock per linear foot, that is, 250,000 shares for the whole 5000 feet of adit. In 1903 the Juneau company's capital had been increased from 500,000 to 750,000 shares, and the 250,000 shares happened to be intact. Upon the completion of the adit he was to equip the mine as planned, to a capacity of 23,000 tons per month, and in return therefor he was to receive 250,000 shares more, the capital of the company being increased that much. Thus he would become owner of half the enterprise, which, together with his other holdings, would give him the control. On December 19, 1910, an agreement embodying these terms was consummated through Mr. H. C. Perkins and accepted by all the stockholders. Thereupon Mr. Bradley allotted one-third of his interest in the contract to Mr. Ogden Mills, controlling shareholder in the Treadwell mines, and another third to the San Francisco Exploration Company, a partnership consisting of Messrs. J. H. Mackenzie, M. L. Regua, and Mr. Bradley. The allotment of these participations, we believe, was prompted by motives of loyalty and friendship, not with the idea of spreading the risk. Later the stock held by Wernher, Beit & Co. was purchased by Mr. W. H. Crocker.

Where cut by the lower adit the lode showed an average assay-value of \$2 per ton; whereupon Mr. Bradley estimated the cost of operation at 80 cents per ton, and stated that he expected a yield of \$1.45 in gold. The accuracy of this forecast was to be determined by the operation of a pilot-mill then nearing completion. Mr. Bradley's expectation was based on his experience at Treadwell, together with such mining and milling as he had supervised at the Juneau mine itself. He expected that, whereas sorting of $4\frac{1}{2}$:1 had yielded an average of \$4.10 during four years, and whereas selection of ground and rough sorting had yielded an average of \$1.45 during nine years, it would be practicable to obtain an average yield of \$2.70 by sorting 3:1 henceforth when mining in winter underground. In 1912 Mr. D. C. Jackling started the Alaska Gold Mines enterprise, to exploit the old Perseverance mine and adjoining ground, the idea being to send the ore to the mill as stoped, without sorting, and thereby obtain a \$1.50 recovery at a cost of 75 cents per ton. This proved illusory, the yield in 1916 averaging 93 cents at a cost of 71 cents per ton. Returning to the Juneau enterprise: Mr. Bradley strongly opposed a public flotation, intending to conduct it as a private company, arguing that if it were good enough for himself and his friends, he would carry it to fruition, and if it were not good enough he would not shift the loss to the public. Mr. Mills and Mr. Mackenzie were in accord with him from the first, but Mr. Regua thought it advisable to make a public issue and thereby, presumably, render his holding, and that of others, more liquid. Later, Mr. Mackenzie, impressed by Mr. Jackling's successful flotation of the Alaska Gastineau and by the propaganda of Hayden, Stone & Co., who an-

nounced the discovery, during development, of such patches of rich ore as would increase the average yield of the Gastineau mine beyond the original estimate, agreed to Mr. Requa's proposal. Under pressure of the wishes of his two immediate associates, Mr. Bradley also consented to a public flotation. It is fair to add that he had taken note of the fact that the Juneau pilot-mill was then receiving a feed of over \$1.50 per ton on run-of-mine and of over \$3 on sorted ore; and he also had been impressed by the statements of new ore discoveries by the Gastineau mine management. Therefore he consented to a public flotation of the Juneau in March 1915. Shortly thereafter the capitalization of the Alaska Juneau Gold Mining Company was increased to \$15,000,000 in shares of \$10 each. At the time of this flotation a report by Messrs. Bradley and Mackenzie was circulated. In the report they stated that there was available 80 to 100 million tons of ore "that should yield a net profit of from 70 cents to \$1 per ton," and that the company should "be able to earn at least \$1,400,000 per annum." A block of 400,000 shares at \$10 per share was offered to the public with this report. The issue was underwritten and sold successfully at par by a syndicate headed by Mr. Bernard M. Baruch. He took pains to emphasize the conservative character of the technical estimates, so that the shares rose to \$15, at which price considerable unloading occurred. A pilot-mill of 50 stamps, to sample the lode on a large scale, went to work in 1914. During 1914, 1915, and 1916 the record of production was as follows:

	Gold assay-value		Yield		Tailing
	Tons	per ton	Gold	Concentrate	
1914	60,026	\$1.43	\$0.91	\$0.25	\$0.27
1915	179,892	1.48	0.693	0.486	0.296
1916	180,113	0.91	0.039	0.612	0.26

A concentrate of lead and another of iron were produced, but the above figures do not include the lead and silver for which the smelter paid. In the report for 1916 Mr. Bradley stated that up to that date, including the early milling in Silver Bow basin, the mine had yielded 742,220 tons having an average assay-value of \$1.93 per ton for gold only, and that the large-scale milling of the future should be done on an ore containing \$1 per ton in gold, silver, lead, and zinc. The cost was estimated not to exceed 50 cents per ton, having in view a capacity of 10,000 to 12,000 tons per day in the new mill. This may be compared with the expectation, expressed in 1913, of \$1.45 in yield and 80 cents in cost. Evidently the expectations on which the Juneau enterprise was started had begun to suffer a discounting, but the margin of profit had survived and the tonnage of ore assured was so great as to indicate a winning by no means unsatisfactory. Meanwhile the question of building a large mill was under advisement. The 50-stamp pilot-mill was treating the ore at a cost of 29 cents per ton, which was excellent. The question arose whether to add to this plant or to build an entirely new mill of different design. Mr. Bradley was inclined to be cautious, the

technical opinion at his disposal being divided as to the kind of crushing and pulverizing machines best adapted to the Juneau ore. Unfortunately, early in 1915 he became ill, and in May he had to go to Honolulu to recuperate. During his absence Mr. Requa issued a circular, dated May 4, 1915, repeating that the mine contained 80 to 100 million tons of ore "on which a profit of from 70 cents to one dollar per ton will be realized." He suggested the probability that 240 to 300 million tons might become available. He referred to the Treadwell mines as having a lode of undiminished value and size down to 2000 feet below sea-level and predicted the continuity of the Juneau orebody to "an indefinite depth." He announced that Mr. George O. Bradley, who had been consulting engineer to the Utah Copper company, was to design and supervise the erection of a mill having a capacity of 8000 tons per day. Ultimately a daily capacity of 20,000 tons was not an unreasonable hope, he concluded. Shortly after this optimistic announcement the directors, in Mr. Bradley's absence, gave full authority to Mr. Mackenzie, as consulting engineer, with instructions to do whatever was necessary to expedite the preliminary mine-work, and to design and erect a mill of 8000 tons capacity. Two years later, on March 31, 1917, the new mill was ready to start. At the end of May, Mr. Mackenzie relinquished his duty as consulting engineer. A series of difficulties developed, the lining of the ball-mills proved defective, the passing of the ore from the gyratory crushers direct to ball-mills of an untried type failed to produce the desired pulverization, the capacity of the plant was only 1200 tons per day in May and 3274 in December, the highest being 3833 tons per day in November, or considerably less than half that expected. The cost of milling during the last four months of 1917 was 40 cents per ton, the total cost 70 cents per ton, and the yield 75% from a feed assaying 82 cents in gold per ton, so that a loss of 8 cents per ton was recorded, the lead and silver value being absorbed by freight and treatment charges on the concentrate. The average gold-assay value of the mill-feed for the year 1917 was 90 cents. The operating loss incurred since the mill started has been \$144,940. At present an indebtedness of \$1,100,000 exists. The mill is acknowledged to be a failure as it now stands; not only has it failed in crushing capacity but the operating cost is higher and the recovery of gold lower than was estimated.

Another lesson taught by bitter experience is that an exaggerated idea of the width of the ore along the main cross-cut was caused by the drag of the fault, which crosses the lode obliquely. In this locality an excessive admixture of gouge and broken country-rock from the fault lowers the grade of the mill-feed below the economic limit. Hence the disappointing returns, made worse by the high cost of milling, itself due to defects in the equipment. Experiments are in progress with a view to an automatic rejection of the bigger lumps of waste; a re-arrangement of the grizzlies between the jaw-breakers and the gyratory crushers is expected to

exclude the coarse waste and so enable the gyratories to deliver a finer feed to the Bonnot ball-mills. The hope still persists that the duty of these can be raised to 80% of the maximum anticipation, giving the mill a capacity of 9000 tons per day. Preparatory work is now proceeding underground with the intention of using the caving method along the strike of the lode, instead of along the fault, where, as already explained, an excessive admixture of waste has diluted the grade of the ore unduly. In these new stopes, 400 feet west of the fault, and just beyond the ground opened up in the last three years, recent sampling shows \$1.90 per ton. Between the fault and the Ebner boundary, where a cross-cut exposes over 100 feet of lode assaying better than \$2 per ton, there is a stretch of ground 2000 feet long, so that on that side and above the adit there is estimated to be 70 million tons of ore. In 1915 the results and estimates of the Gastineau, the boundary of which is 3500 feet east of the fault, were considered the more important, but later evidence suggests that the Juneau has the better prospects in the opposite direction. Allowing for dilution by waste coming from the hanging wall, Mr. Bradley expects to obtain a mill-feed of \$1.25, or a recovery of \$1 per ton. He is still confident of bringing the enterprise to success, and has assumed the whole burden of responsibility with a courage and a resourcefulness that deserve the highest respect.

Mexican Mining Law

Mexico is reported to be considering a greatly needed reform in her mining decrees. Under the mining law of the Republic the annual rental is a fixed amount for each *pertenencia* of 100 metres square. As a means of wedging the Americans loose from much valuable property, without correspondingly reducing the Federal receipts, the so-called tax, or rental, by decree was made cumulative, that is, it was augmented in proportion to the increase in the number of claims held by an individual or by a single corporation. In consequence, thousands of mining claims have been surrendered by Americans, while the burdens have accumulated upon those who still cling to their holdings in that inhospitable country. It must not be assumed that the proposed change in the basis of rental on mining-leaseholds is to be made in deference to American interests or through the diplomatic persuasion of our ambassador. It merely implies that oppressive taxation has squeezed out as many American mine-owners as, by that means, can be made to let their property go, and that meanwhile the cost of holding mines under the tax-decrees has grown too onerous both for the Mexicans themselves and for their German patrons, who have been most active in acquiring mining property all over the Republic during the last two years. We can understand that the German-owned *Compañía de Minerales y Metales*, which is the Mexican subsidiary of the American Metal Company, through its representative, Mr. Henry Bruère, who

is at the same time financial advisor to the Carranza government, would naturally have suggested that the time had come for a change in policy. This company has been busily gathering up the properties relinquished by other aliens in Mexico. Most of these properties have passed through the fingers of Mexicans on their way to the new owners, so that they may feel the fleeting material satisfaction of an Ishmael while the Teuton makes off with the birthright. The 'M. & M.' company has bought mines in every portion of Mexico, from the far south to the Rio Grande; it is the largest industrial organization in the Republic today; it has opened extensive coal mines, has acquired the old Madero smelter at Torreon, as well as the one at Saltillo, and has constructed still another smelter at Monterrey. It owns and controls the largest equipment of rolling-stock now being operated over the Mexican National Railways. The early enterprise and courageous initiative of American investors in Mexico have thus been turned to account by the wily Germans who have not only supplanted us in the ownership of vast metal resources in that country, but have thereby acquired a respect in the eyes of the people that serves to intensify their contempt for the American. These things have been rendered possible, first of all, by the disregard of our Department of State for the rights of our citizens abroad, an attitude that no administration will ever again assume after we have finished our present war for the security of Americans and of democracy; and it has been assisted by the promises and ready cash so freely offered by the representatives of the Hohenzollerns in Mexico City. Mexico is filled with Germans abundantly supplied with money, and it is not difficult for them to persuade the multitude that the Kaiser will win, and that he will then reward his good Mexican friends. We must remember that the facts regarding our preparations for war and the achievements of our Allies do not readily reach the masses in Mexico; the barrier of language and the further obstacle created by the spirit of dominance and disdain assumed by our own citizens in recent years have predisposed the Mexicans to welcome a 'gringo' of another race that is at least in unison with him in hating the American and in scoffing at him. Meanwhile, the mines are passing into the hands of the most exacting alien owner he could have selected, and all that he has to show for them is the pittance extracted by the political favorites for serving as transfer-agent.

It is worth while again to point out to the Mexican people, as we did at length several years ago, that their mining law as it stood then, and as it stands today, is a rich man's law. The Mexicans have been told that they possess a poor-man's bill of rights in the Steffens-Carranza constitution, adopted at Queretaro, but they should note that the new constitution did not extinguish the power of the Government to distribute concessions, which are tools of corruption for the politicians, while they give to monopoly a throttling grip on the economic life of the people. Neither did the constitution open the

mineral wealth of the country equally to rich and poor, and it is the poor who generally discover the new mineral deposits. The cost of 'denouncing' or locating a mining claim represents more money than passes through an ordinary peon's or vaquero's pocket in a year; to hold the claim after getting title he must pay the rental every four months, otherwise it instantly becomes forfeit. No legal means are provided for cheaply retaining possession until he has had opportunity to develop; he must not ship a pound of the ore to meet his payments; he must wait for that until his leasehold title has been issued. To obtain legal possession of a mining claim he first must pay to the Government a sum that would rank a poor Mexican as a capitalist in his mountain pueblo. If the American system of locating and holding mining claims were adopted in Mexico there would suddenly come to light thousands of valuable deposits, now known only to the wanderers in the hills, and kept concealed because they cannot afford to acquire them under the law and develop them, while those who have the money with which to pay the requisite fees will not give the discoverer more than the price of a goat or a bottle of tequila to be shown the vein. In working out the principles of agrarian reform we would suggest to the Mexican public that they include in their programme a sound revision of the mining law, so that the plain man may be able to avail himself of the natural resources of his country to lift himself to independence.

Food Control

Interest in the conservation of food is growing, but not fast enough; neither is it sufficiently general, despite the entreaties of the Food Administration. A large portion of the community remains callous to the urgency of the work being done to regulate our own consumption in order to ensure the supply needed for the less favored of our Allies. We note that Mr. Hoover is seeking further powers from Congress. They are wanted in order to compel the careless and unthinking to share the sacrifice—so small a portion compared with the supreme sacrifice faced by our fighting men. Our own observation leads us to conclude that in many homes flaunting the Food Administration card there is as yet only an incomplete compliance even with the limited restrictions of the wheatless meal per day, the wheatless day and the meatless day each week, and but small regard for the request to decrease the use of butter, sugar, and so forth. 'Hooverizing' is treated a little too much as if it were a novel game, instead of being a deeply serious necessity. It is difficult for unimaginative persons to realize that if they halve their consumption of wheat, and if others like them do so also, the resultant saving among a people of 100 millions will be so enormous as to feed 50 millions in Europe. Apropos of sugar, our people eat about \$250,000,000 worth of candy per annum. The growth of the habit is due in part to the spread of prohibition, the sugar of the candy helping to satisfy the

natural craving for a stimulant; but most of the candy-eating is a mere luxury, often dyspeptic. It seems to us that the manufacturers of candy might be diverted to the making of food-stuffs and chemicals of a more useful kind, considering that sugar is so much in demand. However little the American home may be doing to conserve the food required for export, it is certain that the hotels and clubs are more negligent. Even the least observant can note the waste of bread and of butter. A superfluity of bread is served; and as for butter, the average waiter seems to consider it a sacred duty to add a fresh pat before the preceding is half-gone, even at the close of a meal. The clubs ought to set a good example. They do not. For instance, the serving of fish 'à la Meunière', which entails an excess of melted butter, should be prohibited. Many people seem to be ignorant of the fact that wheat, fat, and sugar are consumed in pies and pastry. The homely doughnut requires lard. Saratoga chips and fried potatoes waste good fat. Eat boiled or baked potatoes. Do not imagine that the eating of macaroni and spaghetti helps the Italians. The fact is that this matter of food conservation is regarded by many grown men as an eccentricity instead of being recognized as a real necessity. It is time to place a taboo on banquets and luxurious eating of every kind, if only to make the unthinking realize that big events are afoot and that millions are starving in consequence of a conflict that will settle the destiny of this and of other countries. As a sign of stupidity we may mention the throwing of rice at the close of a recent wedding at a municipal office. A few pounds of rice do not amount to much, but to throw away good food at a time like this is the act of a fool. So was the burning of tallow candles behind the Red Cross sign during the recent big drive. Indeed, we fear that the only way to make everybody pay due regard to food conservation is to control the manufacture of commodities and to penalize the wastage of them. It may seem undemocratic, but war cannot be conducted on democratic lines, and the sooner we realize the fact the stronger will be our determination to make an end of wars. Of course, if warfare is to become a chronic failing among so-called civilized peoples, it will be absurd to perpetuate our present forms of government, because they are inefficient as military organizations. Democracy cannot survive in a militant world. We intend to make the world safe for democracy, do we not? Then let us, who are staying at home while others are going forward to the front, show a little unselfishness in this matter of food, at least. We are informed that the Food Administration considers the voluntary honor ration per person per week to be

Meat and meat products.....	2 lb. 0 oz.
Butter for table use.....	7 "
Fat for cooking.....	7 "
Wheat flour for cooking.....	7 "
Bread or mixed cereals.....	3 lb. 8 "
Sugar (not including sugar in preserves) ..	12 "

Take this schedule as your guide and ask the housekeeper how nearly you are living in accord with it.

TAILING EXCAVATOR, GENERAL VIEW OF NEW CORNELIA PLANT, AND CEMENTATION VATS

Copper-Leaching at Ajo

By COURTENAY DE KALB

In outline, the leaching of oxidized copper ores with sulphuric acid, and the subsequent deposition of the metal by electrolysis is delightfully simple; in practice, it is full of intricate details and not a few perplexities. When the exploration of the Ajo deposit was begun no one could have foreseen that the success of the enterprise was destined to depend upon the solution of the problem of treating economically 12,000,000 tons of low-grade carbonate ore. An overburden of lean oxidized ground covering sulphides is a common occurrence, and its removal involves an expenditure that must be included in the total cost of mining and treatment of the ore. At Ajo a new condition was presented. Development soon showed that a metallurgical difficulty barred the way to success. The carbonate was not a mere overburden to be thrown to one side for future consideration, as was done, for example, at the Utah Copper, because here the oxidized ore constituted the bulk of the available deposit. Neglecting this, the mine would be of inferior magnitude. Recognition of the fact came early in the course of development. Drilling was commenced in the autumn of 1911, and by July 1912 the company had started Stuart Croasdale upon an investigation to find a metallurgical method suited to the ore. His results are given in a paper published by the American Institute of Mining Engineers (Trans. Vol. XLIX, p. 610). Although his experiments took into account the possibilities of chloridizing, and also of precipitating copper from sulphate solutions electrolytically, the important fact was established that the copper could be leached with dilute sulphuric acid, and precipitated on iron; that the solutions, including their burden of iron sulphates, could be thrown to waste; and yet the process would afford a profitable result when copper was selling at 12c. per pound. In an illuminating review¹ of the known methods of dissolving and precipitating copper, with special reference to the conditions at Ajo, L. D. Ricketts

called this the "brutal method"; nevertheless, it answered definitely an urgent question; it showed that the work of development that had been done up to that time might be continued in full confidence that the simplest and least refined course of treatment would enable the mine to be operated at a profit.

The preliminary tests determined also that fine grinding was not essential. Mr. Croasdale obtained a recovery of 80% of the original copper content by crushing to a maximum size of No. 3 mesh, that is, about 8 mm. This was an exceedingly important point, since fine grinding is expensive. He employed a lixiviant containing 5% sulphuric acid, and this has now been reduced to 3%, so that an original consumption of $3\frac{1}{2}$ to 4 lb. of acid per pound of copper recovered has been lowered to $2\frac{1}{2}$ to 3 lb. Such economy is possible partly by reason of the regeneration of acid in the electrolytic vats. Further work showed that it was desirable to reduce the ore to about $\frac{1}{4}$ in. size.

The earlier studies were made at Douglas, to which point 400 tons of ore were shipped to Ajo. Part of the investigation was conducted by Mr. Croasdale, assisted by H. A. Tobelmann and James A. Potter, while, later, chloridizing and sulphatizing roasts were made by Udey Wedge in the plant of the Pennsylvania Salt Co. at Philadelphia. In order that no confusion may exist it is well to state at this point that the process as finally adopted does not involve any form of roasting. The ore is treated with no further preparation than crushing. Dr. Ricketts has expressed his belief in the great future of chlorine compounds in the hydro-metallurgy of copper, but he considered that sulphuric acid offered fewer difficulties as a solvent for the type of ore to be treated at Ajo. Both Mr. Croasdale and Mr. Wedge tested the possibilities of roasting with salt, but the idea was abandoned on the ground that the advantages to be gained were not commensurate with the extra cost. Mr. Wedge had proposed that both the oxidized and the sul-

¹Trans. A. I. M. E., Vol. LII, p. 747 et 529.

phide ores might be mined at the same time and in the same proportions as they existed in the deposit; in that case the resulting mixture would have contained sufficient sulphur for a sulphating roast, and the experiments proved that this line of treatment would yield a high recovery, but the operation requires careful attention in order to maintain the proper temperatures. Mr. Wedge points out² that CuS , acting as the molecule Cu_2S_2 , decomposes in roasting to $\text{Cu}_2\text{S} + \text{S}$. The liberated S oxidizes to SO_2 above 350°C ., and the Cu_2S , at furnace-temperatures below 500° , reacts as follows:

At higher temperatures, however, the reaction is

The several copper-sulphide minerals behave differently at the same temperatures, but the tendency of all copper sulphides is to form an oxide of some degree at all furnace-temperatures. In order to produce the water-soluble sulphate it is necessary to overcome the tendency to the formation of oxide, and it must be noted that iron sulphide associated with the copper sulphide in the ore is of material aid in accomplishing this purpose in roasting. Mr. Wedge states: "At furnace-temperatures below 600°C . there is formed some basic iron sulphate, which, at temperatures above 530°C ., roasts to Fe_2O_3 and SO_3 , and the SO_3 gas may combine with the CuO to form CuSO_4 , which is practically stable at temperatures below 650°C .; or the CuO may react directly with the $\text{Fe}_2(\text{SO}_4)_3$ according to the reaction

Furthermore, he recalls the catalytic effect of Fe_2O_3 between the temperatures of 500° and 750°C ., causing the further oxidation of SO_2 to SO_3 , which, at that heat, will unite with CuO to form CuSO_4 . When ores containing 1.86% copper, to which 6% of pyrite analyzing 47% S had been added, were roasted in a 5-hearth Wedge mechanical furnace, 95.2% of the copper became soluble in water. Using the solution on successive charges until it contained 15% CuSO_4 , the tailing contained only 0.08% copper. This is a good example of the possibilities of sulphatizing. About the same time, or a little later, Frederick P. Laist made similar tests at Anaconda, where he also demonstrated that a high recovery could be secured by calcining a mixture of sulphide and oxidized copper ore and tailing. Here again the control of temperature was the vital point; if the temperature became too high a large amount of the copper was rendered insoluble either in water or in acid. The problem at Ajo rested more distinctly upon economy in precipitation, for it was easy to leach 80% of the copper from the oxidized ores by merely circulating a weak solution of sulphuric acid through a vat of coarsely crushed ore, and the cost of mining would be greatly reduced by taking the upper carbonate ore first instead of complicating the operation by parallel extraction of the oxidized and sulphide ores.

After having ascertained that the "brutal method," based on the transportation of Alabama pig-iron to Ajo for precipitation, was economically feasible, experiments were undertaken to produce sponge-iron in the Wedge furnace, starting with high-grade pyritic ore from the mines at Bisbee. This ore contains above 45% each of sulphur and iron, and about 2% copper. In carrying out this plan, the gases from the roasting-furnaces would have been utilized for making sulphuric acid. Some of the iron was reduced in these experiments, but the results were only partly satisfactory, and this was confirmed by work of like character by Mr. Laist at Anaconda. Electrolytic deposition of the copper from the leach-liquors promptly disclosed two serious difficulties. One was the production of an excess of acid salts that dissolved copper from the cathode; the other was the fouling of the solution by an accumulation of salts of iron and aluminum. Interesting and technically important experiments were conducted in an effort to overcome this trouble. One set of tests, made by F. L. Antisell, at the Raritan Copper Works, had in view the precipitation of the copper in the presence of large amounts of those salts. He used nearly the same leaching cycle as that finally adopted at Ajo, and he employed SO_2 on a large scale for reducing the ferric sulphate so as to avoid resolution of copper during electrolysis. His method depended on a patented anode consisting in a wooden case packed with coke, and having an elongated rectangular graphite energizer in the centre. The solution passed upward over the cathode and downward through the 'basket' anode, issuing through an opening in the bottom. At first difficulty was experienced in obtaining complete absorption of the SO_2 , but even with this the results were good in some respects. Nearly two pounds of copper was precipitated per kilowatt hour, but the anode proved cumbersome and poorly adapted to large-scale operation. Parallel with this F. A. Pope and A. W. Hahn were engaged to test a method for the removal of the iron and most of the other impurities before sending the solution to the electrolytic vats. It involved a counter-current leach, so controlled as to admit of drawing two grades of solution from the system, one of which was relatively much higher in iron than the other. To the high-iron solution was added a calculated amount of finely ground roasted ore containing copper oxide. This removed from the solution about 90% of the iron and 80% of the alumina. The process offered many advantages, and was eminently successful at the experimental plant at Ajo, where 329 tons was treated in this manner, but it would have necessitated the complication of the large works with fine-crushing machinery, agitators, and filter-presses, and it would have involved the purchase of high-grade sulphide ore or concentrate. Meanwhile, the leaching tests, under the close supervision of Capt. Greenway, had developed an interesting fact. When neutral solution from the leaching system was circulated through fresh ore a large part of the iron was precipitated, probably as a basic sulphate, and this

²"The Sulphatizing-Roasting of Copper Ores," Utley Wedge, Trans. A. I. M. E., Vol. XLIV, p. 818.

proved insoluble even after the solution had been strengthened with sulphuric acid. That basic sulphates are deposited in the course of leaching raw ores is a well-known feature of the Rio Tinto process, and mention of

FIG. 1. SIZING TESTS ON NEW CORNELIA OXIDIZED ORE SHOWING AVERAGE ASSAYS OF HEADING AND TAILING AND AVERAGE EXTRACTIONS ON SIZED MATERIAL

the fact was made in discussing the application of that system at Bisbee.³ The deposition of the basic crust takes place after all sulphide-sulphur has been oxidized, presenting practically the same case as that noted in the effect produced by solutions containing ferrous and ferric sulphates upon the Ajo oxidized ore. In heap-leaching, yellow and brown basic sulphates form abundantly; these are nearly insoluble in sulphuric acid. It is probable that the presence of basic carbonates may facilitate the formation of these insoluble basic sulphates in leaching the Ajo ore. The same tendency to form basic copper sulphate would also be active, but in the great excess of leach-liquor it would be largely taken up, despite its low solubility.

In May 1914 the experimental staff, consisting of H. A. Tobelmann, J. A. Potter, and J. S. Olmsted, was transferred to Ajo, and in February 1915 a 40-ton plant was erected. This was kept in operation until January 10, 1916. The construction of the present large works was begun in March of the same year; it was designed in accord with the flow-sheet established in the experimental plant. Bi-weekly 'leaching-meetings' were held during this period. The entire staff assembled at these confer-

cees, in conjunction with Dr. Ricketts and Capt. Greenway. Invaluable advice in electrical matters was given by Mr. Antisell; Mr. Tobelmann stood sponsor for the chemical work; and Mr. Potter blazed the mechanical trail. Absolutely free speech prevailed at these experience meetings, and a spirit of cordial teamwork was encouraged. One of the staff, viewing in retrospect the conditions under which the early work was done, declared that the pleasurable intellectual excitement of the leaching-conferences even made them forget the boarding-house. As a measure of the hearty spirit of co-operation encouraged by those in authority this confession will be comprehensible to every mining engineer who has helped to unfold the mineral resources of the West. The scheme then developed comprised the following essential points: The ore was to be crushed to $\frac{1}{4}$ in.; the vats were to be of lead-lined concrete with wooden false bottoms bored with $\frac{1}{2}$ -in. holes countersunk from below; the solution was to be circulated at the rate of $1\frac{3}{4}$ to 2 gal. per min. per ton of ore; the ore-column was to be 12 ft.; the advance solution was to be 15% of the total in circulation; and the leach-liquor was to contain 3% H_2SO_4 , 2% total iron, copper not over 3%, and to have a specific gravity somewhat lower than 1.28. The circulation has now

been reduced to 1 gal. per min. per ton of ore; the column is 15 ft., and the other conditions remain practically unchanged. It is an interesting example of

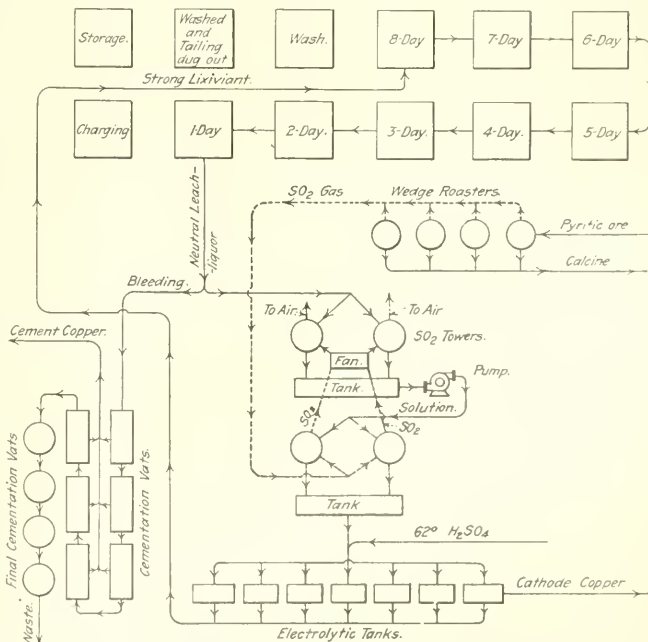

FIG. 2. FLOW-SHEET OF NEW CORNELIA COPPER-LEACHING PLANT

the extreme care exercised by experienced men who engage in mining as a business that, after so elaborate an investigation by so many competent men, the precaution was taken to have the entire process checked in detail by H. W. Morse. The result was a report to the company on January 4, 1916, signed by Morse, Potter, and Tobelmann, recommending the method of procedure outlined above. From the time of starting the 40-ton experimental plant until the final report was made, it had treated 15,000 tons of ore, and had produced 190,000 lb. of cathode copper.

The composition of the ore is given below, one analysis representing the average of various determinations at the laboratory of the New Cornelia Copper Co., with which is compared an analysis of oxide ore made by Utley Wedge, another of the crushed ore in the vat-charges, and, as a matter of interest, a fourth analysis of the sulphide ore, also made by Mr. Wedge.

	ANALYSES OF AJO ORES			
	Oxidized ore			Sulphide ore

The silica in the tailing distinctly increases in relative amount, and it is found that there is a measurable abstraction of iron, alumina, magnesia, and lime. The average quantity of CaO in the solution is about 0.04%, and the MgO tends to increase. Sulphur increases slightly in the tailing mainly through the formation of sulphates from the sulphuric acid used. The shrinkage in weight of the tailing as a result of leaching is 2½%. The effect of the solution upon the crushed ore is, first, to remove the more brilliant blue and green colors, which practically disappear after 24 hours contact, showing a prompt reaction with the carbonates and silicates. The charge now has become dirty greenish gray, and this color persists until about the sixth day of leaching. By that time the greenish tint has faded from the feldspathic phenocrysts, leaving them nearly white. The sharpest change in color is noticed near the end of the leaching period, that is, on the seventh and eighth days; the charge then looks decidedly bleached, but there is no evidence of disintegration. Nevertheless, the structure of the rock-particles has been broken down, and in a

few days they crumble into a mass resembling a clayey sand. When used as ballast or road-metal the tailing consolidates into a moderately coherent cement. The disintegrating effect of the solutions is probably due to elevation of temperature from exothermic reactions as well as from the removal of copper, iron, and alumina, and this may assist in opening passages for the penetration of the lixiviant into the body of the larger particles. It is hardly conceivable that the rock is sufficiently porous to admit of such thorough leaching as was originally obtained on material crushed only to ½-in. size. On the other hand, the fan-shaped fracturing, characteristically present in the larger particles after being crushed in a machine that applies the crushing force radially, may be important in securing good penetration of the solutions. The Symons disc-crushers, which are used for the finer reduction of the ore in the Ajo plant, apply the force in this manner. The relatively slight increase in the percentage of extraction on the smaller sizes as compared with the 3-mesh material is strikingly shown in Fig. 1. The maximum is reached at 10-mesh, where it is 85%, and the extraction curve is nearly horizontal from 8-mesh to minus 20-mesh, decreasing somewhat at the end.

The total volume of solution in circulation is approximately 1,500,000 gal., the rate of flow, or 'advance' as it is locally termed, being approximately 1000 gal. per minute. On entering the leaching-vats it will average 3% sulphuric acid, 2.5% copper, and 2% iron as ferric and ferrous sulphate. It is introduced at the last vat, which holds the charge that is receiving its eighth day of treatment. After upward percolation through this vat it goes through the next vat holding a charge seven days old, and so on to the newest charge, from which it issues practically neutral, and containing 3% copper. It will be observed that no effort is made to precipitate more than one-sixth of the copper content in the solution. In this way the proper strength of the solutions sent to the electrolytic vats is easily maintained. This sixth of the copper content of the solution, however, represents the total copper leached each day; the remainder is merely a fixed quantity always in circulation. It will be noticed also that the leaching is so conducted as to ensure the neutralization of the free acid. The object of this is to facilitate the reduction of ferric to ferrous sulphate in the SO₂ towers, prior to sending the solution to the electrolytic vats, since the absorption of SO₂ by solutions is greatly enhanced when they are neutral. It is important that the solutions on entering the electrolytic department should be practically free from ferric iron. This, as stated previously, is a solvent for freshly precipitated copper, while the ferrous iron functions usefully as a depolarizer. The liquor in circulation is actually quite complex in its composition. From 20 to 30% of its weight consists of sulphates. The complete analysis of a composite sample is given herewith:

Cu	2.635
Fe, total	2.339
Fe, ferrous	1.338

Fe, ferric	1.001
Al ₂ O ₃	2.920
SiO ₂	0.022
CaO	0.053
MgO	1.231
MnO	0.035
Cl	0.012
P ₂ O ₅	0.167
H ₂ SO ₄ , free and as sulphate	20.86
Specific gravity	1.317

The fouling of the solution from the addition of these

AUTOMATIC CHARGING OF LEACHING-VAT; EXCAVATOR WORKING IN ADJACENT VAT

various constituents is kept down, not only by virtue of the deposition of insoluble basic salts in the charges, but by the so-called 'bleeding' or diversion of a certain quantity of the total liquors from the circulatory system to the cementation plant, from which it is discarded after precipitation of the copper on metallic iron. Some operators affirm that better results are obtained in electrolysis from liquor that is moderately 'foul,' and the experience at Ajo shows no disadvantageous effects with a solution of the composition given above, but the solvent power in leaching is decidedly lowered when the salts accumulate so as to raise the specific gravity. At the present time the density is being held between 1.28 and 1.3, and efforts are being made to reduce it as near to 1.25 as possible.

H. A. Tobehmann, the metallurgist of the plant, is assisted in the chemical work by Ben. H. Cody, formerly with the Arizona Copper Co., with a corps of five chemists working in a well-equipped fire-proof laboratory.

During the experimental period, when using the 40-ton plant, the ferric iron was held under excellent control, the consumption of sulphur, introduced as SO₂ for reduction, being 0.78 lb. per pound of copper leached. The reaction upon which the reduction depends is:

The operation is conducted in a group of four towers, each 40 ft. high by 20 ft. diameter, being a specialized type of Glover tower. The gas enters below and rises against the descending solution. At the top the gas from the first pair of towers is conducted through lead pipes to a large lead-lined centrifugal pump. This produces suction upon the first pair, and forces the gas into the second pair. The flow through the second pair of towers, however, is assisted by suction from another similar centrifugal pump, which discharges the impover-

ished gas into a stack. The reduction in the towers is now about 70% efficient, and another tower is being erected. It is desirable that the gas be as strong as possible, since its efficiency is thereby increased. At present the gas contains about 7% SO₂ by volume. It is produced in the same manner as for the manufacture of sulphuric acid by roasting pyrite in Wedge furnaces. There are four furnaces with seven hearths each, 22 ft. 6 in. diam. Each furnace is driven by a 7-hp. motor, and is cooled by 20 gal. of water per minute circulating through the arms, and by air delivered to the column under a pressure of 2½ in. water-gauge. The highest temperature is on the third and fourth hearths, where it is approximately 1200°F. The flue-gases from these fur-

nares are 740 to 760°F.; they pass through a long balloon-flue for cooling, and enter the SO₂ towers at a temperature of about 350°F. After passing through the

VIEW OF WORKS; LEACHING-VATS ON LEFT AND CENTRE

battery of four towers the gas issues with a temperature of 100°F., and 83% of the SO₂ has been absorbed. A Cottrell treater for the removal of the dust and the 0.2% SO₃ contained had been erected, but at present it is not used. The material roasted is the pyritic ore from the Junction mine of the Calumet & Arizona Mining Co. at Bisbee. It averages 45% sulphur and 3% copper. It is desulphurized to 6% S, and the calcine is shipped to Douglas for reverberatory smelting. The pyrite is crushed through a 13 by 20 in. Blake jaw-crusher, fol-

lowed by a 48-in. Symons disc-crusher, reducing it to $\frac{1}{4}$ in. size. A 20-in. belt-conveyor delivers it to gratings set above the drying-hearth of each furnace. The pyrite-crushing plant is driven by a 125-hp. motor. This is entirely independent of the ore-crushing plant. The roasting is done under the superintendence of Herman Snyder. Each furnace roasts 25 tons per day, and three furnaces are in use. The object is to obtain the maximum amount of rich SO_2 gas at the least possible cost, for which reason high elimination of sulphur is not attempted. As a matter of general interest in connection with the quick roasting of pyritic ore the following sizing-test on the calcine is given, the Tyler standard screen-set having been used:

SCREEN-ANALYSIS OF CALCINE AND PYRITE

Mesh	3	4	6	8	10	14	20	-20
Calcine, weight on screen, %.....	9.4	4.1	4.1	7.7	7.0	5.5	6.2	55.0
Sulphur in each size, %.....	14.0	12.3	9.7	7.9	4.9	3.7	2.8	2.4
Raw pyrite, weight on screen, %.....	4.4	7.8	8.5	8.0	7.9	5.8	7.5	49.9

The operation of leaching is conducted on a scale that has no counterpart in America. The vats are exposed to the open air, and are built in two parallel blocks of six vats each. They are of massive reinforced concrete construction, with walls 8 in. thick, strengthened by concrete buttresses. Each vat is 88 ft. square by 18 ft. deep, having a capacity of 116,260 cu. ft. and holding a charge averaging 5000 tons of crushed ore. The material as delivered weighs 93 lb. per cu. ft., the specific gravity of the solid ore being 2.6. The interstitial volume is found to hold 32 gal. of solution per ton of ore. The bottom of the vat slopes gently toward the solution-laundry, which is like an elongated well extending the full width, and is 4 by 5 ft. in vertical section. The entire vat is lined with lead weighing 6 lb. per sq. ft., the sides being protected against wear from abrasion by a lining of 2-in. boards. An interesting incident of the operation of the plant is the boring of a hole through the lead lining by a wood-borer. It was a resistant animal, for it had lived in an acid medium while boring first through the wood and then continuing through the lead. This was proved by examination of the channel cut, and by the finding of the characteristic wood-borer's saw-dust at the point of contact. The hole in the lead showed circular tool-marks as if cut with a fine graver's tool.

The bottom of the vat is protected by a wooden false bottom, made of 2-in. Oregon-pine planks laid close together, and supported on 4 by 12 in. beams spaced 16 in. apart. The boards are perforated with $\frac{3}{8}$ -in. holes, counter-sunk from below. The solution, forced by lead-lined centrifugal pumps, rises from the well or solution-laundry, under the false bottom and issues through the perforations, ascending through a 15-ft. column of ore, and discharging at the ends of the vat over weirs into launders placed between successive vats; thence it passes to another set of lead-lined Worthington solution-pumps, having a capacity of 3500 gal. per minute, which deliver it to the next vat, and so on through the series. These

pumps are of the vertical type, having a cast-iron shell, lead-lined, with a cast-iron boot also lead-lined; the shaft has outside bearings, and is encased in lead, while the impellers are made of an alloy of 90 parts of lead with 10 of antimony.

The charging is done with a special machine designed and built by the Robins Conveying Belt Co. It is a type of traveling tripper with conveyor-belt taking its feed from a main conveyor-belt coming from the crushing plant. The spreading-machine travels the full width of the vat, then shifts the width of the belt and reverses the motion, and thus continues until the vat is filled. No hand-spreading is practised. It requires from 12 to 15 hours to charge a vat, with all four units of the Symons disc-

crushers in operation. The work of filling is done so well that no serious channeling takes place, except around the sides where the narrow space between the lead lining and the inner protective lining of wood allows too free a circulation. This is being remedied by filling that space near the bottom with asphalt and sand. Some stratification is noticed on digging out the charge, where horizontal layers of dark partly leached material are sometimes found. Discharging likewise is done by machinery. The device used is the Hulitt excavator made by the Wellman-Seaver-Morgan Co. of Cleveland. It is an electrically driven, 14-ton clam-shell digger, operated by one engineer and an oiler. Its total length of travel on the rail is 106 ft., and it is able to rotate through 180° in order to reach the corners of the vat. Twelve hours is required to empty a vat, the tailing being discharged from the clam-shell into cars of 20 cu. yd. capacity, on a track paralleling the series of vats. These are standard gauge cars, and the trains are drawn two miles to the dumping-ground situated in a low area in the desert.

The only additional operation connected with the leaching is that of washing the charges. Each charge receives four washes. The first wash was the second wash of the preceding charge; the second was the third wash of the preceding charge; the third was the fourth wash; and the fourth is fresh water. Every first-wash liquor is returned to the regular circulatory system of the plant, after having been strengthened with sulphuric acid. It contains about 2% copper, as against $2\frac{1}{2}\%$ for the liquor issuing from the electrolytic plant. The fresh water for the system of leaching is added through the washing of the charges. It comes from a pumping plant eight miles north-east of Ajo, where it is pumped from a well 650 ft. deep. The water on coming to the surface from the desert valley-fill has a temperature of 104°F. , and is slightly alkaline, but it contains practically no lime or magnesia. The losses of water from the circulatory system per ton of ore are: By evaporation, 5 gal.; by

tailing, containing 11% moisture, 30 gal.; and by 'bleeding', that is, the discard to keep down the saturation from various salts, 90 gal. per minute, or 25 gal. per ton of ore. This makes a total of 304,600 gal. of water to be added daily.

The electrolytic department is a model of neatness and efficiency in construction and operation. It was designed by A. G. McGregor, assisted by J. A. Potter, who is now in charge of the plant, and by Harry S. Montgomery, the 'tank-house' superintendent. There are 152 vats, of which 25 produce starting-sheets, and 127 yield cathodes. They are made of wood, 48 by 54 in. by 30 ft., lined with lead that weighs 6 lb. per sq. ft. Each cell contains 84 lead anodes and 77 cathodes, 40 by 42 in. The lead anodes are alloyed with 3% of antimony. The starting-blanks are made of lead weighing 225 to 240 lb. The electric current is taken from a D. C. generator driven by an A. C. motor, with 85% efficiency in converting. Two separate and identical circuits are employed in the tank-house, each circuit carrying 15,000 amperes and 90 to 185 volts. The current-density in the vats is 8 amp. per sq. ft., with 2 volts between the anode and cathode. At the current-density maintained, the ferric iron being held below 0.5%, with fouling of the solutions controlled as at present, and realizing an ampere efficiency of 75%, it has proved easy to average nearly one pound of copper deposited per kw.-hour. During the first 199 days of operation, that is, up to December 1, 1917, the total amount of cathode copper shipped was 12,894,000 lb.

With every pound of copper precipitated, 1.76 lb. of ferric iron is formed. The solution does not always build up the sulphuric acid to the extent that was anticipated. The theoretic increase should be 1.55 of acid per unit of copper, but in the operation at Ajo typical ratios of copper deposited to acid regenerated are as 1:0.7; 1:1.25; and 1:1. The acid is consumed in oxidizing ferrous to ferric sulphate:

This makes a heavier demand for fresh acid, all of which is brought in tank-cars from Douglas, where it is made at the recently constructed acid-plant of the Calumet & Arizona Mining Co. One of the problems awaiting solution in connection with a reduction of cost in leaching copper ore is the economical recovery of the acid from the sulphates that are necessarily thrown away in the discarded solution.

As previously mentioned, the Ajo ore contains almost no chlorides, but the water-supply carries 0.015% chlorine. After operating for some time it was found that, instead of increasing, the chlorine content was lowered, while at the same time the cathode-copper showed a small amount of that element. This was a pleasant surprise. The lead anodes remain wholly unaffected, whereas it

was expected that they would gradually suffer. In the experiments conducted at the Andes Copper Co., in Chile, with 0.1% chlorine in solution, the lead anodes dissolved and went to pieces.

The electrolytic tank-house measures 168 by 275 ft.; it is merely covered by a roof, the mildness of the climate necessitating no closer housing. The floor is built to a level only a foot below the tops of the vats, and consists of panels of wooden grating. Thus there is no slop in which the men must work. The vats are supported on insulated cement columns rising from a lower cement floor, so that inspection for grounding of the circuit is easy, and leakage and wastage from above can be cared for. The solutions are handled through the plant by Antisell lead-lined centrifugal pumps. The cathodes and anodes are lifted and transported by two 5-ton Shaw

SULPHUR DIOXIDE TOWERS FOR REDUCING FERRIC SULPHATE

overhead traveling cranes. A detail that has added to the economy of operation is a wooden false bottom in the electrolytic vats; this is held in place by lead-clamps burned to the lead lining; it affords a simple and effectual means of saving the bottoms from damage when cathodes happen to fall.

Precipitation of the copper from the discard solution presents nothing new. The ferric iron is not reduced previously, the liquor being sent direct to a series of six concrete vats, and seven wooden launders. The vats have wooden false bottoms, and are filled with embrasp iron scrap from the smelter at Douglas. The scrap is lifted for cleaning by a locomotive crane. From the concrete vats the solutions flow through seven large wooden launders, filled with scrap-iron, and thence to ponds.

No mention has been made of the crushing plant, which is notable chiefly for its simple and massive construction. The coarse-crushing section of the Ajo works was designed and built by A. G. McGregor, and the fine-crushing department by David Cole. The ore is delivered from the mine in trains of 20-cu. yd. side-dump cars. Much of it comes in blocks so large that they look as if destined for revetting a breakwater. The cars discharge

their cargo into the hopper of a No. 24 Allis-Chalmers gyratory crusher, capable of reducing 5 by 8 ft. blocks of ore to 6-in. size. From the large crusher the stream of ore splits into four parts, each going to a separate No. 8 gyratory, these forming a quadrangle about the base of the giant machine above. They reduce the ore to 3 in., and it is then carried by two 36-in. Robins belt-conveyors, up an 18° incline 480 ft. to a 10,000-ton steel storage-bin, provided with cross-belts for distributing it. Beneath the bin are four pan-feeders for delivering the ore to as many 20-in. conveyor-belts that carry it to four 48-in. Symons horizontal disc-crushers, made by Chalmers & Williams. Here the ore is reduced from 3 in. to $\frac{5}{8}$ in. Each Symons crusher discharges to a pair of elevators; these deliver the ore to stationary round-punched manganese-steel screens, the oversize returning to the first disc-crushers, and the undersize going to a battery of eight disc-crushers, which give the ore its final reduction to $\frac{1}{4}$ in. size. The main-line belt-conveyor, also 28 in., takes it from this point up a 16° grade to the sampling-tower. This is a Link-Belt system, carrying narrow buckets on chains so as to cut the falling stream of ore at right angles. Thence the ore is taken by a continuation of the main-line belt to the tripper, which discharges it upon the mechanical ore-spreader in the leach-plant.

The power-plant is a splendid achievement of the highest class of modern engineering, and necessitates treatment in a separate article. It is peculiarly interesting as an example of that marvelous efficiency of steam generation which makes it a competitor with the perfected types of explosion engine, even at a point so remote from the source of fuel-oil. It was designed and built under contract by C. C. Moore & Co. of San Francisco, the same firm that built the magnificent power-plant at the Inspiration mine, and that is now constructing the powerstation for the United Verde Extension. In outline it consists of oil-fired Stirling boilers generating steam at 240 lb. working-pressure with 100° of super-heat at the throttle of the two big turbines. The turbo-generators, each develop 7500 kw. capacity at 80% power-factor. The fuel consumption is 600 bbl. of crude oil per day.

Under the efficient management of Michael Curley, whose early experience in conducting mining operations on a large scale was gained in the iron districts of Michigan, the New Cornelia company is mining 5000 tons of 1.65% copper-carbonate ore per diem, and extracting 80% of the copper.

PLATINIZED ASBESTOS, which is used as a catalyst in the contact method of making sulphuric acid, is made by soaking asbestos in a solution of platonic chloride, drying, and heating to a red heat, when the chlorine is driven off, leaving the asbestos covered with exceedingly finely divided platinum. In the presence of this catalyst at temperatures ranging from 400 to 430° C., 98 to 99% of the SO₂ and O of the air unite to form sulphuric anhydride.

Magnesite as a War Mineral

Until 1915 the United States produced only about 10,000 tons of magnesite annually, although it used 300,000 tons. The domestic supply came from California, and the imported material from Austria, Hungary, and Greece. In 1916 the production in California jumped to 150,000 tons, but the imports, if the calcined material is computed as crude rock, fell to 93,000 tons. Manufacturers of open-hearth steel had difficulty in getting enough magnesite brick to line their furnaces, and companies that made magnesite flooring were short of raw material.

In view of these conditions, domestic production was greatly stimulated. According to estimates by C. G. Yale, of the U. S. Geological Survey, the production of magnesite in California in 1917 exceeded that of all former years, being estimated at 215,000 tons. This quantity and the magnesite produced in the recently discovered field in Stevens county, Washington, estimated by R. W. Stone, of the U. S. Geological Survey, at close to 100,000 tons, makes an output of about 315,000 tons in 1917, or 15,000 tons more than the normal domestic demand. It is believed that the domestic industry hereafter will be able not only to supply the home demand but to produce a surplus for the Allies.

Californian magnesite is mined by open-cuts or underground from veins. The larger deposits are connected with the railroads by spur-tracks or automobile roads. The huge deposits of magnesite discovered in Stevens county, Washington, are only a few miles from a railroad, with a down-grade haul for the load, and are so situated that they can be easily quarried. The Washington magnesite occurs in beds like limestone, in thick lenses up to a quarter of a mile long, exposed on hillsides or ridge tops where large quarries can be opened. Production in this field began with an output of 715 tons of crude magnesite in December 1916. By the spring of 1917 four firms were in the field, and in August the daily shipments averaged 500 tons. The output of Washington crude magnesite in 1917 was between 95,000 and 100,000 tons. Nearly 65,000 tons of this quantity was shipped crude; the remainder was burned by three producers in kilns. Only one company continued production throughout the year; one stopped in August after making a small output, and another began operations in that month.

Magnesite is used not only for making refractory brick and composition flooring, which are its principal uses, but in fire-resistant paint, in the sulphite process of wood-pulp paper manufacture, as a heat insulator or covering for steam-pipes and boilers, in magnesia cement, and for other purposes. Magnesia cement is used for making the decks of ships, the floors of hospitals, and the floors of railroad cars, as well as for floors of larger areas. It has been employed successfully in the European war for making gun emplacements, its advantage being that it sets quickly and has resilience.

Flotation of Chalcopyrite-Pyrrhotite Ore

By WILL H. COGHILL

INTRODUCTION. In 1916 the Bureau of Mines entered into co-operative agreement with the Oregon Bureau of Mines and Geology for the purpose of investigating problems bearing on the treatment of low-grade and complex ores. The writer, as consulting metallurgist, was placed in charge of these investigations, and laboratory room for the necessary tests and experiments was provided at the Oregon Agricultural College, at Corvallis. One of the first problems investigated was the possibility of separating chalcopyrite from pyrrhotite and pyrite by flotation.

Chalcopyrite is the copper-bearing mineral at many places in southern Oregon; in many localities it is intimately associated with pyrrhotite and pyrite. In places these two gangue-minerals form as much as 75% of the ore, so that it is nearly all sulphide.

Gravitation methods of concentrating the copper-bearing mineral cannot be applied because the gangue-sulphides have practically the same density as the chalcopyrite. Magnetic separation does not seem practicable (assuming that the gangue-sulphides can be made to respond naturally or by a preliminary treatment to an electro-magnet) because fine grinding is required to liberate the mineral grains. The methods of concentration now in vogue are hand-sorting and jigging, which eliminate some of the silicious gangue. An inspection of smelter returns gives the impression that the average grade of ore shipped is 10% copper.

Tests. The work of separating the chalcopyrite from the gangue by flotation has been carried through the preliminary laboratory stage with flattering results. As a mill is never considered complete and finished until the orebody is exhausted and the mill has served its purpose, so in this and other ore-testing experiments there are still undetermined factors. However, in order that those who are interested in the separation of sulphides by flotation may have the results of the laboratory work before them, this preliminary report is published by the Bureau of Mines.

The data in Table I show the results of what might be called progressive tests, or those in which the results were similar to those of successful practice. Many random tests were made to determine the nature of the disturbing influences and how to meet them, but only a few of these are mentioned.

TABLE 1. PROGRESS TESTS

Samples used weighing 1 to 16 lb. and carrying 1.13 to 3.2% copper; ratio of concentration from 8 : 1 to 12 : 1.

No.	Name of mine	Through	Grade of tailing	
		200-mesh	Copper	Percentage of total copper
1	Waldo	54.0	0.45	7.2
2	"	74.6	0.70	20.7
3	"	94.0	0.30	6.1
4	"	92.0	0.50	13.0
5	Morrison	44.0	0.12	6.3
6	"	97.7	0.12	5.0
7	Rowley	82.0	0.25	8.6
8	"	82.2	0.20	6.2
9	Queen of Bronze	64.5	0.55	...
10	" " "	?	0.30	23.4
11	" " "	?	0.26	16.7
12	" " "	?	0.23	8.1
13	" " "	95.5	0.55	24.5
14	" " "	94.5	0.50	20.3
15	" " "	91.4	0.35	15.1
16	" " "	92.0	0.90	29.2
17	" " "	77.5	0.70	16.6
18	" " "	99.0	0.60	16.1

All the samples were fresh and unoxidized except 16, 17, and 18. These three contained some malachite and azurite; this accounts for the tailings being higher grade than the average.

Several of the tests were made to conform with the tentative flow-sheet (Fig. 1). The results of one that was made in co-operation with D. C. Morris, representing the American Exploration Co. of Grants Pass, are given in Table 2. This sample was crushed excessively fine. It is likely that 75% through 200-mesh would have

TABLE 2. PRODUCTS OF FLOTATION TEST OF QUEEN OF BRONZE ORE IN CALLOW CELLS

Feed assay, 3.0% copper; sample crushed to 99% through 200-mesh; contained oxidized copper.

No.	Products	Weight of	Percent-	Copper in	Gm. copper	Percent-
		product, gm.	age of total weight	product, %	on 100-gm. basis	age of total copper
54	Concentrate	450	6.0	28.3	1.70	58.5
63	Tailing from middling-cell	925	12.3	3.3	0.41	14.1
65	Tailing from cleaner	227	3.0	11.0	0.33	11.3
61	Tailing	5940	78.7	0.6	0.47	16.1
		7542	100.0	...	2.91	100.0

7542 gm. = 16.6 lb.

been satisfactory. Callow cells were used, but the Minerals Separation type of machines seemed to give equally good results.

As the work was done with the intermittent type of machines, there were necessarily middling products—63 and 65 in Table 2—that have to be disposed of by approximation, as shown below.

RESULTS. From Table 2, the milled products would appear, on a 100-gm. basis, to be about as follows: No. 63 and 65 containing $12.3 + 3.0 = 15.3$ gm. of pulp would produce a tailing running 1% copper.

Then $15.3 \times 0.01 = 0.15$ gm. copper lost. (a)

This loss added to No. 61 shows a total of $0.15 + 0.47 = 0.62$ gm. copper lost, or $0.62 \div 2.91 = 21.3\%$ of the total copper is lost. Hence the recovery is 78.7%.

These two middling products contain $0.41 + 0.33 = 0.74$ gm. copper.

By (a) 0.15 gm. is lost.

The recovery from them is $0.74 - 0.15 = 0.59$ gm. (b)

Assume that this 0.59 gm. of copper is in a concentrate running 25% copper. There would be therefore $0.59 \times 4 = 2.36$ gm. of concentrate. (c)

The total concentrate would then amount to 6.0 (No. 54) $+ 2.36$ (c) $= 8.36$ gm. concentrate. (d)

This means a final concentration of 100 into 8.36 or 12 : 1.

8.36 gm. (d) concentrate contains

1.70 (No. 54) $+ 0.59$ (b) $= 2.29$ gm.

$2.29 \div 8.36 = 27.4\%$ copper in the concentrate.

This method of approximation applied to the tests from samples 1 to 15, inclusive (Table 1), would show an extraction of 90% with an equally high-grade concentrate, except where, as shown by grab-samples of the overflow, the test was stopped too soon. The reader should note in Table 2 that only 15.3% of the charge enters the closed circuit for re-treatment. This quantity, though small when compared with average practice, is excessive for these ores; it was great in this case because the test was prolonged in the effort to float the oxidized copper. The freedom with which the fresh chalcopyrite floats is remarkable. At times there is also a striking play of brassy colors on the overflow.

This reference to color introduces a fertile subject for scientific discussion, but it must be treated briefly here. The first impression was that the color was a true indicator of the grade of the froth. Later work showed that it was not. Sometimes the M. S. type of machine gave a richer looking froth than the Callow type, when analysis showed it to be of lower grade. When the pulps are of equal densities, the M. S. machine gives, without fail, a brassier froth than the Callow. This seems natural because the M. S. machine makes less froth where the bubbles have had more opportunity to gather the chalcopyrite. The burden of chalcopyrite is therefore heavier and more evident than in a Callow machine where the greater number of bubbles—some of them doubtless barren—dart to the surface and form a voluminous froth. The heavy burden of non-wetted

mineral carried by the froth stabilizes it by the 'screw-back' effect that the author has discussed in a recent paper.¹

The Callow froth showed a better color on the concave (upward) surface than on the convex, that is, in the depressions. Although it is true that the weight of the mineral grains should be considered as a factor in causing them to slip down the surface to the lowest point and thus increasing the burden there, the reader should note that the resultant of the molecular forces points in that direction. The fact that the resultant points toward the depression can be emphasized by the following analogy; the physical principles will be discussed at another time. Float a mineral grain in a drinking glass that is thoroughly cleansed so that the water turns up to meet the glass. The mineral will seek the lowest part of the meniscus—the centre. Fill the glass to overflowing so that the liquid surface becomes convex, and the mineral again travels to the depression—this time at the circumference. When floatability is due to the surface-tension film, the floating substance invariably seeks the lowest point on the meniscus.

The ores assay about \$2 per ton in gold. The hand-sorting of a Queen of Bronze sample and assaying revealed that about 95% of this gold is in the chalcopyrite. Unfortunately the flotation concentrate contains too small a proportion of gold. It is likely that the gold is embedded in the cleavage-planes of the chalcopyrite and is released on crushing. The gold in the tailing amalgamated freely in bottle-amalgamation tests, proving it to be in the metallic state.

Only one oil was tried. It was selected from a stock of 22 oils on account of its desirable physical properties. The surface-tension effect of these oils had been determined and plotted by E. H. Miller, of the Bureau of Mines, and the one used was found to give a steeper surface-tension curve than any other oil in stock. This was desirable because it was thought that a froth with a slightly variable surface-tension would, with the solids present, be sufficiently stable. Whether other oils would have proved unsatisfactory was not determined, but it is probable that some of them will be found to serve quite well, assisting in some manner other than by reducing surface-tension, but the point is that the oil mentioned is excellent. Its miscibility is an important characteristic.

Only once, and then by accident, was the ore ground in the presence of an insoluble oil. The insoluble oil acted as a collector on all the sulphides present and spoiled the differential separation sought. The overflow carried only 5% copper whereas 30% copper in the first overflow was desirable and expected when the pulp carries 2½%.

As already stated, this oil reduces surface-tension. It seems strange, in view of all that has been written about surface-tension, that there are no published data on absolute value of surface-tension of mill-solutions. In the

¹ 'Flotation,' T. A. Rickard and O. C. Ralston, p. 195 (1917).

course of these experiments several determinations were made by the drop-weight method. One determination gave: Surface-tension of overflow 65.9, of underflow 69.8. This result is in accord with classic tests made to prove adsorption as given in texts on colloid chemistry. The quantity of oil necessary is minute. One-tenth of a pound per ton of ore is ample. It was added to the

the statements of Zachert² and Gahl³ showing that the influence of iron balls is beneficial.

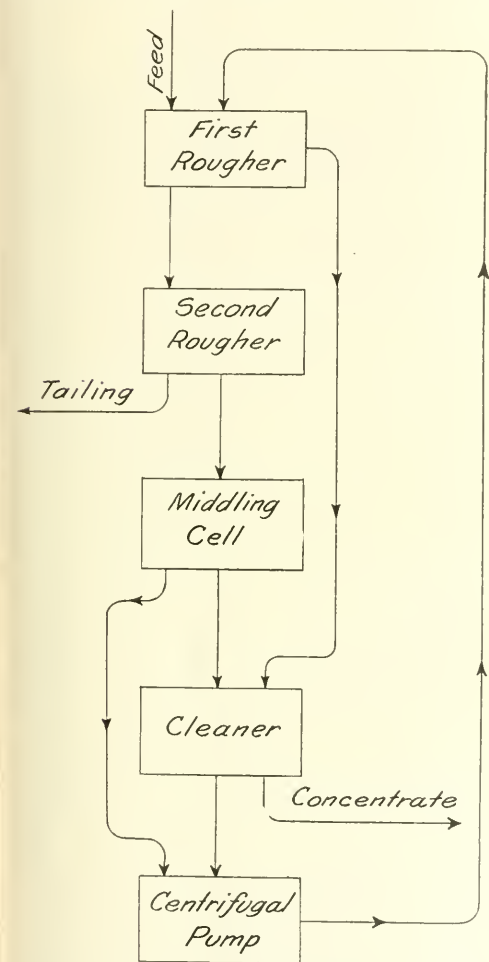

In the work described in this paper no apparatus was available for determining the influence of iron surfaces in a ball-mill, but it was proved conclusively that, for the flow-sheet used, the disc pulverizer is not only objectionable but must be avoided for either wet or dry crushing. The same conclusion applies to a 'made-up' ore containing chalcopyrite. Two comparative runs were made. Each sample consisted of pulp that had been prepared for cyanide tests, and 30 gm. of chalcopyrite. The copper mineral in one was prepared in the disc machine, in the other it was ground to the same degree of fineness in a porcelain mortar. Table 3 shows the relative floatability. The mineral prepared in the mortar overflowed much more freely and gave a higher-grade product.

TABLE 3. RESULTS OF DISC AND MORTAR GRINDING

Prepared in	Overflow Gm.	Copper %	Copper Gm.
Disc	10	14.0	1.4
Mortar	24	16.2	3.9

This experience leads one to declare the disc-pulverizer guilty until proved innocent.

In a method for the electro-deposition of copper, proposed by F. E. Studd, and patented in England (British patent 108,688) pure gaseous SO_2 is directly introduced into cells in which Cu is being deposited from acid solutions containing also Fe, sometimes in considerable quantities. Anode polarization and the formation of ferric salts are thus prevented. Liquid SO_2 may, for this purpose, be led into a reservoir whence the gas passes by pipes and cocks to grids of pipes lying on the bottom of the cells. Steam may be supplied also. The pipes on the bottom of the cells are perforated so that currents of the electrolyte are forced along the surfaces of the anodes, preferably so as to cause circulation in a horizontal direction. A low current density, say 13 amp. per square foot, is employed at the anodes. Temperatures of 49 to 53° C. are preferred. Some of the diluted H_2SO_4 , resulting from the electrolysis, and containing H_2SO_3 , may be used subsequently for lixiviating ore. In order to ensure the reduction of the ferric salts, lixiviation may be prolonged for 10 to 14 hours. The remainder of the acid may be concentrated and heated with sulphur, carbon, or a mixture of such substances, to produce SO_2 , which is passed through condensers to remove the moisture, and is then liquefied. About 24% of the gas may be absorbed previously in a tower by the electrolyte between the lixiviating tanks and the cells. Any iron, aluminum, or other sulphate in the acid employed may be decomposed by S. A part of the SO_2 required may be produced by combustion.

TENTATIVE FLOW-SHEET FOR CHALCOPYRITE-PYRRHOTITE ORE

charge in the cell, and the overflow could be drawn after an interval of a few seconds. Neutral water was used.

The process is simple when two 'don't's' are observed. Don't grind in the presence of an insoluble oil; use it cautiously in any event.

Don't grind samples in a disc pulverizer, and if a ball-mill instead of a pebble-mill is contemplated, make careful tests to see if the iron surfaces have an injurious effect. This is especially interesting in connection with

²Zachert, Victor, 'Beneficial Effect of Grinding with Steel Balls in Flotation,' M. & S. P., May 12, 1917, p. 663.

³Gahl, Rudolf, 'History of the Flotation Process at Inspiration,' Bull. A. I. M. E., No. 117, Sept. 1916, p. 1656.

The Story of Prussian Blue

By CHARLES S. PALMER

What is 'Prussian blue'? It is a common and useful pigment; a dark-blue solid, with an indigo-like appearance, and a bronze lustre. It is used in making wall-paper, calico, ink, and, in modified form, in common 'bluing' for whitening clothes in washing. 'Bluing' is not identical with 'Prussian blue,' but is a closely related derivative. Then there is 'Turnbull's blue,' another closely related chemical, named in the old trade from its supposed discovery by an Englishman, by the name of Turnbull. All of these names are quite old and respectable.

Now, how and why did Prussian blue happen to get its name? Both the question and its answer are interesting; and it is well to remember that there are no real accidents in the survival of such a good trade-name as this. If this beautiful pigment got its name, it did so because it used to be made first in Prussia, and was shipped thence to other parts of the commercial world. And, it should also be noted that, in Germany, this blue is called 'Berlin' blue, as ordinarily used, with some admixtures, to give it added strength and coloring power; while the pure substance is—strangely enough—called 'Paris' blue, probably because the Germans first discovered and used the art of mixing it with foreign adulterations, to produce justifiably industrial results.

The fact seems to be clear that one Diesbach, with one Dippel, discovered Prussian, or Berlin, or Paris blue. Also, it seems to be clear that this happened in the first 10 years of the 18th century—about 1704, let us say. Also, it seems to be universally agreed by the historians of chemical industry, that this same blue pigment was discovered by accident! By accident? Yes, and here comes our story, for there is a well-defined tradition that helps to show how this 'accident' might have happened. And, it is no discredit to this somewhat apochryphal narration that we are indebted to tradition for the preservation of what well may have basis of real fact in its actual happening, for this is just the way that many of our best discoveries are made—by accident—accident in the hands of attentive and interested observers, who take advantage of mistakes to learn something.

Well, the story? This is how I heard it many years ago from the lips of my revered Professor Harris, back at Old Amherst. It seems that on the banks of one of the rivers near Berlin were several shops and factories for the making of soap, dyes, and so forth. One day one of the soap-kettles was neglected, and burnt its contents to a cinder. The workman, who cleaned up the foul mess, was washing out this unfortunate kettle; as he used the river as a natural sewer for his dirty rinsings, someone noticed that where the rinsings from the burnt soap-kettle mixed with the river there was formed, in the water, a new and strange blue discoloration. The water became blue, and down the side of the river, for many

yards, there was the line of the new dark-blue. The thing was strange, and someone determined to find what was the matter. Why should the rinsings from a burnt soap-kettle produce this new blue discoloration in the river-water, which was not different from the ordinary river-water? Not different? Yes, it was different! Above the site of the soap-factory was another factory; and the rinse-water from that factory was found to be peculiarly different from the rest of the river-water farther out where the stream was clearer. Come to think of it, the river was always about that way, somewhat discolored from the customary rinsings from the dye-factory up-stream. But today, with the accident to the soap-kettle rinsings, there was the making of the new blue in the river-water, just where the two kinds of rinsings met. Perhaps the same thing had happened many times before, perhaps just as often as a soap-kettle had been burnt and rinsed out in the obliging river, with its various mixtures of rinsings from all the factories up-stream. Well, the next thing was to ask the people up-stream as to just what kind of old stuff they had been throwing away into the river. Of course they did not know of anything specially queer that they had been doing, except that they had had a lot of some old mordant, green vitriol (sulphate of iron) or something of that sort, which had gone bad; at any rate, the dye-people's answer was enough to set the keen-eyed observer, at the burnt-soap-kettle end, to thinking—and doing.

The story goes on to say that the soap-maker had the wit to try what would happen when one mixed the rinsings from burnt soap-kettles with a solution of green vitriol. The practical chemistry of it all is quite reasonable and clear. Indeed, it would be rather difficult to mix such rinsings, with such antecedents, and not get blue colors with solutions of green vitriol, so, the industrial birth of a new and wonderful pigment came about. But can we vouch for the story? No, for we were not there; but, in some way, someone found out; and the story has all the earmarks of a good historical basis; for it is just the way in which many of the best discoveries and inventions are made, have been made, and will be made, to the end of time. This same Prussian blue is made all over the world, and in many varieties and subtle differences of shade and use. The moral? If there has to be a moral with the story, let another story tell it.

When Sir William Herschell, a German musician who settled in England and became one of the world-famous astronomers, had to make his own telescopes, he made 293 before he got one that suited him, because none of the other 292 was quite good enough. When this same Herschell discovered the planet Uranus, he was simply making a systematic survey of all the stars, and at first he thought that he had found only a comet; and he used to say that he was like old Saul, the first king of biblical Palestine, who "went out to seek for his father's asses, which were lost, and found a kingdom."

PRUSSIAN BLUE is quoted at 67c. per lb., with the demand exceeding the supply.

Potosi

By MARK R. LAMB

It is bad enough—even disgraceful—to have to admit that the tin mines and the copper mines of Bolivia are not American-owned, especially as our representative mining men have had an opportunity to know the important properties. But to allow Potosi, the biggest mineral deposit in the world—bigger than any iron mine, we know—to allow such a deposit to remain with its present owners is nothing short of a crime!

The mountain has been looked over in a half-hearted way by a number of engineers and promoters, but they not only failed to appreciate the mine, but have failed utterly to appreciate the ideal legal conditions surrounding the property, and this in spite of the fact that Don Luis is gradually absorbing the mountain before their very eyes.

In order that the reader may grasp conditions, I shall begin by saying that all geologists and near-geologists are proud to admit that the big wide veins of solid silver worked by the early Spaniards (none of your low-grade 1000 or 2000-oz. ore) were merely the surface ramifications and fissure-fillings at the top of the main deposit. Anyone who has been to Potosi can make you the sketch of the vein-formation of the mountain. It resembles the upper half of a spider's web with the 'parlor' below the present workings and somewhere below the base of the mountain. All the veins (in the imaginary sketch) tend toward a common centre—and *what* a 'parlor' this will be!

The early miners were only after silver; the tin merely bothered them. All the old tailing has been accumulating for years for Mr. Lawrence and his friends, who will have them out with a dredge in a short time.

Those solid silver veins required special laws. It will be readily admitted that to give a claim of any considerable area of ground on such veins to one man would be unfair to the rest, so it was arranged to allow the workings of the veins on a simpler and much fairer basis. It is only necessary to go upon the mountain, and use good judgment in picking out a mine (there are thousands) formerly worked and now abandoned and begin work—just like that! You pay two dollars and can work anywhere your vein leads you so long as you do not break into any adjoining workings, and likewise no one else can break into your workings. Of course, an occasional shot will break through, especially as the surveying is not kept up close (this is a joke, as only Don Luis surveys his mine), but this simply means the building of a wall to separate you from your neighbor, and you continue on your way, and he his.

My mine cost me two dollars, and I am the potential owner of all the silver and tin below, between, around, and above the other miners on the mountain. They only own the ore they have broken down and any block which they have prepared in such a way that I cannot get at it

The Mountain

The Hacienda

without breaking into their workings. Preparing such a block is not very difficult because all I require is to know where it is, in order to drift and cross-cut to it. It is then only necessary to take it out first, to be the owner. So you see, the mountain is really mine potentially with the cubic miles of tin and silver ore which form its base, and which have not been touched! My only problem is to get the ore first.

The plan is to use a two-dollar mine as a basis for promotion and perhaps allow the Socavon, Bebin, and Soux to come in just to make things easier for them. To include them in the promotion is not necessary, as all that must be done is to supply equipment to develop faster than they can. I can thus run circles around them and make their mining unprofitable. This is not theory—it is present practice.

After I have capitalized my mine reasonably along modern lines, I shall have funds for a huge power-plant of Diesel engines, compressors, and drills, and it will be a simple matter to sink faster than anyone else, and stope faster, and thus own Potosi. I will put up a huge mill of crushers, ball-mills, and 500 tables (one of each kind). Why, tin concentrate will be as plentiful as sand, and silver will be as cheap as tears are now in Europe!

Does this sound fanciful? It is exactly what Don Luis Soux is doing on a small scale at the present moment. It is exactly what Bebin Hermanos could do, if they were so inclined. It is precisely what was planned by the originators of the Socavon.

Don Luis told me that he had only located one mine. And he is rated now at—well, he could have helped materially in the over-subscription of the Liberty Loan. The other mines he has naturally came to him by purchase, abandonment, etc.—principally, etc. Don't forget that legally, anything he can take out of the mountain is his, and still there are people—American engineers, geologists, and promoters—who worked hard to change this law! Pressure was brought to bear on the Bolivian Congress and President, urging the good of the country—but it was found to be impossible—on account of vested rights, much as everyone wanted the change made—except the present owners.

If you have grasped the situation, you can realize what an opportunity this is for a Clark or a Jackling, a Gungenheim or a Braden.

Taking all the ore in sight is legal. There are no side-lines, nor end-lines, nor top, nor bottom.

SPELTER imported into China in 1914 amounted to 1,145,600 lb., with an approximate value of \$150,000. Of that amount more than 57% came from Germany and Austria-Hungary, and more than 40% from Great Britain and Hongkong. In 1915 only 36,800 lb., valued at \$15,176, was imported, of which nearly 98% came from Hongkong. In 1916, 87,200 lb. was imported, at an approximate value of \$43,185, and more than 89% of this amount came from Japan. Zinc sheets and plates bought by China in 1914 amounted to 1,229,067 lb., 33% coming from Belgium, 28% from Great Britain and

Hongkong, and more than 17% from Germany. In 1916 this item was reduced to 835,467 lb., valued at \$372,200, of which more than 65% came from the United States, and more than 16% each from Great Britain and Japan. Nearly all dealings with consumers in China are through importing houses, of which there is a large number. American firms generally deal through importers who have connections in the United States, thus facilitating settlements through these connections.

Solder

The highest grade of solder is the eutectic alloy, which contains 66% of tin and 34% of lead. This alloy is expensive, however, and what is known as 'half and half' is the most favored alloy. The presence of a small amount of antimony improves the appearance of solder, but renders it less fluid and impairs its adhesiveness. Some specifications require a minimum of 45% tin and 55% lead, with not over 0.5% antimony. Such an alloy is supposed to be the equal of the regular half and half, and is cheaper. Wiping solder is sometimes made of lead 60% and tin 40%, with a maximum of 0.5% impurity. The regular wiping solder contains about 66% lead and 34% tin. To make the solder from scrap lead and tin, such as old pipe and sheet, the metals can be weighed and melted together in an iron kettle such as is used for making babbitt. The fluid alloy should be thoroughly stirred and can be dipped out of the kettle by iron ladles and poured into strip molds. The metal should be allowed to become rather hot and then stirred for a considerable period with a stick of green wood. The addition of resin and tallow will reduce any scum to dross. When poured into the molds the slower the metal sets the better its surface, therefore marble molds are sometimes used instead of iron.—'Daily Metal Reporter.'

Japanese Sulphuric Acid

Since the beginning of 1917 the price of sulphuric acid in Japan has been steadily advancing owing to increased exports to Russia and China, and also to the Allies for war purposes. As a result, some of the fertilizer companies have reduced their output and have devoted their energies to the manufacture of sulphuric acid, while a number of new companies has been established exclusively for the manufacture of that chemical. The present total output of the country amounts to 582,500 tons per year. Of this quantity, 412,150 tons is consumed by the manufacturers themselves in the production of sulphate of ammonia, hydrochloric acid, and other substances, leaving the remaining 161,150 tons available for general requirements. The domestic demand now amounts to about 100,000 tons per year, so that the quantity for export is about 60,000 tons. It is estimated that the output of sulphuric acid in Japan, if turned out at the present rate, will be in excess of the demand by about 100,000 tons on the return to normal conditions.

Zinc Industry in 1917

According to the best information available to the U. S. Geological Survey the recoverable zinc content of ore mined in the United States in 1917 was about 690,000 short tons, compared with 702,610 in 1916 and 605,915 in 1915. The Joplin area gained nearly 20,000 tons in output. This gain was made during the early part of the year, however, for the increasing cost of operating in the sheet-ground districts, and the declining price of concentrates, caused practically all those mines to close, reducing the output of sheet-ground concentrate from a weekly average of 3000 tons in 1916 to an average of about one-third of that quantity in recent weeks. This loss, which is permanent, involves a net reduction of the zinc resources of the country of over 50,000 tons of recoverable zinc per year, as well as of lead concentrate containing 15,000 tons of lead.

New Jersey increased its output over 10,000 tons, the upper Mississippi Valley region gained 5000 tons, and Arkansas made a creditable increase. Montana fell off nearly 25,000 tons, the loss being due largely to the strike in the Butte district. Colorado lost 10,000 tons. Utah 5000 tons, New Mexico 4000 tons, Idaho and California 3000 tons each, and Nevada 2000 tons. Of the total production, the Eastern States contributed 154,000 tons, or 22%, the Central States 293,000 tons, or 43%, and the Western States 243,000 tons, or 35%; in 1916 the corresponding quotas were, Eastern States, 20%; Central States, 38%; and the Western States, 42%.

The following figures have been compiled, without change, by C. E. Siebenthal, of the U. S. Geological Survey, from reports furnished by all active smelters of zinc ores.

SMELTER CAPACITY REDUCED. Owing to the depression in the spelter industry and to the necessity of curtailing production, two plants in Kansas, one at Chanute and the other at La Harpe, have been dismantled, and nine more plants in Kansas and Missouri soon will be. Twenty zinc smelters were not in operation. The second column in the following table shows the maximum retort-capacity by States before any plants were dismantled.

ZINC-SMELTING CAPACITY RETORTS, 1917

State	Total	Operating		Under construction
		Dec. 15	Dec. 15	
Illinois	47,568	34,232	13,336	...
Kansas	44,054	11,826	29,406	...
Oklahoma	77,899	50,491	27,408	...
Other States	60,090	41,242	18,848	840
	229,611	137,791	88,998	840

Accordingly 88,998 retorts out of 225,637, or 40%, were idle. In a number of cases additions to capacity planned early in the year were abandoned. The only

retorts now under construction are a block of 840 at the Terre Haute, Ind., plant of the Grasselli Chemical Co. The new smelter of the United Zinc Smelting Corporation, at Moundville, W. Va., has two blocks of 1728 retorts completed, but they have not been put under heat. The acid plant, however, is in operation. The smelter and acid plant of the American Zinc & Chemical Co., at Langeloth, Pa., is closed indefinitely on account of a strike. The furnaces and kilns are under repair. Three smelters with acid plants in Illinois are operating at half capacity on account of the difficulty of obtaining zinc concentrate owing to the freight congestion.

PRODUCTION STATIONARY AT LOWER PRICES. The production of spelter from domestic ore in 1917 is estimated at 574,994 short tons, worth, at the average St. Louis spot quotation, about \$102,350,000, and the production from foreign ore was 92,757 tons, a total of 667,751 tons, worth \$118,860,000, compared to a total of 667,456 tons in 1916 (563,561 tons of domestic origin, and 104,005 tons of foreign origin), worth \$178,878,000 at the average St. Louis selling price. This indicates practically the same production as in 1916, but a loss of more than \$60,000,000 in value. Included in the output is 28,175 tons of electrolytic spelter, of which part was refined by electrolysis from prime Western spelter. This was the product of five plants. The quantity of zinc-dust prepared for market was over 7000 tons. The output of secondary spelter re-distilled at regular smelters and at the smelters with large retorts was about 21,600 tons. Primary spelter was produced during the first half of the year at the annual rate of 722,000 tons, during the third quarter at the rate of 626,000 tons, and during the fourth quarter at the rate of 600,000 tons. The production of primary spelter from both domestic and foreign ores, apportioned according to the States in which it was smelted, by six-month periods, was as follows:

SPELTER PRODUCTION BY STATES

State	1916		1917	
	First half	Second half	First half	Second half
Illinois	90,082	90,268	95,149	79,668
Kansas	74,592	65,924	42,359	33,269
Oklahoma	73,298	90,790	109,130	89,389
Other States	78,450	95,054	114,500	104,287
	316,452	342,036	361,138	306,613
	658,488		667,751	

IMPORTS REDUCED; EXPORTS STATIONARY. The imports of spelter (mostly scrap) are estimated at 270 short tons, valued at about \$25,000, compared with 684 tons in 1916. Zinc-dust was imported to the amount of 380 tons, worth \$90,000. The imports of zinc ore in

1917 were approximately 215,000 short tons, containing about 75,600 tons of zinc and worth about \$4,550,000, compared with 385,964 tons of ore, containing 148,147 tons of zinc, in 1916. The imports of zinc ore in the first 10 months of 1917 originated as follows:

IMPORTS OF ZINC ORE, JANUARY TO OCTOBER 1917

From	Ore short tons	Zinc content short tons	Value
Canada	14,554	4,362	\$ 294,669
Mexico	130,090	41,853	2,574,129
Spain	14,778	6,083	260,922
Italy	5,919	2,411	117,271
French Africa	1,246	623	66,346
Australia	27,731	12,502	753,598
	194,318	67,834	\$4,066,935

Exports of spelter and sheets made from domestic ore are estimated at 144,000 short tons, worth \$37,000,000, compared with 163,137 tons, worth \$51,312,990, in 1916. Exports of spelter made from foreign ore are estimated at 60,000, valued at \$11,900,000, compared with 43,230 tons in 1916. The exports of zinc manufactures fell off to \$400,000 in 1917 from \$572,286 in 1916. The exports of brass are estimated at 169,000 tons, valued at \$104,300,000, compared with 122,466 tons, worth \$72,683,626, in 1916. Manufactures of brass were exported to the value of about \$134,500,000, compared with \$241,668,081 in 1916. The value of loaded cartridges exported in 1917 was about \$41,000,000, against \$55,103,904 in 1916.

CONSUMPTION AND STOCKS. The apparent domestic consumption of spelter in 1917 may be computed as follows: The sum of the stock on hand at smelters at the beginning of the year, 17,598 tons, plus the imports, estimated at 270 tons, and the production, 667,751 tons, gives the total available supply, namely, 685,619 tons. From this are to be subtracted the exports of domestic spelter and sheets, 144,000 tons; the exports of spelter made from foreign ore, 60,000 tons, and the stock on hand at smelters on December 5, of 50,107 tons, or a total of 254,107 tons, leaving a balance of 431,500 tons as the apparent domestic consumption. This calculation takes no account of stocks of spelter held by dealers or consumers. This shows a decrease of 23,000 tons from 1916. The normal ante-war consumption of spelter in the United States was about 300,000 tons. The stock of spelter on hand at smelters, in transit, or in the hands of agents December 15, 1917, was 50,107 tons, as compared with 17,598 tons on hand or in transit January 1, 1917, with 33,147 tons June 30, and with 47,186, September 30.

DECLINE IN PRICE. The price of spelter at St. Louis started at 9.75c. per pound, and after receding to 9c. at the middle of January rose gradually to 10.75c. early in March. The price dropped to 8.9c. late in April, rose gradually to 9.4c. by the end of May, but, in a series of declines, with short recoveries, reached 7.75c. near which it closed the year. The average quoted price for the year for prime Western spelter at St. Louis was 8.9c. per pound, as compared with an average sales price for all grades of 13.4c. per pound in 1916, and 12.4c. in 1915.

E Determination of Sulphur in Pyrite

*The following modification of Lunge's method is recommended. Place 1 gm. pyrite, finely ground and sifted, in a porcelain crucible; treat with 20 cc. HNO_3 and 5 cc. HCl ; cover with a watch glass; allow to react at the ordinary air temperature, and when no more nitrous fume is given off, evaporate on a water-bath to dryness; add 5 cc. concentrated HCl ; again evaporate to dryness and add 100 cc. distilled water and 1 cc. concentrated HCl ; precipitate the Fe with 10 cc. NH_4OH (d.o. 91) and heat the whole at 60 to 70°C. for 10 min.; the Fe separates out completely. Decant the solution, wash with boiling water so that the filtrate may amount to almost 250 cc.; cool, and make up to 250 cc. (solution A). Remove the preparation from the filter by means of a spatula (without breaking the filter); place in the same crucible as before, and dissolve in the least possible quantity of concentrated HCl . Pour the liquid upon the same filter, and collect the filtrate in another 250 cc. flask, using a few extra drops of acid. Thoroughly wash the crucible and filter with boiling water so as to fill the flask about one-third full. Re-precipitate the Fe in the solution with 10 cc. NH_4OH (d.o. 91); cool, and make up the solution to 250 cc. (solution B). Take 100 cc. of solution A and 100 cc. of solution B, in a beaker; neutralize with diluted HCl , using methyl orange as indicator; and 1 cc. concentrated HCl ; boil, and add 100 cc. boiling 2% solution of BaCl_2 at one time. Let the preparation stand one-half hour; decant, add 100 cc. boiling water; allow to settle, and filter. Repeat this three or four times, continuing the washing until 5 cc. of the filtrate will give no precipitate with H_2SO_4 , nor even a turbidity. Dry, ignite as usual, and weigh.

ZINC OXIDE, a white powder, which is manufactured on a large scale in New Jersey, has an important use in the rubber industry in addition to its use as a pigment in the paint industry. It is employed to increase the tensile strength of manufactured rubber. According to one authority, a mixture of pure rubber, after being vulcanized with sulphur, has a tensile strength of about 2000 lb. per square foot and an elongation of 960% of its original length. The effect of adding zinc oxide is to increase the tensile strength but to diminish the elongation, as shown by the following table:

Zinc oxide %	Tensile strength	Elongation
	Lb. per sq. ft.	%
25	2400	720
35	2400	700
45	2700	680
55	2500	620
65	2000	540
75	1300	400

It will be seen that up to about 60%, zinc oxide increases the tensile strength of rubber. This effect is said to be greater than that obtained with other mineral fillers. Lithophone is its chief competitor.

*Abstract: C. Zay, Staz. Sper. Agrar. Ital.; XLIX, 530; 1916.

Mining in Colorado

By ARTHUR J. HOSKIN

January shows what will probably prove the lowest point of this winter's mining activities in Colorado. The unusually mild weather prevailing in the State during the early part of the winter permitted operations at many alpine mines that generally close down in October or November. The season for all such properties was, however, effectually closed soon after New Year's day and miners are guessing whether the spring will come earlier or later than usual. Reports are already coming in regarding the running of snowslides, the toll including two miners in the San Juan region. Cripple Creek suffers the least, among Colorado mining districts, from wintry conditions; and this month's production will probably show up better than corresponding outputs for several years past.

The Derry Ranch Gold Dredging Co. maintained steady dredging activities until December 15. This is the company that, late in the summer of 1916, erected a dredge on a hay-field between Leadville and Twin Lakes, working two months that first season and about six months during 1917, recovering sufficient gold within the first three operating months to amortize the entire investment in land and equipment. The holdings comprise about 1800 acres, although no claim is made that the pay-channels cover more than a small fraction of this acreage. The ground that has been worked and that was selected as the best has shown recoveries varying—during monthly runs—from 20 cents to 50 cents per cubic yard. The 1917 production of gold by this company is said to have averaged \$15,000 per month.

Attention among mining-men just now is divided between two comparatively new Colorado industries, each of which shows signs of permanence. These industries are the mining and concentration of molybdenum ore and the excavation and distillation of oil-shale. Several substantial close corporations are conducting research to decide upon means for making best profits from the oil-shale deposits in western Colorado. There are numerous other companies that will probably never get beyond the stock-peddling stage for the reason that they are not fostered by men possessing the ability or the notion of legitimately conducting such enterprises. There have been so many fake oil-company promotions in Denver during the past year that investors pay little heed to oil-shale promoters and the expectation among disinterested persons is that most of these weak concerns will not survive the winter or be in shape to proceed commercially when the spring drive starts. This is not written to belittle the oil-shale industry. On the other hand, the opinions of the Government and State geologists concerning these tremendous resources are in accord. There

can be no doubt that success will attend those companies that have the means, the technical staff, and the management to push development of properties and the erection of plants on the necessary scale. Several inventors are developing processes for distilling numerous valuable hydrocarbons from these shales and recovering by-products such as ammonia and potash. Two such inventions have been definitely selected by some of the substantial oil-shale companies, these processes being known as the Galloupe and the Chew, from the names of their respective inventors. Other companies intend to install the Scotch process. Very little is being accomplished upon the ground for the reason that it is blanketed by two to four feet of snow. Engineers for several Eastern investors are awaiting the favorable season for making investigations.

The other new industry referred to is that of molybdenum mining and reduction. It is true there has been more or less work of this kind in Colorado for years past and that the Primos Chemical Co. undertook to conduct molybdenum mining upon a commercial scale three years ago in Clear Creek county; but, for various reasons, the chief of which was litigation, the industry has not thrived. The Primos company is credited with having mined, during 1917, molybdenum ore having a gross value of \$250,000 and it is said that in 1918 production bids fair to be considerably greater. About two years ago an attempt was made to commercialize certain great masses of low-grade molybdenite ore occurring on the crest of the continental divide close to Fremont Pass and the line between the counties of Summit and Lake, at the station of Climax on the South Park branch of the Colorado & Southern railroad. A shipment of 1000 tons of this mineralized porphyry was made to Leadville—a few miles south—and sampling proved its molybdenum content to be 1.14%. At that time, however, sufficient interest could not be aroused by the promoters of the project to secure the capital needed for a plant. At that time the concentration of molybdenum ore had not reached the degree of perfection that stands back of the present interest in this business. Two companies have secured large holdings at Climax and have erected milling-plants. One of these, the Molybdenum Products Corporation, is to use a process of concentration developed by M. S. MacCarthy, of Denver, and it has shown remarkable progress in its mining development and plant erection despite many obstacles arising from war's disturbance to delivery of machinery and supplies. The first unit, which is practically completed, has an estimated capacity of 100 tons, but it is so planned as to admit of easy enlargement. An aerial tramway has been

erected to transport the ore from its source above timber-line down to the mill, which is beside the railroad a few feet below timber-line. Details of the MacCarthy process are not available, but it is said to involve new principles in concentration, to operate inexpensively, and to produce high-grade concentrate at one operation. The concentrate will be reduced in another plant owned by the same company in Denver.

The mining of molybdenum has aroused new interest also in that portion of Gunnison county tributary to the town of Pitkin. As yet but one concern is producing from the fissure deposits, this being a partnership comprising William J. Candlish, C. E. Savery, and William E. Cramer. A large amount of run-of-mine from a 12-ft. vein has been shipped to Denver, where it is being concentrated in a small experimental plant designed especially for this purpose. The raw ore is white massive hard quartz, the molybdenite occurring along myriad fractures and in vugs. The ore runs about 4% molybdenum. Treatment in this mill involves crushing, ball-mill grinding, and oil-flotation in a six-cell Ruth machine.

The Colorado Metal Mining Association and the Colorado chapter of the American Mining Congress are holding a joint annual meeting this week in the Capitol building. The sessions draw good audiences. Among subjects up for discussion are the Federal establishment of a price for silver, oil-shales, and the re-opening of the withdrawn oil-lands of the West. Senator Key Pittman of Nevada spoke interestingly upon the last subject. Governor Emmett D. Boyle of Nevada handled the silver question in a scholarly address that advised the mining men to boost for the last bill that has been introduced at Washington, notwithstanding the objections that may be entertained by Westerners. The subject of oil-shales was covered by Dr. David T. Day of the U. S. Bureau of Mines. Other speakers include Fred Carroll, State Commissioner of Mines, Senator J. B. Kendrick of Wyoming, Bulkeley Wells, D. A. Lyons of the Bureau of Mines, and Dr. R. D. George, State Geologist of Colorado. An incident of the first day's session followed the reading of a paper written by Victor C. Alderson on 'The Experimental Plant at the Colorado School of Mines.' The discussion following President George M. Taylor's reading of the paper took the form of decided criticism of the manner in which the affairs of the school have been mismanaged during the past year, with special protest against the usurpation of the presidency by Dr. Alderson, whose masterpiece, the experimental plant, was declared fit material for the junk-heap. Arguments were presented urging the removal of the school from Golden and making it a department of the State University at Boulder.

SULMAN AND PICARD have patented a method of extracting lead from ores, consisting of bringing the lead into the form of a sulphate by a suitable roast, and dissolving it with a solution of common salt. The

lead is then precipitated from the filtrate by sodium carbonate. Zinc present in the calcine as sulphate is also dissolved, and in the process of precipitation the lead is thrown down first with a weak solution of sodium carbonate, while the zinc remains in solution. The addition of a further amount of the sodium carbonate will then precipitate the zinc. A variant upon this procedure is to leach the zinc oxide and sulphate from the calcine with dilute sulphuric acid, and then treat the residue with salt-solution to recover the lead.

Wolframite in Argentina

One of the important wolframite deposits of Argentina is in the Province of San Luis, which lies between the Provinces of Córdoba and Mendoza, in the west-central part of the Republic. A detailed account of the deposit is given in Boletín No. 3 of the Dirección General de Minas, prepared by Roberto Beder. The ores are associated with magnetite in quartz pegmatite veins traversing crystalline schists on the western slopes of the Cerro del Morro. The schists have been identified as belonging to the lower Silurian, and they have been disturbed and altered by intrusion of granite, followed by andesitic eruptives. The acidic intrusives cross the schistosity of the overlying formation, for the most part having a north-northeasterly course. They consist of aplite, pegmatite, micaceous quartz dikes, together with dikes of pure quartz and some with tourmaline. No basic dikes are found with these acidic intrusives. The wolframite is found in the micaceous quartz dikes, and some of the pegmatites contain large amounts of magnetite and martite. For the most part the iron is present as martite, which is pseudomorphic after magnetite. The wolframite veins are from two to four feet wide, but the quantity of tungsten mineral bears no relation to the width of the quartz masses. It is most abundant in the quartz, and is not associated with the mica. It is gray to yellow and brown in color. The distribution of the wolframite is irregular, and in the richer deposits will not exceed 1 to 1.25% of the ore. Generally these enriched portions do not extend more than six to twelve feet along the length of the dikes. Apatite and fluorite are fairly abundant as accessories. Other occurrences of wolframite are known in the Sierra de Córdoba, which have been described by Bodenbender in a bulletin on the mineralogy and mining of that region issued by the Argentine bureau of mines in 1905.

PYRRHOTITE deposits, containing 42 to 50% Fe, and 26 to 35% S, are found in the State of Maine. At the Katahdin iron mine, after having utilized the oxides in the gossan as an iron ore, the pyrrhotite was found beneath, and the deposit, as now developed, shows about 5,000,000 tons. The length of the orebody is 2300 ft., the width varies from 300 to 700 ft., and the lower workings are in pyrrhotite of undiminished grade.

REVIEW OF MINING

NEW YORK

COAL AND ICE SHORTAGE.—GAS PRODUCTION.—FREIGHT MOVEMENT.—SHAREMARKETS.—FOOD PRICES.—LABOR.

As New York is the vital centre of the United States, the following observations should be appropos:

The second heatless holiday, affecting about 2,000,000 wage-earners and an army of salaried officials, was characterized by the same apathetic compliance with the new regulations that marked the observance of the previous 'blue' Monday. The outlook remains the same, with no visible relief in sight. Coal receipts are not up to expectations. Additional cold spells are making harbor conditions worse, and piling up difficulties in the way of any immediate realization of hopeful prognostications. Landlords are not losers by the new regulations, and with increased rents and prompt compliance with patriotic appeals to reduce coal consumption to a minimum they manage to consider everybody but their unfortunate tenants. That the present tie-up was fully anticipated by those who had studied the problem of supplying New York's daily needs is seen in the fact that as far back as 1903 it was suggested that an immense storage-yard should be provided in the New Jersey meadows, and that this should be connected by tunnels to New York City and Brooklyn. For next winter it is proposed to store 500,000 tons of coal on Staten Island in the harbor. The cost of the scheme was against its adoption but had steps been taken along those lines, and the present crisis passed without recourse to the drastic methods now in vogue, the preliminary expense would have been more than justified. The great service corporations in New York operate on the 'hand to mouth' principle with reference to coal supply, and this fact was brought home to the public in a realistic fashion last August when the arrival of a coal-barge at the wrong wharf caused a tie-up of the Interborough Transit Co. system and inconvenience and loss to hundreds of thousands of persons. The prospect of success in a gamble which views with complacent optimism the possibility of a mild winter or a cool summer in New York is indeed small.

Ice is just as much a necessity in the summer months as fuel is in the winter. A warning has already been sounded that there will probably be a rise in price of this commodity, with every prospect of a serious shortage as soon as consumption increases. There are economic difficulties in the way of harvesting a sufficient supply of the natural ice of the Hudson river at the present time. Labor is expensive and storage facilities are lacking. The controlling companies are also disinclined to cut any more ice until they are certain of the market. The supply of the artificial product may be considerably curtailed if the Government follows its proposed intention of controlling the production of ammonia for munition and other war purposes. Like the coal shortage, the ice situation will doubtless receive due attention in the proper season.

The prospect of efficiently operating the industrial mechanism of New York under existing conditions is as feasible as trying to run a reduction plant without ore-bins. The only attempt made to provide against abnormal conditions must be credited to the gas companies who for several weeks past have been selling \$30,000 worth more gas daily than they did during

a similar period last year. Had it not been for this reserve the suffering would have been still more acute; and the new Tammany Mayor threatened to seize this stock which kept the people warm by producing gas! There is, however, another side to the question. Gas-heating appliances consume much air and produce a vitiated atmosphere. Absence of ventilation has been the cause of much sickness and generally unhealthy conditions, a state of affairs fostered and encouraged by "A message to householders from the United States Fuel Administrator," in which the following unhygienic methods are enjoined: "Do not cool off house by opening windows;" "Weather strip your windows or stuff cracks with cotton." As the building laws have apparently never considered it worth while to insist on efficient ventilation, the effect of hermetically sealing living and sleeping rooms in an effort to carry out the Fuel Administrator's wishes can only result in an appreciable lowering in the stamina of the people, with a still greater prospect for the effective spreading of infectious complaints.

A prominent New York business-man has made the following suggestions to Mr. McAdoo to relieve the freight congestion in and around the city:

"Define and establish sites for the erection of sidings on all main railroad lines as ready-freight yards, approximately one hour's freight distance from terminal and seaboard points.—Build on such sites railroad sidings arranged for ready-freight sheds, with railroad track on one side and wagon road on the other side.—Build trackside ready-freight sheds.—Cantonment camp builders to erect sheds.—Place such sheds under military guard.—Whenever necessary, during labor shortage, with the co-operation of the nearest military forces, detail the needed number of soldiers to load and unload, following the precept of foreign countries in this respect."

He claims that the adoption of the scheme will cure the present congestion and that if the plans are carried out:

"They will save daily thousands of car-days.—They will clear the tracks for food, fuel, and priority freight.—They will guarantee the necessary speed for the movement of goods abroad.—They will prevent the interruption of domestic business.—They will speedily eliminate the necessity for embargoes.—They will collect merchandise for home industries at points reasonably available at terminal cities."

Public confidence is usually reflected in the condition of the sharemarkets, and the hardening of prices during the past week may be attributed to the fact that a feeling of relief is prevalent that the most drastic step that could be taken is now a matter of history. The public may be forgiven for a complacency which assumes that the worst is over.

New York newspapers have acted in harmonious unison in raising the price of their evening papers to two cents per copy. The sole exception is the 'Evening Post,' which is reduced from three to two cents—a progressive step which places a journal of high standing within the reach of a wider circle of readers. The increase in price of the other papers led to an immediate though ill-organized strike of dealers who objected to being excluded from a share of the spoils. The strike has fizzled out without the granting of concessions, and the dealers must be content with their previous profit of 40c. per 100 copies.

From across the water comes the news that the British Food Controller has been able to reduce the price of 13 out of 21 prime necessities. In view of the ever-increasing cost of existence in New York this is almost unbelievable. Rumors of fresh restrictions in the way of meatless days and wheatless meals are afloat, but the price of necessities has risen to an extent that the bulk of the people do not view them with any apprehension, since the time has long since passed when it was possible to afford meat on those occasions when its use was not prohibited. The new war loaf promises to be a dearer article than its predecessor, as the substitutes for wheat to be used in its composition are all higher in price than the wheat itself. A reduction of one cent per quart in the price of certain grades of delivered milk will only affect a section of the community, as the majority has adopted the 'cash and carry' plan to avoid the exorbitant cost of the delivered article.

Extensive damage is still being done by incendiaries who have been paying special attention to war materials' factories in the vicinity of New York. An interesting conclusion from primary investigations shows that these outbreaks have been caused for the most part by the radical anti-war element rather than by alien enemies. The difficulties in the way of preventing similar outbreaks in the future are therefore rendered increasingly difficult.

New York's snowfall, which shows an almost daily increment, calls for a force of about 14,000 workers per shift to effectively cope with the situation. There is a serious shortage of labor, with the result that many of the Dutch sailors from the ships now lying idle in the port are among the helpers.

TONOPAH, NEVADA

TONOPAH MINING.—TONOPAH EXTENSION.—TONOPAH BELMONT.—WEST END CON.—MACNAMARA.

The Tonopah Mining Co. shipped 20 bars of bullion, valued at \$40,000. The total earnings of the Tonopah property and all the subsidiary properties for the quarter ended November 30 was \$181,788. During the past week 2660 tons of ore was milled averaging \$5.50 per ton. The low average value of the ore milled at Millers is due to the fact that the plant operated on ore from the old dumps. At the Silver Top 45 ft. of development has been done and 37 ft. at the Sandgrass. On the 440-ft. level of the Silver Top the cross-cut in the foot-wall of the Valley View vein is being continued. A number of stringers of good ore has been cut. On the 540-ft. level stoping has been started on the Beta Fault vein. At the Mizpah shaft on the 600-ft. level stoping has been confined to the pillars on the Mizpah vein. Work has been resumed in the north drift on the 1300-ft. level of the Sandgrass. The west drift continues in fault material and the vein has not yet been cut. Last week's production was 3850 tons.—The Tonopah Extension Mining Co. shipped 22 bars of bullion, valued at \$45,000. At the No. 2 shaft 58 ft. of development has been done and 185 ft. at the Victor. At the No. 2 shaft raise No. 469 on the 1260-ft. level is in a 2-ft. face of ore. Raise No. 472 is advancing on a 2-ft. face of low-grade ore. At the Victor on the 1540-ft. level raise No. 1614 advanced 43 ft. on a face of low-grade ore. The intermediate from the 1501 winze advanced 14 ft. on 5 ft. of ore on the Murray vein. On the 1680-ft. level west drift No. 1600 advanced 31 ft. on low-grade quartz. The south cross-cut has been extended beyond the O. K. vein. The foot-wall branch of the Merger vein is called the Victor vein. The production for the past week was 2380 tons.—The Tonopah Belmont Development Co. shipped 53 bars of bullion, valued at \$100,000. On the 800-ft. level raise No. 19 from the Occidental vein continues to advance on a 6-ft. face of good ore. Raise No. 20 on the same vein shows a 5-ft. face of ore. East drift No. 8021 on the Occidental vein cut a fault and a cross-

cut has been started to pick up the faulted segment. On the 900-ft. level raise No. 47 has been started on the South vein exposing 2 ft. of medium-grade ore. Raise No. 48 on the branch of the Rhyolite vein shows 1½ ft. of ore. West drift No. 1146 on the Mizpah Fault vein shows 2 ft. of medium-grade ore. Last week's production was 2455 tons. The Belmont Wagner Mining Co., a subsidiary of the Tonopah Belmont, has been actively engaged on preliminary work on the mill. The mill will have a daily capacity of 300 tons and will be in operation by March 1. All the necessary office buildings and houses have been completed. The Alta properties of the Belmont company consist of 2000 acres of mineral land, near Telluride, Colorado.—At the Ohio shaft of the West End Consolidated Mining Co. drift No. 535 has been discontinued. Winze No. 534 has a total length of 100 ft. and continues in fair ore. Raise No. 528 is making fair progress in a good grade of ore. Drift No. 539 has been started. On the 555-ft. level raise No. 5 continues in low-grade ore. Cross-cuts No. 3 and 5 have been started. Raise No. 814 reached the hanging wall of the vein, and 601 drift has been started from the raise to the north to explore the vein. At the West End raise 623 No. 1 made a connection with 623 stope No. 7, and stoping has been started from the raise. The new cross-cut No. 809, which is being driven toward the Ohio territory, made good progress. The output last week was 978 tons. At the Halifax Tonopah drift No. 1019 continues on a high-grade stringer. Raise No. 1020 on the same stringer shows high-grade ore. On the 1200-ft. level cross-cut No. 1256 shows silicification. The 1708 cross-cut has been unable to advance on account of heavy ground. The production last week was 51 tons.—On the 300-ft. level of the MacNamara Mining Co. stoping is confined to the hanging wall and the foot-wall of the old stopes. On the 700-ft. level west cross-cut No. 700 advanced 25 ft. Intermediate drift No. 1 on the Ohio vein advanced 20 ft. on a 5-ft. face of ore. The production last week was 343 tons.—Good progress is being made in the new cross-cut on the 1100-ft. level of the Rescue Eula. A raise in ore from the 1050-ft. level is being driven for a connection with the 950-ft. level.—At the Wandering Boy shaft of the Jim Butler Tonopah Mining Co. raise No. 374 on the 2nd level advanced on a 4-ft. face of ore. Repair work has necessitated slowing down development work. The output last week was 397 tons.—At the Monarch Pittsburg raise No. 815 from the 850-ft. level has reached an elevation of over 200 ft. vertically. The raise is being continued; a 650-ft. level will soon be started. The present face shows considerable quartz and conditions are such that the extension of the Ohio vein might be cut.—At the Cash Boy on the 1600-ft. level 17 ft. of ore was penetrated. Of this, 12 ft. assays \$30 per ton. Work is being continued on the 1700-ft. level but a lack of cars has curtailed the output.—The Montana produced 204 tons of ore and miscellaneous 43 tons, making the week's production at Tonopah 10,701 tons with a gross value of \$181,917.

OATMAN, ARIZONA

GOLD PRODUCTION.—GOLD ORE.—TOM REED.

Oatman produced just about one-half the gold mined in the State of Arizona during 1917, according to the figures compiled by the U. S. Geological Survey. The State is credited with a total production of \$4,831,000 of which the two Oatman producers contributed \$2,400,000. The gold production of the State increased \$900,000 during the year, Arizona being the only State in the Union to register an increase in gold output as compared with 1916. The credit of this increase is due the United Eastern, which added \$1,850,000 to the State's total, there having been a considerable decrease in the amount of gold taken out by the copper mines of the State. The Tom Reed's 1917 production was approximately \$550,000, an in-

crease of about \$75,000 over 1916. According to the statistics compiled by the Geological Survey, Oatman's gold production was the largest ever attained by the district, being nearly three times the output of 1916, which is given as \$850,000. That year was the lowest during the past decade, activities being confined to development rather than production; the Gold Road having only operated for half the year at a greatly reduced capacity. In 1915 the mines of the district produced \$1,626,437 in gold, in 1914 \$1,891,214, in 1913 \$1,874,547, in 1912 \$1,899,131. The present indications are that 1918 will register a decided increase over any previous year.—It is safe to predict an additional production from the United Eastern, as this great mine has been proucing at the rate of \$2,100,000 for the last six months of 1917. The production of the Tom Reed should at least equal that of 1917, and the Gold Ore will be producing shortly. The possibilities of gold production at the Gold Road mill, now operated by the Gold Ore, are two-fold. From the Gold Ore mine a daily production of 100 to 200 tons per day is planned, and if this ore holds up to the average milling returns shown by the 2000 tons shipped to the same mill in 1916, this should mean an output in bullion of \$45,000 to \$90,000 per month. In order to provide a continuous supply of ore, active developments will be carried on by the Gold Ore management after production begins. The orebody opened by the original shaft 1500 ft. east from the present workings will be thoroughly explored. This old shaft is over 200 ft. deep and several hundred tons of ore was taken out of it and shipped to the Gold Road mill during its progress to that depth. There is also a strong possibility that ore from the Line Road adit workings of the Gold Road Mines Co. may be treated at the Gold Ore mill. High officials of the U. S. Smelting, Refining & Mining Co. have intimated that such was a possibility. A large body of ore running from \$15 to \$25 per ton is being opened by the Gold Road. While the vein is only about four to five feet wide, it is being explored by drifts in two directions and by a winze which is being sunk from the lower level. An entirely new mill to treat the ore from both the Gold Road and the Gold Ore properties is also within the range of possibilities. It is the policy of the U. S. Smelting, Refining & Mining Co. to handle custom ores, and the Gold Road Bonanza may also find an outlet for its ore here if developments place this property upon a producing basis, as present indications promise.—Oscar H. Hershey, of the Bunker Hill & Sullivan Mining Co., is now making a third exhaustive examination of the Tom Reed property with a view to future developments in the Gray Eagle and Bald Eagle sections.

Developments at the Oatman United recently have created unusual interest. The east cross-cut has opened up a vein four feet wide carrying considerable quartz and the drift along the west vein is getting into a formation showing an increased proportion of quartz showing gold. At the Record Lode, the drift along the vein to the west is opening up solid vein-matter consisting largely of quartz that assays well.

TORONTO, ONTARIO

BRITISH AMERICA NICKEL—HOLLINGER CON.—PORCUPINE CROWN.
KIRKLAND LAKE, TEMISKAMING.

The British America Nickel Corporation has decided to abandon the proposed site of its large refinery near the Murray mine in the Sudbury district, on account of the difficulty of obtaining power. The project of developing electricity at the French river, the nearest available point, was dropped as being too costly, the revised estimates placing the cost at \$46 per horse-power. The corporation will probably build the refinery at some point near Ottawa where a supply of power at a reasonable rate is assured. The construction of the smelter and the development of the mine are being energetically carried on by

a working force of about 400 men. The ore-reserve is being steadily increased and is now estimated at 15,000,000 tons.—The present year promises to be one of great activity in Porcupine and the other northern Ontario gold camps. Operations at the Dome Mines, which have been suspended for some time, will be resumed shortly by the E. J. Longyear Co., which has contracted to put down No. 3 shaft to the 1500-ft. level. This company has been doing shaft sinking and exploration work in the Sudbury district for two or three years with marked success.—The Hollinger Consolidated has tried out the first

PART OF ONTARIO, SHOWING SUDBURY, COBALT, AND PORCUPINE

unit of its new equipment consisting of 20 stamps, which proved satisfactory. This will, for the present, take the place of a similar section of the old equipment, which will be closed-down, as the scarcity of labor prevents an increase in the volume of work. A greater output, however, is anticipated on account of the improvement in the grade of ore recently developed, which should increase the value of the mill-head.—At the Vipond-North Thompson the 100-ton mill is running close to capacity, with a recovery averaging \$8.50 per ton.—The annual statement of the Porcupine Crown for 1917 shows a marked decrease in production with an output of \$364,703 as compared with \$575,604 in 1916. The profits for the year were \$109,421 as against \$270,430. The decline was caused by a cave-in at the mine during April, which hampered operations for some months. The ore-reserve is estimated at \$60,000 tons, valued at \$610,000.—At the Dome Lake good ore is being found in No. 3 vein in a slope from the 400-ft. level. The shaft is being put down from the 400 to the 500-ft. level.—Arrangements have been completed for the resumption of work on the

Thompson-Krist which will be carried on by the Vipond-North Thompson from the 400-ft. level of its property.

The Lake Shore of Kirkland has cut the No. 2 orebody on the 400-ft. level under the lake. The width of the vein where cut is about 22 ft. and the greater part of the ore will average about \$8 per ton, with streaks carrying considerably higher gold content. The company's new mill is expected to be completed by the middle of February.—The mill of the Teck-Hughes is being overhauled and a number of improvements made to increase its capacity and improve the recovery.—At the Wright-Hargraves No. 3 shaft has reached the 200-ft. level and cross-cutting has been started. The cross-cut has passed through 16 ft. of the vein and is still in ore.—The Nipissing company is discarding the Callow oil-flotation process in favor of the cyanide treatment. Among the reasons assigned for the change are the high cost of the flotation process and the difficulty of marketing the product, which at present has to be shipped abroad for treatment. Threatened litigation over the right to use the flotation process has no doubt influenced the decision. By the use of Wilfley tables, followed by cyaniding, it is possible to produce a concentrate which can readily be turned into bullion at the company's Cobalt refinery.—The feud between the Morgenstern interests and the administration of the Temiskaming company, which has been fiercely waged for some time, appears to be decisively settled in favor of the present Temiskaming officials. A recent shareholders meeting showed that the latter held a good majority of proxy votes. Sir Henry Pellatt, a prominent Toronto financier who was expected to become president, has declined the office, but threw his influence in favor of the present board, who in all probability will be sustained at the annual meeting on February 4.—At the Gifford a 10-in. vein showing good silver content has been cut at the 350-ft. level. The cross-cut is being run toward the Beaver to cut three intervening veins.—The annual financial statement of the Crown Reserve showed ore production of the value of \$265,155, against \$191,822 for the preceding year, and net profits of \$82,573.—The shaft on the Violet property of the La Rose Consolidated is down 400 ft. and will be sunk 30 ft. deeper. From this point a cross-cut will be run to pick up veins which are believed to come in from the O'Brien mine.

HOUGHTON, MICHIGAN

CALUMET & HECLA.—RAILWAY SERVICE.—ISLE ROYALE.

The discovery of the Calumet conglomerate lode, its enormous output of copper, the millions spent for labor and operations, and the millions it produced in dividends to the shareholders, has, for years, been looked upon as rarely equalled in the history of mining. It is now 15 years since the then best known publicist in the copper mining world announced that the Calumet conglomerate lode gradually was losing hold, gradually was becoming less and less an important factor in the world's copper production, and that the end of the mine was in sight. Still, owing to careful management, the Calumet conglomerate lode continues to be an enormous factor in the total output of the Calumet & Hecla copper mine, and the conglomerate lode furnishes more copper each year from the old lake sands that are being re-treated.—That the Franklin could keep alive and continue its openings and not lose money with the present high cost of mining and the control of the price at 23½c. is one of the creditable showings of the management. But Franklin not only is making a little profit right now, but it is going ahead with development work that seems to assure the future success of the mine. No. 1 shaft is down 3700 ft. All the levels run 800 ft. in each direction. The 27th and 32nd run all the way over to the expectant cut of No. 2 when it reaches that depth, namely 1600 ft. The other levels

are all in good average ground. No. 2 shaft is down 50 ft. below the 17th level. No more cross-cuts will be run from this shaft, but it will be sunk straight down for a distance of 500 ft. The mine management has proved the ground at that depth. This sinking will be continued with all possible speed to cut the 27th level from No. 1. Under the unusual difficulties of a bad winter, Franklin is maintaining a production of 1150 tons of ore daily, and sometimes it runs as high as 1500 tons. This is the best average the mine has been able to keep up for any long period. Four haulage systems are working satisfactorily underground, and the intensive mining plan of having four or five drills operating in the same vicinity is working satisfactorily. A fifth haulage system is being installed. This will prevent interruption of ore shipments, as it will provide one additional haulage system for emergency purposes. Formerly when any break happened to one system there immediately came a 25% falling off in ore production. Franklin has 285 men on its force, and needs more trammers and miners. At the mill six new Wilfley tables are being installed for the re-grinding plant. A Hardinge mill has arrived, but there is little expectation of operating it for five months, owing to the difficulty of securing a motor. Franklin, perhaps the lowest-grade mine in the district, is keeping its head above water because it has the best of management and the most loyal working force ever secured at the property.—At the Mohawk shafts 4, 5, and 6 are showing a better grade of copper ore, the average for all three being 21 lb. per ton. No. 1 is in very poor quality of ore. No. 2 is still closed because of lack of labor. Motor haulage has been ordered but deliveries are not expected for months.—At White Pine Extension the north and south drifts from 2nd and 4th levels continue; the drift is in 800 ft. and south 1100 ft.; in No. 2 shaft the ore is running 25 lb. of copper per ton.—The Seneca is experiencing considerable difficulty in re-building the blacksmith and machine shops that were destroyed by fire last week. Shaft-sinking will be delayed several weeks longer.—The Osceola is producing 5000 tons daily.—If the Government of the United States wishes to learn how to handle railway service during severe storms and extreme cold weather the best place to take lessons is right here in the Michigan copper country. Practically all railway trains are completely hidden by deep banks of snow on either side of the tracks.

There is a general acknowledgment among mining men relative to the geology of the Isle Royale and its comparative formation across the lake at the Quincy and Hancock mines. The West lode, or Grand Portage, instead of being a separate formation from the Isle Royale lode proper now is looked upon as part and parcel of the main lode, simply branching from it or separated by a fault. In the Hancock Consolidated there is no doubt that the various formations which have produced and now are carrying copper are in realization all part of the same mother lode. Isle Royale mine continues to increase production steadily. The property must be operated on an enormous tonnage to make it pay decent returns to the shareholders. The company now has double the stamp-mill equipment that it formerly had, owning three of the new heads at the Point Mills plant in addition to the three heads in the main Isle Royale mill nearer the mine.—Wyandot has shipped ten cars of copper ore to the Winona mill for treatment. Six more cars likely will go this week. The ore is taken from the tenth level stope, is not selected, and to look at it one would not suppose there could be any copper in it. However, the returns from the mill are more than paying expenses and, in the meantime, the developments are encouraging.—While there are no startling evidences of betterment in Hancock Consolidated, the fact is that underground the showing is maintaining its average and the work is being laid out so that a larger ore tonnage can be established and maintained.

THE MINING SUMMARY

ALASKA

Reports come from Kuskokwim that good pay-ore has been struck on Moore creek. The defunct American Bank of Alaska, at Fairbanks, owns a number of claims on this creek; these fell into its hands for money loaned, and it is thought that the pay-streak, which was discovered on a claim adjoining the bank's property, runs through two of the claims owned by the bank.

The last of the big steel tubes for airducts to be used in the Alaska-Juneau mill for heating it with hot air are being turned out at the Treadwell machine-shops where Gilbert Walsh, the foreman of the boiler-makers, and Charles Price, of the tinsmith and plumbing departments, have been busy on the pipes and tubes for the past three months. The final sections will be completed and sent to the Alaska-Juneau within the next few days, after which the latter plant will be heated by the new process.

ARIZONA

MARICOPA COUNTY

(Special Correspondence.)—A mining deal said to involve a large sum of money is now being negotiated in the Tiptop district between S. J. Tribolet, principal owner of the Kay Mining Co., and George W. Long, one of the principal owners of the United Eastern gold mine at Oatman. The Kay mine, the property involved, is situated at Canyon station in the Black canyon on the Phoenix-Flagstaff road, about 45 miles north of Phoenix. It has been controlled by Mr. Tribolet for the past seven years, in which time some \$75,000 has been expended in exploration and development work. There is a 350-ft. shaft and about 500 ft. of drifts. On the 350-ft. level the vein, which is narrow on the surface, has widened to 25 ft. of commercial sulphide ore. Smelter returns from 32 cars of ore shipped by the Tribolet interests show an average of 10 to 12% copper.

Phoenix, January 27.

PIMA COUNTY

(Special Correspondence.)—The exploration shaft of the Silver Queen group of mines, recently leased from William J. Bryan Jr., has penetrated an orebody on the 100-ft. level reported to assay 700 oz. silver per ton and 20% copper. The shaft will be continued to the 200-ft. level and drifts will be run at the 100-ft. level. H. S. Emlaw is supervising the work while William J. Bryan Jr. is in actual charge of the property.

Tucson, January 25.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—The South Eureka Mining Co. will discontinue operations at both the South Eureka and Oneida mines during the present week, as a result of lack of ore in paying quantities and the unwillingness of stockholders to spend more money in prospecting for better ore to mix with the large reserve of low-grade material in sight. Under the terms of the pumping agreement existing between the South Eureka Mining Co. and the Central Eureka Mining Co., the latter will doubtless be called upon to shoulder the expense of keeping the two mines unwatered. The two shafts are connected by means of long drifts and the one pumping system in

the South Eureka shaft handles the water from the Central Eureka as well as the South Eureka mine. The Central Eureka Mining Co. has paid its proportion of expense in operating this system since it was started and, for the protection of its property, may now have to shoulder the entire expense. This increase in operating expense at the Central Eureka mine, which is being operated on an assessment basis, is discouraging at this time, but recent improvement in the grade of the ore mined may enable the company to meet the demand. The plant is in better shape than for many years and 30 stamps of the 40-stamp mill are dropping steadily on ore that practically meets present expenses.—Since completing the enlarging of the Old Eureka shaft from the 1600 to the 2165-ft. point, sinking has been steadily in progress, an average of 17 to 20 ft. being made each week. The intention is to extend the shaft 1000 ft. below its former bottom before beginning extensive horizontal development.

Sutter Creek, January 28.

The Kennedy copper mine in the Buckskin mountains near Yerington is rapidly developing large orebodies averaging 3% copper and \$6 to \$8 in gold. The company is now driving under the hill at a depth of about 250 ft. and has an ore-shoot open for a distance of 400 ft., with the end not yet in sight. This is at a point 300 ft. west of the shaft, and the ore found is all of a milling grade averaging \$18 to \$20 per ton. Over 40,000 tons of this mineral is now blocked out and it is probable that with the advent of spring the company will turn its attention to the erection of a flotation plant.

ELDORADO COUNTY

(Special Correspondence.)—Active development work is in progress on the Red Wing quartz mine, situated half a mile south-west of the Martinez Gold mine and three miles south of El Dorado railroad station. The vein has been uncovered at the 200-ft. level by a 300-ft. cross-cut. Several strata of genuine 'Mother Lode' quartz have been cut, from 3 to 14 inches wide, which assay \$15 in gold per ton. The adit is being extended across the vein to the foot-wall. After the foot-wall is reached, drifts will be extended north and south and a winze sunk on the vein. Seth G. Beach and his son Joe, of Placerville, have recently acquired a large interest in the Red Wing mine.—A recent clean-up of the first mill-run of the wide friable porphyry-ore dike on the Cincinnati mine, eleven miles north-west of Placerville, yielded an average of \$3.82 gold per ton on the plates. The amount and assay of the concentrate have not been determined. The total cost of mining and milling the ore was less than one dollar per ton. The California Porphyry Gold Dike property, an east extension of the Cincinnati dike, will, it is understood, soon be developed on a large scale by New York capital.—The Aluminum Gold quartz mine, three miles south of Placerville, is being operated under a working-lease by Andrew Anderson. The Aluminum mine has a true fissure-vein of high-grade quartz, from which considerable gold has been recovered in the past.

Placerville, February 1.

NEVADA COUNTY

(Special Correspondence.)—The Grass Valley Consolidated Co. has re-organized the staff of the Allison Ranch mine.

William Harvey is superintendent; Frank R. Hull, assistant superintendent; and E. C. Uren, consulting engineer. Mr. Hull was formerly assistant superintendent of the Empire mine, and Mr. Uren for many years has been a prominent engineer of this field. It is officially announced that ore of milling grade is being mined on the second, third, and sixth levels, and that the new vein is developing splendidly. Lessees are active at a number of points and several have engaged additional miners to expedite work. Some of the lessees are reported to be averaging \$25 to \$45 per day net. Unwatering of the shaft below the 700-ft. level is making good progress.—The North Star Mines Co. is completing a restraining dam to prevent flow of mill-tailing into Wolf creek. The Golden Center, Allison Ranch, and other companies are also arranging to prevent discharge of debris into the creek. For 65 years debris has been discharged by local companies into the stream, which drains into the Sacramento river, but an order was recently issued by the California Debris Commission prohibiting the practice. —A heavy output of chrome is being made from properties at Lime Kiln. Eight motor-trucks are engaged in transporting the ore to the Oustomah mill at Nevada City, and the resultant concentrate is shipped to Eastern steel mills. The deposits are proving extensive, with much of the ore high-grade. Prospecting for chrome is active along Deer creek and promising deposits have been uncovered.—Favorable weather has enabled the Washington Asbestos Co. to work its asbestos claims, near Washington, all winter, and the mill will be placed in operation shortly. It is stated that much profitable mineral has been placed in sight in the past three months. Oakland people are principally interested.

Grass Valley, February 4.

SHASTA COUNTY

(Special Correspondence.)—The electrolytic plant at the Kennett smelters employs 75 men and is now turning out three tons of zinc per day. In addition to this 200 lb. of cadmium is recovered. Cadmium, which is worth \$165 per pound, is valuable as the base for automobile paint.

Redding, February 2.

TUOLUMNE COUNTY

The Pacific Coast Mines Corporation, controlled by W. J. Loring and powerful Eastern financiers, has acquired title to the Dutch, Sweeney, and App mines in this county, and is preparing for operations on a large scale. The mines have been undergoing extensive development for several years, and are considered among the best gold properties on the Mother Lode. High-grade milling ore was opened last summer in the new deep levels of the Dutch shaft, and effective methods for treating the sulphide ore has been discovered. The present plans include the erection of a mill of 700 or 800 tons daily capacity, with a probability that flotation will be used extensively.—The Pacific Gold Dredging Co. has established an excellent camp near Auburn, and is rapidly re-constructing the steel dredge that was formerly operated on the middle fork of the American river. An extensive area of dredging ground has been established on the north fork of the river, where the boat will operate in future.

COLORADO

BOULDER COUNTY

The Degge-Clark Tungsten Mining, Milling & Refining Co. has been re-organized and has changed its name to the Caribou Metal Co. The new company will have a capital of \$2,000,000. The Caribou silver mines have been acquired, together with several adjacent mines, and hoisting and compressor plants have been ordered. During the 'seventies and early 'eighties these mines produced several million ounces of silver, and on the dumps and in the stopes are large quantities of ore that was considered to be waste at that time.

LAKE COUNTY

A body of manganiferous iron ore, carrying 44 oz. silver per ton, has been struck at a depth of 87 ft. in a shaft at the Dunkin property on Fryer hill. A steam-boist has been placed at the shaft and the sinking will be continued until the body of ore is penetrated when levels will be driven. The shaft has already passed through 12 ft. of ore.

TELLER COUNTY

(Special Correspondence.)—The Roosevelt tunnel of the Cripple Creek Deep Drainage & Tunnel Co., during the past week, entered the Portland Gold Mining Co.'s Colorado City lode-mining claim on the north-eastern slope of Battle mountain, and its course has now been diverted south-east to a point directly under the Portland No. 2, or main shaft. At this point the tunnel will have a depth of 2130 ft.; the station to be cut there will have an elevation of 8114 ft. above sea-level and will be 26,000 ft. from the portal. While still in Rose Nicol territory, a station was made where the tunnel crosscuts the Hidden Treasure vein of the Portland system. At this point the ore ranged from \$3 to \$16 per ton. The Camp Bird Mining, Leasing & Power Co., holding a six-year lease on the properties of the Rose Nicol Gold Mining Co., will start driving from the adit-level on this vein.—Lee Martin, lessee on the Kitty M., one of the Gold Hill properties of the Mary McKinney Mining Co., has opened up a five-foot vein of milling-grade ore and has commenced shipping.—The Granite Gold Mining Co. on Battle mountain and lessees are shipping heavily and the January production will be close to 3000 tons. The value will hold to an average of \$20 per ton.—J. C. Ferrill, assessor of this county, and chairman of the Mines and Mineral Lands Committee of the Colorado County Assessors Association, has advocated a valuation on non-producing mining claims, lode or placer, of a sum not to exceed \$60 per acre. The matter was under consideration at the recent meeting of the State assessors and the valuation will be recommended.

Cripple Creek, January 31.

MONTANA

SILVER BOW COUNTY

Concreting of the Granite Mountain shaft of the North Butte Mining Co. has been completed and the cages are in operation to its lowest level. Power cables are being lowered, bells connected, and the finishing touches given to the repairing of the shaft, which was put out of commission by fire last June. The four-compartment shaft has been lined with steel beams, buried in heavily reinforced concrete down to the 3000-ft. level, below which the shaft is wet and therefore considered fireproof. With the Granite shaft in commission again, it is expected that the North Butte will soon regain its normal ore production of 1700 tons daily. The company has been lifting around 600 tons daily through the Speculator shaft for the past month.

NEVADA

CLARK COUNTY

(Special Correspondence.)—The Yellow Pine Mining Co. has arranged to use a Herman ball-mill for grinding of the middling from the concentrators; the re-ground product will be re-treated on another set of tables to effect a closer extraction. Additional rolls have been placed in commission and a new Fairbanks-Morse gas engine has been purchased. On the north end of the 700-ft. level the main orebody continues to develop splendidly; it was opened by a cross-cut 1100 ft. long. Another cross-cut has been advanced 950 ft. from the 900-ft. level and is expected to tap the vein in about 200 ft. Promising veins are also receiving attention on the 300 and 600-ft. levels in the south end of the property. The ore contains lead and zinc.—George Roth and associates have taken leases on the Mountain Boy and Mountain Girl claims of the Christmas Consolidated.

—The Hoodoo mine has been leased to D. T. Duncan and Frank Williams for five years by the Kansas-Nebraska Mining Co. Some good ore was recently uncovered, and the new operators are arranging for deeper development.—High-grade zinc and lead ore is being shipped from the Milford group, operated by the Goodsprings Mining Co. The group includes the Milford and Addison claims, near State Line Pass, on the California-Nevada boundary line. The company was formed by Jesse Knight and C. L. Hyde in 1910. E. J. Delano is superintendent.

Goodsprings, February 2.

HUMBOLDT COUNTY

(Special Correspondence).—The National Mines Co. is preparing for resumption of extensive work at its holdings in the National district. The lease held by the National Leasing Co., headed by George Graham Rice, has been canceled, following the failure of the leasing company to pay its rental for January, amounting to \$2400.—The National Nevada Mining Co. has resumed driving of the lower adit with the view to cutting the orebody exposed in the upper level. N. P. R. Hatch is manager.

Winnemucca, February 2.

MINERAL COUNTY

(Special Correspondence).—Harry B. Lind, controlling owner, has resumed operations on the Iroquois Copper on company account. The mine has been working steadily but for several months the activity was confined to lessees, who have been shipping an excellent grade of ore. The main adit on the Mastodon is being put in order, but Mr. Lind has not decided whether to continue it ahead or to put up a raise from its face to open up the orebodies which were 'glory-holed' near the surface. It is the intention to throw open a greater portion of the Iroquois ground to lessees, as Mr. Lind estimates that, without interfering with company work, there is room for 25 sets, many of whom can begin work on a commercial grade of ore.—The north-west drift on the Calavada is entering a promising country on a contact between black lime and monzonite. Between these is an oxidized vein, two feet wide, carrying considerable red oxide of copper, which, where it penetrates into the lime, changes to carbonate of copper. Work has been resumed on the south-east drift.

At the Copper Ridge, two miles east of the Calavada, a winze is being sunk from the 260-ft. level where the big 24-ft. vein contains an orebody 10 ft. wide which averages 10% copper and from which many large specimens of rich chalcocite and oxide ores have been taken. George Gironx is the owner.

There has been a cave-in at Stockham adit No. 2 of the Luning-Idaho company and progress has been delayed until it can be timbered. This adit is going out to tap at depth a good orebody which cropped to the surface and which was opened in No. 1 adit.

Luning, January 29.

STOREY COUNTY

Mining operations at the north end of the Comstock lode continue to give satisfactory results, with Union Con. maintaining average shipments in tonnage and grade of ore. The stopes continue to yield well on the 2400-ft. level, and some high-class ore is being taken out in the advance of the north drift from the 2500-ft. level raise. From the last record at this point the ore broken down averaged better than \$60 per ton. A feature of the week has been the shipment of six bars of bullion from the Mexican mill, the value of which was in excess of \$23,000. The Sierra Nevada has completed the work of placing air-pipe and other equipment on the 2500-ft. level to the vein exposed in the north-east drift from the east cross-cut, and work in the vein will be started at once. Elsewhere in the north end, conditions remain favorable; the Ophir com-

pany is shipping ore extracted from the 2100-ft. level to the Mexican mill. The ore from this level last week averaged \$18 per ton for 147 cars. The Montana company is driving ahead its exploration work as usual and the Con. Virginia continues development work on the 2700-ft. level.

The Jacket Con. is taking out much ore from the adit-level workings in Gold hill, and is operating part of its mill. Work also continues on the new equipment. Three bars of bullion were shipped last week.

It is understood that the Christmas Mining Co. has granted a lease covering all its holdings in the Gold Hill district to local parties and that operations are to be started on an extensive scale before March 1. The holdings of the company are classed as among the most promising in the district, as there are extensive surface showings of high-grade ore, while a shoot of silver-lead ore opened in the deepest shaft has been productive of ore carrying up to 360 oz. silver per ton. The holdings of the company consist of twelve patented claims, covering 246 acres, the last patents having been received May 1, 1913. The property is situated about three miles due east from Gold Hill and only two and one-half miles from the Deep Creek railroad, forming a solid group of rectangular shape approximately 7200 ft. long and 1800 ft. wide. While no special effort is being made by the Woodman Mining Co. to develop the tungsten deposits of the Frankie mine, the production of scheelite ore is being continued and several tons of high-grade ore have been accumulated. Some of the ore is extracted in chunks of good size which do not contain much waste, though, because of the tendency of the ore to pulverize easily, a good deal of the fine cannot be saved, but goes into the bins with copper ore.

WHITE PINE COUNTY

J. H. Goodman of McGill last week brought 450 lb. of ore from a recent strike made in the property of the Willow Creek Gold Mining Co., which was worth several dollars per pound in gold. The ore was shipped to San Francisco by express, Mr. Goodman placing a value on the shipment of \$2500. The new strike was made on the 160-ft. adit-level, the pay-streak being four feet wide, about eight inches of which is exceedingly rich in gold. Assays from the remainder of the vein run from \$600 to \$800 per ton. When Mr. Goodman left the mines last week the vein had been driven on for a distance of seven feet, the grade of the ore holding good for that distance, but of course the development was not sufficient to guarantee permanency.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The Mogollon Mines Co. produced 11,000 oz. gold and silver for the first half of January

MAP SHOWING SITUATION OF MOGOLLON

besides concentrate; 150 tons of ore is being put through the mill daily.—The Oaks Co. has commenced work on its Cen-

tral shaft. Two shifts are at work. Development and production continues from Maud S., Deep Down, Clifton, Eberle, and Pacific mines, which are being operated by this company. —The Socorro Mining & Milling Co. is making good headway with its new mill. An effort is being made to have the mill in operation by May 1. Development is being continued underground and the broken ore-reserve is being increased. Hoisting will be started as soon as the head-frame is complete. —The district is again abundantly supplied with water after a long dry spell.

Mogollon, February 2.

OKLAHOMA

OTTAWA COUNTY

The Federal Lead & Zinc Co., owning leases in the North Century field, has just closed a contract for the erection of one modern 300-ton plant on one of its tracts. Two leases, one of 20 acres and the other 40, have been thoroughly developed, with some of the drill-cuttings reported to have shown as high as 50% ore. The mill, for which a contract has just been let, is to be erected on a blocked-out site on the 20-acre lease. Steam will be used for power in the first plant, according to the plans and details. Three 150-hp. high-pressure boilers have been ordered. A 150-hp. Corliss engine will be used. Henry M. Martin of Miami has been awarded the contract to build the mill. The plans and specifications show that it will cost around \$85,000. Hubert L. Bolen is president; J. P. Whatley, vice-president; Verne Thompson, secretary and manager; and A. M. Brannon, treasurer. —An excellent deposit of ore has been developed on a lease of the Southeastern Missouri Mining Co., situated between Picher, Oklahoma, and Treece, Kansas. Of the 31 completed holes on the tract a majority of them have shown ore at almost a uniform depth. The company has 40 acres in all, with a shaft already started and plans completed to erect a mill of 500 or 600 tons capacity.

OREGON

JACKSON COUNTY

(Special Correspondence.)—The Gold Hill Manganese Co. has been incorporated with a capital of \$1,000,000 and headquarters at Grants Pass. The property is known as the Manganese Consolidated, was located in 1909, and recently sold by McCallister & Britten to L. F. McConiche of Tacoma. It consists of four claims on Shan creek, six miles from Rogue river. Recent assays show 24 to 44% manganese, with gold-bearing quartz running as high as \$724 per ton. The mine will be equipped with jigs, water motor, crushers, rolls, sawmill, and stamp-mill, and \$5000 will be spent on the road leading to the mine.

Gold Hill, January 30.

(Special Correspondence.)—Allen Davis and W. A. Patrick, of Ashland, are developing a chrome deposit 10 miles west of that city. Talent is the nearest shipping point with a down-grade haul. —Croppings of asphaltum and dried oil, which can be traced for half a mile, have been uncovered on government land six miles east of Ashland. M. G. Womack of Medford, associated with men of that city, and H. J. Barton, of California, have located claims on the deposits. The ground will be explored at once to determine the advisability of exploiting for oil by drilling.

Gold, Hill, January 31.

CANADA

BRITISH COLUMBIA

Nickeliferous pyrrhotite has been discovered at Barkly sound, Vancouver island, by A. L. Smith, of Alberni. Samples assayed at the provincial assay office at Victoria averaged 1.5% nickel, while those sent to the laboratory of the Department of Mines at Ottawa assayed 2.5% nickel.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

CHARLES JAXIN is in New York.

W. J. HAMILTON has gone to Peru.

ALBERT BURCH has gone to Washington.

S. HERBERT WILLIAMS is here from Ely.

F. E. GRAHAM BERRY has returned to Seattle from Amador, California.

O. D. WELSCH has gone to Tonopah after a short visit in San Francisco.

O. B. PERRY has been promoted to Lieutenant-Colonel in the Engineer Corps.

J. POWER HUTCHINS is now in New York, his office being at 120 Broadway.

JAMES P. GASKILL has opened an office in the Security building at Los Angeles.

JRA B. JORALEMON is Captain in the Signal Corps of the U. S. Army in France.

MORTON WEBBER was in New York on a hurried visit and left again for the West.

CARLOS W. VAN LAW has left Boston on a trip westward, including British Columbia.

A. N. TALBOT has been elected president of the American Society of Civil Engineers.

HUGH R. VAN WAGENEN, now resident at Pioche, Nevada, has been in San Francisco.

SPENCER BISHOP has been appointed chief mechanical engineer to the Arizona Copper Co. at Clifton.

WHEELER O. NORTH has been appointed assistant to the general superintendent of the United Great Eastern Mining Co., at Oatman, Arizona.

A. H. HIGGINS, a distinguished member of the Minerals Separation staff, has arrived in San Francisco to prepare for the bearing of the Butte & Superior case.

J. PARKE CHANNING has taken over the duties, as consulting engineer to the Utah Consolidated Mining Co., of his brother R. H. CHANNING, who has volunteered for military service.

THE INCOME TAX AND OTHER FEDERAL TAXES. By Joseph J. Scott. 300 pp., with appendix 50 pp. and index 20 pp. San Francisco, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.

Joseph J. Scott was formerly Collector of Internal Revenue at San Francisco, and his book contains instructions in the simplest and plainest language to determine the exacting requirements of the present United States tax laws. The technicalities of legal language have been discarded and in plain words the taxpayer is told precisely what he can do and what he must do. The farmer's problems are treated in detail so that every farmer can tell what to do. In the past the farmer, as a rule, has experienced a great deal of difficulty in complying with the income tax law. Under the new laws his difficulties are multiplied. Practically every farmer, merchant, tradesman, professional man, and salaried man, and a great many wage-earners, will be required to make reports and to pay tax. It will be necessary for the taxpayer to be correctly informed as to his rights before he is called upon by the Government officer to make his report. He must know how to claim all his allowable deductions; otherwise, he may overpay his tax hundreds of dollars. With the exemption lowered to \$1000 in the case of single persons and \$2000 for married persons, thousands who have never paid income tax must do so this year. This book answers the questions that arise under the income or excess profits tax-laws.

THE METAL MARKET

METAL PRICES

San Francisco, February 5

Aluminum-dust (100-lb. lots), per pound.....	\$1 00
Aluminum-dust (ton lots), per pound.....	\$0 95
Antimony, cents per pound.....	16 00
Antimony (wholesale), cents per pound.....	14 25
Electrolytic copper, cents per pound, in carload lots.....	23 50
Electrolytic copper, cents per pound, in small quantities.....	24 07 1/2
Pig-lead, cents per pound.....	8 00
Platinum, soft and hard metal, respectively, per ounce.....	108—116
Quicksilver, per flask of 75 lb.....	\$125
Spelter, cents per pound.....	10 00
Zinc-dust, cents per pound.....	20 00

A tentative price of \$90 per oz. has been set by the Government for the purchase of 21,000 oz. of platinum recently imported from Russia. Bankers in Petrograd who financed the collection of the metal will be allowed to produce proof of the expense incurred if they think a higher payment should be made.

ORE PRICES

San Francisco, February 5

Antimony, 35% metal, per unit.....	\$1 00
Chrome, 34 to 40%, free SiO ₂ , limit 8%, f.o.b. California, per unit, according to grade.....	\$0 60—0 70
Chrome, 40% and over.....	\$0 70—0 85
Manganese, crude, per ton.....	\$8 00—10 00
There is little demand for either calcined or crude manganese.	
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mo quoted on the basis of 48% material.	
Tungsten, 60% WO ₃ , per unit.....	26 00
Tungsten ore remains firm.	
Molybdenite, per unit MoS ₂	\$4 00—15 00

EASTERN METAL MARKET

(By wire from New York)

February 5—Copper is quiet and unchanged at 23.50c. all week. Lead is inactive and firm at 7c. all week. Zinc is dull and unchanged at 7.87c. all week. Platinum is unchanged at \$108 for soft metal and \$116 for hard.

SILVER

May 1917.....	76.44

Samuel Montagu & Co. says: A feature of the general monetary situation in Hongkong and South China is the extraordinary exchange value of gold, which has resulted from the prohibition of exports of the metal from various warring nations, and particularly from the United States and Japan. Current exchange-bureau rates in Hongkong today are \$3 in American paper for \$4 American gold coin—a premium of 25% for the metal over its equivalent in a monetary medium that is equally current at par in the United States or over corresponding bank exchange. There is a fair demand for silver for the purposes of trade, fortunately sufficient supplies have been forthcoming for the last few days without the price being affected. The Shanghai exchange has been firm at the official quotation of 45 sd per tael.

COPPER

ORES

Molybdenum and antimony. There is no change in the range of quotations for molybdenite, which is \$2.15 to \$2.20 per lb. of MoS₂ in 100% material. Canadian concentrates are being offered more freely. The antimony ore market is inactive in New York.

Manganese ore: Quotations for both foreign and domestic high-grade ore range from \$1 to \$1.30 per unit. The Brazilian government has declined to bring any more ore down from the mines on its Central Railway because of lack of coal, and manufacturers in this country have been notified to send no ships to bring ore already contracted for. Sixty days is reported as the time set for the idleness of the road.

Ferro-chrome: Offers have been made in this market at 35c per lb. for contained chromium for certain grades.

Charles Hardy says: A fair business has been done during the past week in tungsten ore, especially in wolframite, and prices ranging from \$36 for the highest grade to \$20 for off grade ore have been realized. The business, however, is much handicapped by railroad embargoes, not only here for shipments West but also from the West Coast for shipment East, and it has been practically impossible to sell any Californian scheelite for this reason, as buyers do not know when purchases now made will be likely to reach the East. Nominally scheelite is held by the largest producer at \$30 per unit, but business in spot lots has been done at a heavy discount.

Chrome continues scarce and people are asking as high as \$1.75 per unit for 45 to 47% material landed New York. Sales have been reported made at \$1.55 per unit, but none have been confirmed at the higher figure.

Eastern Metal Market

New York, January 31.

Monday was fuelless, workless, and lightless day in this town, and practically no business in metals was done. The market has been mostly quiet the past week except in copper.

Copper has been quite active at the Government prices.

Spot tin is as scarce as ever at nominal prices.

Lead is very dull, but decidedly firm.

Zinc is very quiet at unchanged levels.

Antimony is lifeless at the same prices as a week ago.

Snow, cold, and floods, alternately have continued to interfere with steel and pig-iron output east of the Mississippi. Chicago is but slowly recovering from almost a complete shutdown. War shipments constitute about 75% of the current movement in the heavier finished steel lines. The supply of low-phosphorous pig-iron is not regarded as sufficient to make enough acid steel for gun-forgings required by the Government. The announcement that Brazil has practically shut off manganese-ore supplies for 60 days is a source of considerable comment now and some anxiety. The refusal is due to lack of coal to operate railroads in that country. This, coupled with the facts that our imports of ferro-manganese and the domestic output have declined decidedly recently, is not reassuring.

COPPER

Producers have been selling copper freely at the Government price of 23.50c, since the announcement, noted in our letter last week, that the price would remain in force until June 1. This decision steadied the entire market. The sales made have been for delivery until that date, and have included all consumers, both the Government and individuals, with the usual restrictions, as a matter of course. There is not much spot copper available, due largely to the fact that arrivals of ore at the refineries, most of which are in the East, have been delayed because of the railroad congestion. The belief continues, however, that the supply will be ample for the coming months. The movement into consumption is known to be enormous. This adjective also applies to the exports, which have been on an exceedingly large scale. Estimating the December outgo at 35,000 tons, the total for 1917 will be 484,123, as compared with 327,310 tons in 1916, with 276,344 tons in 1915, with 360,229 tons in 1914, and with 332,810 tons in 1913, which was the banner year before the War. Imports have been large. For 1917 the estimate is 239,000 tons, against 199,000 tons in 1916, and 137,500 tons in 1915.

TIN

The feature of the week was the commandeering for the second time by the Government of tin in storage warehouses. This took place on January 23, and was for the needs of the Army, the previous occurrence, some weeks ago, having been for the Navy. Some surprise is expressed that this should be possible without the knowledge, or at least without the instrumentality, of the Tin Committee of the American Iron and Steel Institute. It is understood that some of the tin, seized in that manner last week, has been released to the regular consumers to whom it belonged. Importers are having a world of trouble, and the complaint is general that there is no pleasure in doing business. The tin situation in New York is really bad. If a dealer or importer is able to get it across the ocean and into port he encounters difficulty at once in shipping it to the interior because of railroad embargoes. If he leaves it on the dock beyond a prescribed time, the steamship company consigns it to a storage warehouse. If the metal is brought overland, there loom up losses due to demurrage

and to railroad delays. If the metal finds a lodging in warehouses, it is commandeered by the Government, and so it goes. The importer is 'getting it' from all directions and consumers are clamoring for tin that they urgently need. Quiet pervades the market in general. Spot tin is unobtainable, but is nominal at 85 to 86c. per lb., New York, with sales reported of small lots of a ton or so at 90c. to \$1 per lb. There has been a little business in futures, but the demand has not been widespread. Last Saturday a little business was done in far-off future tin, very quietly put through. Yesterday, sales of March-April shipment from the East were reported. Arrivals up to yesterday inclusive were 1720 tons, with 5300 tons reported afloat. The London market is lower. Spot Straits yesterday was quoted at £299 10s. per ton, as compared with £302 a week ago.

LEAD

Quotations are unchanged from last week at 6.85c., St. Louis, or 7c., New York, in the outside market, with the American Smelting & Refining Co. asking 6.75c., New York. The market is still at a dead stop, with transportation the controlling factor. Arrivals from the West are much delayed. There is plenty of metal in cars, but at refineries, and in the markets, it is getting scarce. The leading producer is reported as taking no February business, but as accepting March orders at its quotation. Spot lead is higher, according to reports to the effect that spot metal has sold in the last few days at 7.37½c., New York, with retail lots at 7.75 cents.

ZINC

Considerable has been heard lately about a 40% contraction in the zinc output of the country. This is probably true, but the effect is now being offset or neutralized by a decided lessening in exports, leaving more metal available for the market. While the export demand is still large, facilities to ship it are contracting because vessels are being urgently pressed into other service. The market continues dull and uninteresting, with demand at a low ebb. Business continues of the small-lot order at the levels which have prevailed now for nearly two months, or 7.62½ to 7.75c., St. Louis, or 7.87½ to 8c., New York, for prime Western for early delivery. Spot metal has sold at 8c., New York, recently. The market does not go up because of lack of demand, and it cannot go much if any lower because it is regarded as now at rock bottom. Evidence of this is contained in the fact that representatives of Western mining interests recently met in Washington and notified the Government that there was no profit in their business with zinc at less than 10c. per lb. They are reported to have asked for a fixed price at this level.

ANTIMONY

There has been no change in the last week. Quiet pervades the market, which is quoted at 14c. to 14.25c. per lb., New York, duty paid, for Chinese and Japanese grades for spot and early delivery.

ALUMINUM

The market is without life for spot and early delivery and is quoted at 36 to 38c. per lb., New York, for No. 1 virgin metal, 98 to 99% pure.

ORES

Tungsten: The market is quiet at the regular quotation of \$24 to \$26 per unit in 60% concentrate, with scheelite commanding the higher price. Transactions are reported in moderate volume. Ferro-tungsten is unchanged at \$2.35 per lb. of contained tungsten.

SHORT courses of instruction to prospectors are given in the Mackay School of Mines at Reno, Nevada. We note that a class of 17 was in attendance through the four weeks in January during which this special instruction was forthcoming. Most of these adult students come from Reno, but occasionally prospectors from far afield join the class. This departure in the teaching of the art of mining is well worthy of commendation.

OUR friends at Butte appear to have had an excellent annual meeting of their section of the Institute on February 1. We have read abstracts of some of the papers presented on that occasion as published in the 'Butte Miner' and congratulate the members in Montana on being able to organize such an interesting technical session. The papers by Mr. F. W. Baeon on shaft-sinking, by Mr. C. H. Clapp on contact deposits in British Columbia and Arizona, and by Mr. C. D. Demond on hydraulic classification should prove notable contributions to the Transactions.

NEUTRAL testimony in mining lawsuits has been recommended often as a means of escaping from the distortions of hired advocacy. It is interesting therefore to note that the experiment was made in the recent trial of the White Caps v. Morning Glory case, before Judge Mark R. Averill at Tonopah. Two geologists, Messrs. Hugh R. Van Wagenen and R. T. Walker, were chosen by agreement between the litigants, and at their expense, to advise the Court. It so happens that the testimony of these advisors favored one side so strongly as to seem partisan to that side, but we hope that the precedent may be followed by other courts, so that the day may come when expert testimony will be predominantly at the service of the Court instead of being in the hire of the litigants.

HEARST and his string of yellow journals have made a characteristic use of the 'Tuscania' disaster. In the first place he employed it hysterically as a stimulant to patriotism, although he had found excuses for the sinking of the 'Lusitania.' One ship was the victim of an act of war whereby we lost 113 soldiers on their way to fight the Germans; the other was the victim of piracy whereby 122 innocent American passengers were assassinated while being ferried across the Atlantic. Not content with a distortion of fact, he suggests that the 'Tuscania' disaster was due to British incompetence, just because his lying news-agency was suppressed by the British government. Of the 210 that were lost, 97 belonged to the British crew. Acts speak louder than words. To the common sorrow and the common resentment of Americans and Englishmen caused by the 'Tuscania' disaster we may add the common contempt for prostituted journalism.

Not content with a distortion of fact, he suggests that the 'Tuscania' disaster was due to British incompetence, just because his lying news-agency was suppressed by the British government. Of the 210 that were lost, 97 belonged to the British crew. Acts speak louder than words. To the common sorrow and the common resentment of Americans and Englishmen caused by the 'Tuscania' disaster we may add the common contempt for prostituted journalism.

ONE of the splendid assets of the Pacific Coast is its water-power. The possibilities are infinitely greater than the present development. California alone has a potential 6,593,000 horse-power in its streams, of which only about 600,000 horse-power is now available at the switch-board. Mr. M. O. Leighton estimated several years ago that the Pacific Coast States as a whole offered a minimum of 16,195,000 horse-power awaiting the call for industrial utilization. Having these facts in mind, Mr. Joseph W. Richards stated the other day that "electrochemical and electro-metallurgical industries are undoubtedly going to develop very fast on the Pacific Coast. There will be some set-backs, of course, due to carelessness or over-enthusiasm, but it is perfectly clear that development will take place in the same direction as in Sweden and Norway, and that a new industrial era is beginning to dawn on the Pacific Coast."

FRRIENDLY co-operation, to an unusual degree, appears to mark the relations between metallurgists in Mexico at this time. We are informed that the members of the technical staffs of companies operating at Pachuca have been most generous in their exchange of information concerning practice with their professional comrades at El Oro. It may be that the enmities so rampant in the world generally, and in Mexico particularly, have prompted a growth of friendly feeling between men engaged in similarly useful work, or it may be that the isolation of life in a sea of political trouble may have drawn them together in the furtherance of a common purpose, or it may be that they are just gentlemen and scholars; whatever the cause, we record the fact with keen pleasure. The man that plays a lone hand plays a poor game; co-operation is a characteristic of

civilization. Apropos of such a manifestation of good sense, we venture to refer to the letter from Mr. F. C. Brown in our last issue. Mr. Brown, as our readers are aware, is the inventor of the agitator that is known as the Pachuca tank. Instead of 'holding up' operators at the point of his patent he appealed to their sense of fairness, asking them to pay him a reasonable fee for the use of his invention, in proportion to the number of his machines that they used. As he records, the response was generally favorable, and he found himself adequately compensated without going to law or using threats of any kind; in short, he was paid for engineering service.

A DISTINGUISHED mining engineer, recently returned from Washington, has expressed to us his belated appreciation of the good work that is being done by the American Mining Congress, as represented by Mr. J. F. Callbreath, the secretary of that organization. Like many others our friend had been under the impression, which we shared at one time, that the Mining Congress was kept going by a group of second-rate promoters and men of that ilk, although from time to time sundry professional men of high character had associated themselves temporarily with the organization. The point of this story is that the mining engineer whom we have quoted has confessed to us his discovery that Mr. Callbreath and Mr. Walter Douglas, the distinguished president of the Mining Congress, are doing a distinct public service at Washington and are performing a function necessary to the protection of the national mining industry. They need support, in the form of more extensive membership, to be secured by the formation of local State chapters. To put his opinion into effect our informant himself became a member and is now taking steps to further the second suggestion. We share his view-point. The American Mining Congress has had its vicissitudes; it was not always an agency that the mining profession could support with real enthusiasm. For ourselves, we began to take it seriously when Mr. J. H. Richards was president for several years and was supported by such men as the late Ernest R. Buckley, trying not in vain to make it a useful factor. To the Mining Congress we owe the creation of the U. S. Bureau of Mines, the Safety First propaganda, and the efforts to amend the mining law. We need an organization that will include all the diverse elements engaged in mining and we need some sort of annual convention in which these elements can be articulate. We need also somebody authorized to watch legislation in Congress in behalf of the mining industry, somebody or some committee that is out of politics and free to act independently in the interest of mining. Mr. Callbreath should be given the goodwill and support of the mining fraternity, and to that end it will be well if the California Metal Producers Association, having its headquarters here in San Francisco, and the Chamber of Mines and Oil, at Los Angeles, would join in forming a Californian chapter of the American Mining Congress.

The Railroad Problem

Agitation over the transportation problem continues; the order for fuelless Mondays is being enforced rigidly; yet the railroads are but slowly overcoming the congestion of freight that was bringing the system to the verge of paralysis. Accusations have been made by Mr. W. G. Lee of the Brotherhood of Trainmen that the high officials of the transportation systems are seeking deliberately to provoke failure in the Government management, and a wordy battle has arisen. Meanwhile evidence of active influence by railroad officials is apparent in Congress, where bills have been introduced having the purpose of compelling the return of the roads to their former managers after the War. This contest is of considerable interest to the mining world; in the past it has suffered from discriminations that even the interstate commerce laws did not succeed in curing. It is immaterial who controls the railroads if fair dealing is joined with good management. The large mining and smelting companies usually are under no great difficulty in obtaining favorable treatment, but the small operator everywhere tells a different story, and even powerful concerns, such as the Bunker Hill & Sullivan company, have had to struggle against discriminative freight-charges. The Graselli company enjoyed rates for zinc concentrate to its plant at Clarksburg, West Virginia, in combination with rates on the spelter from this point to New York that could not be duplicated in favor of Chesapeake tide-water points without prolonged and costly hearings, involving delays in themselves calculated to restrain the growth of competition. These are merely recent examples out of many. There is no discrimination in the Post-Office; it is a transportation business conducted on a vast scale, efficiently, economically, and democratically. The people would like to see the railroads operated on a similar democratic basis. It is interesting to note that the opposition to Government control is not being made by the owners of the railroads, but by the high-salaried officials. The National Association of Owners of Railroad Securities has published figures showing that one million individuals own 10 billion dollars worth of railroad stocks and bonds, that life-insurance companies representing 46 million individuals hold one and a half billion dollars, and that savings-banks representing 10 million depositors hold nearly nine hundred billion dollars; in fact, over 14 billions out of a total of 17 billion dollars worth of railroad securities is held by the general public in relatively small lots. As an example of the distribution of ownership the register of the New York, New Haven & Hartford, which is typical, reveals that the stock is distributed among 25,769 individuals, half of whom are women, and 11,915 hold less than 10 shares each, while owners of more than 500 shares each number only 367. Another interesting fact in relation to the American railroads, which makes them the people's enterprise in a more amplified sense, is that they were largely built by popu-

lar flotations of stock, and then, in the subsequent juggling of financiers for control, in errors of judgment, in mistakes of management, and in their exposure as private corporations to the demoralization of financial crises, almost the whole of them have passed through bankruptcy and re-organization, so that the men and women whose money originally built them were squeezed out. Surely the people of America have subscribed handsomely for the sake of providing arteries of commerce. Neither do the securities present and past measure the investment. Few towns have escaped assessment to purchase right-of-way and yardage to present to some railroad as an inducement not to build past it and create a rival municipality. Even bonuses in cash have been paid for such favors. Interference by the railroad managers with the successful operation of the system would be a wrong to the community, and they do right to demand proofs from Mr. Lee that he has not accused them without cause. Meanwhile, it would do much to inspire public confidence in their sincerity if the trail of their activities were not so conspicuous in Congress through bills evidently drafted to defeat the plans that the Administration had considered important in connection with its emergency effort to operate the nationalized transportation system for the welfare and safety of the nation.

Monetary Use of Silver

Silver to the amount of \$490,000,000 has been coined, and against the metal held in the Treasury, \$468,000,000 in silver certificates has been issued. It is now proposed to melt 150,000,000 of these silver dollars in order to provide additional bullion for export. At the same time purchases of silver throughout the year would gradually replace these withdrawals, and the corresponding foreign credits would involve our Allies in the absorption of silver for monetary purposes without discrimination, in the export balance, in favor of either gold or silver. While not equivalent to bi-metallism, this step would, however, assure an international standing for silver that would prevent the forcing of gold to a premium, or the withdrawal of gold from this country in exchange for silver, as would happen if we should attempt bi-metallism single-handed. It would appear to be a plan for enlarging the international hard-money basis for credits without the dangerous formality of monetary treaties. It is also said that silver certificates, of the lower denominations, will be recalled and exchanged for Federal Reserve bank-notes. These are quite distinct from Federal Reserve notes, of which \$1,369,000,000 have been issued. The new notes would appear to be intended as a means of releasing more silver for export in proportion to the silver certificates they replace, since they are to be secured like National Bank notes against Government bonds. This is indirectly a further expansion of credit against the metallic basis, but it involves foreign credits on account of the export of silver bullion, and thus ac-

quires an international relationship, which would tend to stabilize the issue. Such connecting links between the currency and the obligations of one national treasury to another, in which is closely involved the credits arising from trade-balances, would soon put an end to anomalies of the kind recently reported from the Far East, where American paper money was accepted only at a 20% discount. An essential condition for a sound currency system is elasticity to meet the fluctuating needs of trade, and silver in this instance performs a useful office in rendering possible the expansion demanded by the extraordinary conditions that have arisen from the War. The governments of Great Britain and France face currency problems not unlike our own at this moment, and the simultaneous demand for an enlarged metallic basis for credits temporarily has resulted in utilizing silver again in world finance, but this is based upon the law of supply and demand, and must change with altered conditions. As a matter of fact no such thing as bi-metallism can exist. It is the exchange value of silver in terms of gold coin that rules; no one ever thought of valuing gold in terms of silver.

The Control of Flotation

The description of successful experiments in the use of plain sea-water for the flotation of copper minerals, appearing in our last issue, will have interested many of our readers. The publication of the discovery will prevent anybody from obtaining a patent, and it would establish priority of invention on the part of the writer if he had already applied for patent. Publication is not only a direct way of obtaining proper credit for metallurgical research, but it prevents the perpetration of that meanness whereby an investigator is enriched out of his idea by a patentee before he himself has brought the idea to fruition. The use of sea-water as a natural frothing-agent carries a humorous suggestion. Will the patent-exploiters that are trying to establish a monopoly of flotation succeed in claiming that this new departure is a trespass on their preserves? Can anybody claim the exclusive right to dip into the ocean or even to utilize the great lake in Utah that seems to us now to be a noble body of brackish water? We think not. If, when refining zinc by electrolysis, the ore happen to contain manganese, can the patentee of a method for using manganese, in the cycle of purification and acid-regeneration, penalize the refiner for his use of the manganese placed by nature in his ore? No, fortunately for the owners of the Sullivan mine and the Consolidated Mining & Smelting Company of Canada. It would be as futile to lay an embargo on Nature as for Mrs. Partington to expect by exercise of her broom to sweep back the oncoming tide. We shall expect to hear more about the use of sea-water, Salt Lake water, and the brine of the desert region. As was suggested last week, the employment of alkaline chlorides, notably salt, is not new in flotation. In patent No. 1,182,290, of 1916, Mr. Leslie

Bradford aims to separate galena from pyrite and blende by using acidulated alkaline chlorides. He says that the solution preferably should be feebly acidulated. In another patent, No. 1,203,372, Mr. F. J. Lyster uses alkaline chlorides, among other reagents specified, to produce a differential flotation of galena in the presence of blende. He desires much more alkalinity than belongs to sea-water, for he says that the water should always contain enough alkalinity to react well with methyl orange. The mine-water at Broken Hill proved suitable for his purpose; it contains 178 grains of chlorine per gallon as against 130 in normal sea-water. These patents of Messrs. Lyster and Bradford belong, of course, to Minerals Separation, which has acquired a vast array of claims in the expectation of controlling every phase of flotation. That expectation we hope to see frustrated.

Another possible avenue of escape from the monopoly of Minerals Separation is the patent of Mr. Walter A. Scott, described in our issue of December 22. We understand that it has been used successfully in experiments made at the Ray copper mine and elsewhere. Mr. Scott's method consists in the use of oil-vapor. Oil is neither mixed with nor added to the ore-pulp, but simply introduced in gaseous form in admixture with air. Apparently this method conforms with the requirements specified in the decision of the Court of Appeals in the Miami case. There is no agitation of the pulp, and the oil is not even added to the pulp before its introduction into the Callow cell. The Court stated: "If the only agitation to which the pulp was subjected (after such agitation as in the prior art was necessary to mix the oil and ore) was the agitation of the Callow cells, we would not say that that amounted to or was the equivalent of the violent agitation of the patent disclosure and constituted infringement." This last refers, of course, to patent 835,120. The language of the Court is not lucid, but we think the meaning is fairly evident. The agitation used at Miami was no greater than that described in many prior-art patents and publications, notably the Kirby patents and the article in the 'California Journal of Technology' by Messrs. Copeland, Butler, and Wise; still the Miami agitation was held to constitute infringement, because it involved the use of a pump and a pachua. Evidently, in order to escape infringement of No. 835,120, it is necessary to avoid any semblance of agitation in the operation of mixing the oil with the pulp. This the oil-vapor method accomplishes. Nor can Minerals Separation fall back on patent 793,808, in which bubbles of air were introduced into the pulp from a perforated coil of pipe, because the inventors, Messrs. Sulman and Picard, have themselves testified repeatedly in court that the method of this patent did not produce a persistent froth and was a failure. If these witnesses for Minerals Separation had testified that this particular patent produced either the agitation-froth effect or the Callow-cell effect they would have invalidated patent 835,120, a later patent, on which they relied to obtain a monopoly to flotation. Patent 793,808 would not suffice for their purpose

because it contains no claims that would be infringed by the milling operations of today. Hence their enthusiasm in testifying that No. 793,808 produced no persistent or coherent froth comparable with the miraculous effect of No. 835,120. An attempt to contend that 793,808 contains a description of the oil-vapor process would involve them in complications either tragic or humorous, according to the point of view. It is hardly conceivable that any court would be influenced by a belated effort to trim their sails to the breeze that now blows from an entirely different direction.

It may be interesting, however, to see in what respects patent No. 793,808 differs from that of Mr. Scott, No. 1,246,665 of November 13, 1917. The first claim of 793,808 is "bringing the pulp into intimate contact with 'oil' in the form of spray and with a gas." A spray, which we conceive to be a grosser dispersion than a mist, is a suspension of minutely divided liquid particles carried in a stream of gas having velocity sufficient to maintain the state of suspension. Nothing in the nature of a spray plays any part in the oil-vapor process, in which the modifying agent is in the form of a gas that is released in the pulp as gently as possible in order to make minute bubbles, which rise quietly through the pulp in obedience to the force of gravity. The second claim of 793,808 is limited to a procedure wherein the pulp is brought "into intimate contact with oil disseminating the mixture through air." Mr. T. J. Hoover, in British patent No. 10,929 of 1910, uses the idea of introducing gas into the pulp through a porous medium. This patent was not duplicated in the United States, and therefore is not in force in this country. Such as it is, the patent, which belongs to Minerals Separation, makes no reference to the building of a bubble-column and the removal of the bubbles from the upper part of the column simultaneously with the formation of more bubbles by the continuous introduction of air; it is based solely on the use of the idea of introducing air through a porous medium in a conventional apparatus in which the pulp is aerated and then led to a vessel wherein it is permitted to become quiescent for the formation of a froth. Schwarz in U. S. patent No. 1,237,961 and Malkemus in British patent No. 15,292 refer to processes in which they treat the pulp in vessels sealed against the atmosphere and in which they repeatedly circulate different gases or vapors through the pulp. They appear not to anticipate the oil-vapor method, the importance of which, of course, arises mainly from the fact that it does not appear to infringe the Minerals Separation basic patent, No. 835,120. As to that we shall know more when the Court of Appeals in San Francisco has given its opinion in the Butte & Superior case, which will be reviewed on March 8. Whatever the decision, we may expect an appeal, by writ of certiorari, to the Supreme Court, which will then have an opportunity to remove the obscurity clinging to its decision in the Hyde case. Meanwhile, what with sea-water and oil-vapor, there is hope of a better day for the users of the flotation process.

development and expression. The words, "Man shall not live by bread alone, but by every word that proceedeth out of the mouth of God" surely indicate that there is something else besides body and mind. Develop either of these alone and what do we have: the bestial gladiator of old, or the modern speculative philosopher, who is so wrapped up in his own wisdom that his eyes are blinded to the real things of life. Are we to follow Nietzsche and Treitschke, for example?

Even in these days a man has a soul, and the development of this, along with that of the body and mind, makes the really useful citizen. I continually meet young men, fresh from college, who argue that there is no soul, because its existence cannot be scientifically demonstrated. I simply take the stand that these men are not properly educated and they have not caught the vision that the knowledge of God is the beginning of wisdom.

Now that prohibition is going ahead by leaps and bounds, there is a chance of getting back our Sunday. If not a day of labor, it need no longer be a day of carousal and 'bust.' No, do not take away the day of rest that God has given us, but let us seek out true wisdom and shape our industrial life accordingly.

Efficiency is good, when built on a sure foundation; but it now makes one ponder when he sees that this 'efficiency,' which, during the last decade has pronounced such vast material wealth throughout the world, is now being used to destroy it.

F. C. BROWN.

Silver City, Idaho, January 11.

Silver and Bi-metallism

The Editor:

Sir—For the first time since 1893, when the British government startled the world by closing the Indian mints to the free coinage of silver, that metal is rapidly approaching in value and importance, as a basis for barter and credits, the standard maintained by it for many centuries. The causes leading to this condition have been in operation with increasing force for the past decade, and although the present situation has been greatly augmented by the world war, it would undoubtedly have been reached in the ordinary course of business before another decade had passed.

This has been brought about primarily by the increasing demand for silver for the purposes of coinage, and, secondly, by the increasing demand for silver for industrial uses. The first increased demand is due to two causes; a dearth of gold and an increase in the total volume of the world's business. From 1904 to 1916, both included, the world's production of gold increased from \$347,000,000 in the first year to only \$470,000,000 in the past year, and since 1912 the production has been practically constant. The figures for 1917 are not yet available, but the production is estimated at only \$430,00,000, the decrease being due to some extent to the curtailed production in South Africa. In the meantime, the world's volume of business has increased manifold. In-

asmuch as a large proportion of the world's business today is done on credit, and as metallic money is the final basis of all credit, it is evident that the ratio between the volume of credits and the value of the metallic basis for this credit is rapidly increasing. As there is no immediate prospect for an increase in the production of gold—in fact, since the beginning of the War the production of gold in many of the most important gold-producing centres has decreased—it is equally evident that, in order to maintain that second ratio between the metallic basis and the volume of credits, the production of silver must be enormously increased, or its value, that is, its credit-purchasing power, will increase. The first is impossible; the latter obeys the law of supply and demand.

It was estimated that, on January 1, 1917, the public indebtedness of the six leading nations at war amounted to 70 billion dollars. It is further estimated that on January 1 of this year this public indebtedness had reached the bewildering sum of 100 billion dollars. On the other hand, the estimated legal-tender value of the world's available supply of gold and silver money is approximately 10 billion dollars. In this estimate it must be noted that the legal-tender value of coined silver is \$1.2929 per ounce. In other words, at the present time each one dollar of metallic money must do ten times as much in credits, whereas the normal rate is between six and seven times. With the enormously increasing indebtedness of the nations at war, together with the further increasing volume of credits in the commercial world, combined with the practically stationary production of gold and silver, it is painfully evident that the metallic basis for all this credit has reached the limit of safety, making the re-monetization of silver at \$1.2929 per ounce imperative in the near future. So great is this need that Mr. Balfour, on his recent visit to the United States agreed, so it is understood, to an international conference of England, France, and the United States, looking toward the re-establishment of silver, that is, the restoration of the bi-metallic standard.

The enormous increase in the consumption of silver for industrial purposes is largely due to the fact that the low price of metallic silver obtaining from 1900 to 1912 was accompanied by a corresponding lower price for sterling silver articles, and that during this period general prosperity and wages constantly increased throughout this country. The result is that people and families who formerly used plate became accustomed to, and will consider nothing but, sterling silver for domestic use. It is well known that one firm recently, at a time when silver was quoted at 85 to 87c., was unable to obtain 3,000,000 oz. imperatively needed in its manufacturing business, although a price of well over \$1 per ounce was offered.

The enormous need for silver coinage, apart from that needed to pay soldiers removed from industrial occupations, is caused by the requirements both of Great Britain and the United States in settling trade balances

with the Far East, namely, India and China. Since the de-monetization of silver, England has paid her trade balances with India largely in gold. After the beginning of war, it was increasingly necessary for England to husband her gold resources. The British government prohibited the export of gold to the Far East. This was followed during 1917 by an embargo on the export of gold, except for specific purposes, on the part of the United States. It thus became necessary, in the trade with the Far East, for silver to take the place of gold in the settlement of trade balances, which, owing to the large crops in India, have yearly become heavier. In order to meet this situation during the past year, large buying orders for silver were placed in the United States; this caused the rapid rise in the months of June, July, August, and September of 1917, when, in September, a price of \$1.10 per ounce was recorded in New York. Foreign financiers, realizing that a runaway market had been created, canceled many orders, with the resultant fall in price and the discussion of a government-fixed price of 85 to 86c. It is probable that the immediately pressing need of India was satisfied by purchases made for the account of Russia during the past year. However, the crisis has not been permanently relieved, in fact, it has merely been postponed, and unless it is met fairly by international government control, meaning bi-metallism, it will occur with increasing acuteness, and, instead of having a stable value for silver and a permanent exchange rate, the whole credit fabric of the world will be subject to wide and disastrous fluctuations. That such international action will be taken in the near future is beyond doubt, and that the United States must and will take the lead seems equally apparent.

The only immediately available large supply of silver is that held by the United States Treasury against outstanding notes. A feasible plan for the release that is now strongly urged is for the U. S. government to immediately contract with the producers of silver in the United States, Canada, and Mexico, for the future delivery of their production of silver at a fixed price. The United States will then issue certificates against this future supply, authorizing the Federal Reserve Board to issue certificates to redeem the present outstanding silver certificates. In this way, the enormous silver reserve in the U. S. Treasury will be made immediately available to relieve the world's credit tension and incidentally prove a source of strength to ourselves and our Allies in the prosecution of the War. It is understood that the representatives of 90% of the silver production of the three countries mentioned have expressed their willingness to sell their future production to the Government at a price of \$1. Under such a plan it is anticipated that the U. S. government will become the sole purchaser of silver, and, as such, will be the sole distributor. This action will relieve the pressure and stabilize the credit basis for a time, at least for the duration of the War, and will permit the contemplated

international action which by the re-monetization of silver will prevent future exchange disturbances. The demand is such that, in consenting to deliver future silver at \$1 per ounce, the producers are performing a patriotic act, and it is further believed that this price is sufficiently high to stimulate the production of that metal to the utmost limit. However, it is believed that the ratio established by this price is too low permanently to meet the wild demand, and that before the conclusion of the War international bi-metallism will be established and the mints of the world will be thrown open to the coinage of silver at some ratio between 20 and 16 to 1, the former figure fixing the price of silver at \$1 per ounce and the latter at \$1.2929 per ounce, and that the ratio thus established will obtain for a generation or more.

Flotation Flow-Sheets

The Editor:

Sir—For the sake of obtaining a more comprehensive understanding of the practical application of the flotation process as practised in various mills, I prepared the flow-sheet here illustrated. It has been so instructive to me, and has presented the subject from such a different

FLOTATION FLOW-SHEETS IN VARIOUS PLANTS

angle, that I thought perhaps your readers might be interested in a short discussion of the prominent points. The first thing that struck me was the fact that even at the present time, when the flotation process is in its infancy, nearly every possible combination of rougher and cleaner cells is now practised. The second observation is that, in those mills where the best work is now being done, the flotation is effected in three sets of cells, either two roughers and one cleaner, or one rougher and two cleaners. The practical application of this observation is that, in a small plant, it is far better to have two or three small machines than one machine as illustrated in Fig. 1. The small operator is likely to install a one-cell machine, for example, the R & R or the Callow cell, or perhaps a group of M. S. cells where the pulp flows through the machine to waste. This is poor practice, because, should conditions of feed change, there is no automatic correction as is possible if a rougher precedes or follows the cell producing the finished concentrate. It may be objected that, from any cell or group of cells, a rich and a poor product may be obtained, so that one machine may act the part of rougher and cleaner, but this is seldom satisfactory.

The reduction of the tailing-loss is, broadly speaking, a question only of the amount of treatment given the pulp, but this multiplication of cells calls for more power, labor, and oils; therefore, the small mill for economical reasons must limit the number of machines. For this class of mill two machines, arranged either as in Fig. 2 or Fig. 3, will form a good combination. Fig. 2 is desirable, the pulp flowing from the cleaner to the rougher, and the concentrate flowing in the opposite direction. This may be termed a counter-current flotation flow-sheet, an example of which, with three sets of cells, I have failed to find in existing plants.

The combination found in Fig. 3 would appear preferable to that in Fig. 2. It is employed by the Arizona Copper Co. and at the Gold Hunter mill, but unless the first cell is working successfully there is no second chance of recovery. The disadvantage in No. 2 is that a variation in the amount of uncleaned concentrate and oils from the rougher cell immediately affects the finished product. The mill in which I am interested contains four M. S. and two Hebbard cells for cleaners, and a new revolving disc-machine, which throws off an excess of dirty precipitate for a rougher arranged as in Fig. 2. Any variation in the feed to the M. S. cells immediately affects the disc-machine, and this in turn reacts on the M. S. machine, thus compounding the injury. The remedy is to maintain conditions of pulp-feed.

When a set of three cells in combination is considered, it is possible to throw off the waste from the first, second, or third set of machines, always from the roughers, while the tailing from the cleaners may be returned to one of the roughers or to a cleaner. If classifiers or tables are introduced in the circuit, another set of conditions is produced by eliminating the concentrate or waste, or both, from further treatment and by returning only a middling to the flotation machine. Fig. 7 is the Inspira-

tion flow-sheet, showing classifiers and tables after the first roughing machines. The Bunker Hill & Sullivan scheme is represented by Fig. 5, and the Silver King by Fig. 6.

Mill-Tailing and Navigable Waters

The Editor:

Sir—Believing that it is the opinion of most people interested in gold mining in California that the order of the War Department forbidding the emptying of tailings from crushing-mills into the streams tributary to the navigable waters of the State is unnecessary, and therefore unjust, I ask space in your columns to propose a method of relief for the mining industry.

Stated in its simplest terms, it is that the mills should be allowed to discharge their tailings into the streams, as heretofore, and the owners assessed, on their tonnage, for the cost of disposing of the material by dredging after it has reached navigable waters. The material from the mills is a very small proportion of the total solid material that is carried into navigable waters each year from the mountain and foot-hill districts. In times of heavy rains the quantity of natural debris carried down by mountain streams is now very great; and as deforestation proceeds, and the acreage of tilled land increases, this quantity keeps increasing also. It seems likely, therefore, that in order to keep the navigable waters in condition to serve the needs of the rapidly increasing population, and consequent commerce, of the State, it will be necessary to maintain in perpetuity a system of dredging.

It is beyond dispute that the tonnage from the mills that reaches the navigable waters and finds lodgment there cannot be more than the original quantity put into the streams—and may be appreciably less—and it should not be a difficult task for the Federal authorities to get from each mining company correct returns of the tonnage crushed.

I have no figures on the cost of dredging, but my scheme of relief is based on the assumption that it is very low where large quantities of material are handled—much lower than the cost would be, in most instances, to impound the tailing at the source. Indeed it seems to me that in the case of mills situated in deep and steep canyons the order must be nearly prohibitory.

Mining is a legitimate industry, and should be fostered rather than hampered by both the Federal and State authorities; and if it damages any other interests, these should be given relief in the manner least burdensome to the miner.

This solution of the question may have been proposed before and turned down as impracticable. If not, and this letter should open a discussion of methods for the disposal of the tailing, my purpose will have been served.

Grass Valley, January 29.

Canvas Tubing for Mine Ventilation

By LESTER D. FRINK

*Metal tubing, with blower or exhaust-fans, has long been used in supplying air to dead ends where natural ventilation is impossible, or in driving the smoke from such places, or in doing both, as the need might be. In

the jointing of sections and in the manner of suspension have so increased its usefulness that it promises to add much to the efficiency of mining. A product is now on the market that is impervious to air, is fire-proof, and

FIG. 2. CANVAS TUBE KEPT IN THE CLEAR WHERE METAL TUBE WOULD BE DIFFICULT TO PLACE

Butte canvas tubing is now used extensively because it is found that it has many advantages not possessed by the metal. Although the use of flexible tubing is not new it has not been generally used in mining operations. Recent improvements, however, in the canvas itself and

has a system of jointing that permits it to be put up or taken down in a few seconds. This article explains the manner in which canvas tubing is being used in the North Butte Co.'s mines at Butte, Montana.

Early in 1916, the work of deepening the Granite Mountain shaft from the 3100 to the 3700-ft. levels was

*Abstract: Bull. A. I. M. E., Feb. 1918.

commenced. A good crew was secured and satisfactory progress was made for a few months. Conditions, however, became increasingly unfavorable as greater depth was attained, the men whom we considered the best workmen dropped out one by one. In June only 60 ft. of advance was made, and it was evident that some means of bettering conditions must be devised. The advance in July of but 50 ft. left no doubt that the remaining 150 ft. would take a long time if the efforts to ventilate did not prove successful.

The Granite Mountain shaft is a down-cast; there is a good supply of air on the 3000-ft. level; a fan with galvanized tubing running from the 3000 down the shaft in the pump-end of the chippy compartment had been considered. Those that have had experience with galvanized tubing are fully aware of its drawbacks. It goes together slowly and there are always many leaky joints; it is flattened easily by concussion and is often ruined, even when care is taken not to bring it too close to the blast. Knowing these drawbacks to the use of the metal, the engineers in charge decided to try canvas tubing. This had no attached means of joining sections. Connections were made by slipping two ends over a 6-in. metal hoop and holding the canvas in place by wiring it. When two lengths were joined in this way it took but a comparatively slight weight to pull the sections apart, and probably concussion would have worked the same result. Later a joint was designed that met every condition imposed upon it (see Fig. 1). It will not only support the weight of the canvas, but will hold a much greater load, as was shown in many tests, men even swinging their full weight on the lower section. It is reversible, and also has the advantage that it can be taken apart or put together while the fan is running. The canvas covering the ring, being sewed in at each end of each length, acts as a gasket and prevents leakage of air. Each ring has a slip-joint, and the rings are made the same size so that either may be put within the other by contracting one ring. When placed together they form a circular channel. Each length of tubing comes with such a ring sewed in at each end, and when two are put together the canvas forms the gasket to prevent leakage. In drifts and cross-cuts, tension-bands, similar to the suspension-ring used in shaft-work, are put over the joints at required intervals; slack in the tubing is taken up and it is prevented from drawing back by wiring the tension-band to the clamp that grips the messenger-wire. The stronger the pull, the tighter the grip. Supporting rings were made from galvanized iron. These were put over the joints. The tubing was hung in the shaft by wires. At the first trial, 500 ft. was taken down, and one could not help noting the advantage in handling it as compared with the metal tubing, when three men and the total length were put on the cage together. An equal length of galvanized iron would make about eight deck-loads. Within two hours the stringing of the canvas was done and the fan was put to work.

It is not always safe to accept, as their true opinions,

what miners say to your face, but after a shift or two the best men were back again looking for a place in the shaft, and we knew then that working conditions had improved and that better results could be expected. In August we made 132 ft. of advance and the 20-ft. sump below the 3700 was cut in a few days in September. By using pieces of different length, the tubing was kept as close to the bottom as the shaft-men wished. Of course, in adding lengths the lowest piece was always removed and the new piece placed above it. By doing this a blasting-piece was always kept at the bottom and stood the abuse when a round of holes was spit. No great difficulties were experienced in the use of the tubing in the shaft. From time to time the supports had to be lowered because the cloth had stretched, and there were a few holes to be sewed up where the tubing was cut by flying rocks, but more often the supports had to be lowered when starting the fan after it had been stopped during timbering. Velocities of the air taken at the discharge averaged a little over 5000 ft. per minute. Rock temperatures in drill-holes on the stations at the 3600 and 3700 ranged between 100 and 105° F. Judging from the volume of air delivered at the bottom of the shaft and from the fact that the men at the bottom would not let the lowest length be kept down close to them, I am sure that the No. 4 Sirocco fan used for blowing through a 16-in. tubing was larger than necessary.

Success had been so complete in the ventilation of the shaft that it was decided to put a fan and some tubing in a cross-cut being driven to the Rainbow mine. The problem here was different. Water temperatures taken near the breast gave 65° F. This is probably pretty close to the rock temperature. While this is all that could be desired as a working temperature, the accumulation of powder-gas at the breast made it impossible to maintain a full shift, and rounds were repeatedly lost. The difficulty was not to cool the place but to clear it of smoke. The breast was 2100 ft. from the nearest supply of air, an up-cast raise with a temperature considerably higher than at the breast of the cross-cut. A fan-house was erected over this raise, and 16-in. tubing run to a booster fan 1500 ft. away. Here it was picked up and sent through tubing to the breast. Though the joints between sections were the same here as in the shaft, the means of support was necessarily different. A messenger or suspension wire (No. 8 galvanized) was stretched with the aid of the common 'come along' used by the electricians in putting up trolley, the ends being fastened to stulls in the cross-cut. At convenient places, from 25 to 40 ft. apart, sprags were put up and the messenger stapled to them to prevent sag. In the hem of the tubing, at intervals of three or four feet, two grommets or eyes were inserted, and in these were fastened wire-clips or hangers. By means of these hangers the tubing could be hung rapidly to the messenger and made fast by bending the hangers together with a nail, the carbide-lamp stick, or any pointed tool made for the purpose. Between the sections a tension-

band similar to the suspension-ring used in the shaft was placed over the joints and when the slack was taken up it was wired to a clamp that caught the messenger and prevented the tubing from drawing back. The fan when started delivered about 2500 cu. ft. per minute at the end of the line.

Next morning when we went to see what results were

FIG. 1. JOINT FOR CANVAS TUBE

being obtained, we found that each low place in the tubing was a reservoir, weighted down with water. We had not thought of the condensation that was bound to come as the air went into cooler surroundings. The con-

ditions at the breast, however, were much better than they had been, and the shift could easily work there. Cheered by the fact, we went back along the tubing, disjoined the sections, and drew the water out. As it was

FIG. 3. A 45° BEND IN CANVAS TUBE AT THE FAN

ditions at the breast, however, were much better than they had been, and the shift could easily work there. Cheered by the fact, we went back along the tubing, disjoined the sections, and drew the water out. As it was

FIG. 4. CANVAS TUBE LEADING FROM A FAN

leakage. By shutting down the fan for a few minutes each morning, the ditch-man could run all the water to the ends, pull the corks, tie up a short section, and move on to the next joint to do the same. By the time the last sections were drained, he could start back along the line untying the canvas and replacing the corks. All would then be well for another 24 hours. Later it was found that the booster-fan was not necessary, and the tubing was connected straight through, making, before the cross-cut was finished, a 2400-ft. line.

While conditions at the breast of this cross-cut could not be made as we would have liked, because of the poor supply of air that had to be used, the place was put in such shape that a round was seldom lost and the men stayed with the job, with but few changes, until the 300-ft. advance, to hole, was made. When holed, the breast of the cross-cut was just a mile from the Granite Mountain shaft, the source of the air-supply.

This was the first line that had been run in a cross-cut and we were pleased to find how easily the tubing conformed to the bends. Where galvanized pipe would have been hard to install because of jutting rock or slight turns, the canvas passed around them in smooth curves. Elbows to fit any angle were easily made by cutting the tubing to pattern, as a tinsmith cuts elbows, and sewing the two ends together.

In the cross-cut some difficulty was experienced with the leading length until a successful blasting-piece was made. This piece was made up with harness snaps fastened to ears sewed to the hem of the tubing so that it might easily be put up or taken down. Before spitting a round of holes, this piece was detached and carried back to a safe place. This would leave the discharge far enough away from the breast to be safe from flying rocks and the effects of concussion, and still close enough so that the smoke would be driven out quickly. When the next shift came on, they would replace the blasting-piece so that the air might blow directly on them.

On the 3000-ft. level in a drift we are able to supply good air to the breast with a No. 2½ Sirocco fan blowing through about 500 ft. of 10-in. tubing. In this length there was one place where the water ran on the tubing in streams. The canvas showed no ill effects from the bath. The cost per linear foot of driving was reduced about 50% in this drift and no difficulty was experienced in keeping men. It was here learned that air-motion was a great factor in making favorable working conditions. There was but a slight difference in the temperature and humidity of the air as it blew on the men and that of the drift 50 ft. back where the air velocity was low, still the men felt comfortable and could work at the breast, whereas little could have been accomplished if the work had to be done 50 ft. back. One miner, in referring to this fact, said he could easily understand it, for when a day was hot and unbearable if he went out in his 'auto,' as soon as he got up a little speed, he was cool enough. It would be hard to get the men to move as fast as that underground, but the air can be made to move, as is attested by velocity readings of

4000 to 5000 ft. per minute recorded at the discharge of most lines not over 500 ft. long.

On the 3200, 3400, and 3600 levels, considerable use has been made of the canvas tubing in blowing to the breasts of the cross-cuts. The rock temperatures on these levels are quite high, being 100° F. at the 3200, 102° at the 3400, and 104° at the 3600. As yet a separate fan has not been put on each of these levels. All the air is supplied by a No. 6 Sirocco fan blowing from the 3000-ft. level. An air-box has been placed in one corner of the pump-compartment of the shaft. At each level, part of the air is taken out and direct connection is made to the flexible tubing that runs to the breast of the cross-cut. These headings have advanced about 300 ft. on each level. In spite of the high rock-temperatures, the working conditions at the breast have been kept comfortable. By having at each working-place a number of short lengths, the men can bring the leading piece as close to them as they wish. When the short lengths are all in use, a long length is sent down to take their place. This order of changes is repeated time and again as the work progresses.

Ten and twelve-inch tubing is used on these levels. We have found that the tension-rings, used in connection with the clamp that grips the wire, and of course the clamp too, are not necessary on the smaller tubing. When they are not used, the clips that are bent around the messenger-wire to support the tubing must be tightened carefully.

Considerably more care must be exerted in the use of the canvas tubing for ventilating raises than need be taken in cross-cuts or drifts. Where the rock temperature is high, it will be found that added advance and the consequently diminished cost will repay amply the time spent in placing and protecting the tubing. In all the vertical portions of the raises, it is found necessary to box the tubing for protection from falling rocks. These boxes need not be air-tight and can quickly be thrown together out of inch material. At the offsets the tubing need not be covered. The discharge from the top box must be covered with a screen to keep falling pieces from going down the tubing, and it must be especially well protected when blasting.

Being close to a current of good air does not always make a good place to work. A stope was started on the 2600 directly over a cross-cut that was a main air-course. On the first floor the conditions were good, on the second floor the stope was a poor one to work in, and the third floor was so hot that but little was accomplished, though neither end of the stope was 50 ft. from the main air-course. There being no working on the 2400 to hole to with a raise, natural ventilation was impossible. A No. 4 Sirocco fan with a 20-hp. motor was placed at the cross-cut and the air was taken through a 16-in. tube up a man-way and turned directly on the men in the stope. This made it a good place to work. Often stopes such as this must be worked until connections can be made with other levels, and the use of blower-fans seems to be the best alternative.

In one stope with ample connections between levels a No. 4 fan and 16-in. tubing completely reversed the air-currents, with a resulting drop of 15° . This good result was accomplished without causing any apparent ill effect in our other workings.

In places artificial ventilation is needed only for a short time, while a raise is being put through or a cross-cut or drift is being extended. Such work may take a month or less. Conditions may be normally such that it is impossible to hold men in these places. The short period of time that we need to have a fan blowing, before natural ventilation can be attained, has made us hesitate to put in a concrete foundation. Wood foundations we have tried to avoid for all electric machinery, on account of fire risk. As motor haulage with direct current is used almost entirely, and as the trolley-lines reach almost every part of the mine, we have mounted some No. 2 and No. 3 direct-current fans on trucks. Such fans, mounted on a heavy plate and arranged so that they may be turned to any angle (in a horizontal plane) with the trucks, make a satisfactory equipment for use in these places. One, complete with its auto-starter and the canvas tubing, is run to the place where needed; here it is thrown (truck and all) from the track, or placed on a siding; a messenger-wire is strung; connections are made for the electric current, and the fan is started with but comparatively little trouble. These fans are moved from place to place and in a short time will save, in labor and foundation material, the cost of the truck and time of mounting.

The examples that have been given all refer to places of considerable depth. A word might be said concerning our north-western tunnel, where a fan and tubing was used. I hope my words may in no way detract from the credit due to the foreman in charge for the good work he did. While the rest of the machinery was being installed, it was thought advisable to erect a fan at the portal, and it was but a short time before the need of it was evident. Three shifts of 8 hours each were worked and in 3 months time but one shift missed blasting and that round was made up in the next 8 hours. In November 446 ft. was driven, December's advance was 477 ft., and in January 510 ft. was made. The work was done with four men per shift at the breast, two miners and two shovelers.

It is hard to estimate how much aid the blower-fan and tubing afforded in making this advance, but it is safe to say that almost an hour per shift was added to the working day. Sometimes this must have made the difference between getting a round and losing one. It always meant that the round could be a little deeper. Both of these things have their dollars and cents value, whether we can figure the exact amount or not.

Within the last few months, many improvements have been made on the tubing. The first that was sent us from the factory was coated on one side only, had no means of support and an inconvenient and inefficient means of connecting lengths. As shipped today, the

tubing is coated on both sides, has a wide top hem in which at intervals of but a few feet are grommets and suspension clips, and the ends of each section are provided with coupling-rings that make its installation simple, rapid, and satisfactory.

Royalties on Iron Ore

In the Lake Superior region of the United States, which produces approximately 85% of the total iron ore mined in the country, owners of mineral lands usually do not operate their properties themselves, but lease them to the mining companies on a royalty basis. Lake Superior iron-ore royalties, as a rule, have not been based strictly on the metal content of the ore, but rather on the favorable or unfavorable conditions of mining, the size of the ore deposit, and other variables of an intangible nature. Actual royalty payments on iron ores may vary from 10c. to \$1 per ton of ore as mined. The higher royalties usually indicate that the deposits contain high-grade ore existing under favorable conditions for mining, while the lower royalties indicate that the ore is of lower metal content or that the mining conditions may be more difficult. Royalty represents merely a division of the total profit on the production of iron ore, which has been commanded by the strength of the position of the fee owner of the property. The total profit is represented by the sum of the royalty and the net profit to the operating company. There is, as yet, little tendency toward standardization, and there probably never will be, as it is a question not only of metal content, but of metal content considered in connection with the cost of mining, transportation, and other conditions.

A RAPID method for the analysis of zinc alloys is given by Mossbacher in the Journal of the Chemical Society. The routine consists in dissolving the alloy in concentrated nitric acid, evaporating to one-third its original volume, dropping sulphuric acid into the centre of the liquid, and heating until a white fume is given off. Add H_2O and $EtHO$ and allow to stand several hours until the lead sulphate has settled. Ignite the precipitate in a crucible which has just been heated with a drop of sulphuric acid. Precipitate the copper as sulphide, and heat with sulphur in hydrogen, using a silica crucible. Precipitate the alumina and iron from the filtrate, after removing H_2S by adding H_2O_2 , and then quickly a large excess of NH_4OH . The iron is estimated volumetrically in a separate portion.

ANDALUSITE has been found in pre-Cambrian rocks in the Inyo range in California, as a segregation 500 ft. wide and extending to a known depth of 300 ft. It is traversed by stringers of quartz carrying lazulite, a deep blue hydrous phosphate of Al, Mg, and Fe, containing about 45% P_2O_5 . The occurrence has been described by A. Knopf in the Journal of the Washington Academy of Sciences.

Calumet & Arizona Safety Rules

Since 'safety first' has taken rank as part of our economic culture the usual tendency to excessive detail and non-essential refinement, which is of the same order as academic exaggeration of unimportant learning in the colleges, has at times given the propaganda a touch of the ridiculous. The zeal of State officials may easily go too far in the regulation of industry in some directions, while failing to provide against other and more real dangers because of inexperience with the conditions that the workman daily meets. It is, therefore, of interest to the mining community to know what practical safety-regulations are deemed essential by one of the largest and most efficiently managed corporations in the country. The following rules, printed for the use of the underground employees of the Calumet & Arizona Mining Co. and its allied companies, represents a guide that has been evolved from the facts accumulated during years of economic administration by capable men. The pamphlet is given in full.

INTRODUCTION

More men are killed or injured in our mines from falls of rock or ore than from any other cause. The Calumet & Arizona Mining Co. and allied companies are doing their utmost to prevent these accidents, and they require that every employee exercise the greatest precaution for his own safety, as well as the safety of his fellow-men. A mine equipped with thousands of dollars worth of safety devices and worked by careless or indifferent miners, will have more accidents than a mine without a single safety device, but with miners who are always thinking of preventing accidents to themselves and their fellow workmen. It is often the case that unskilled laborers are ignorant of danger and do not know how to take care of themselves. This company asks the more experienced men to protect that class of labor by making conditions safe for them and by not permitting them to endanger themselves. A careful study of many accidents indicates that a large proportion of the accidents might not have happened if the miner had used more judgment or care. It lies within the power of the underground worker to reduce greatly the number of accidents. The exercise of this power is a duty that every miner owes to himself and to his fellow workmen. Remember to be careful under all circumstances. Keep in mind at all times the necessity of care. When caution becomes a habit there will be but few accidents. Always think before you act. Employees must familiarize themselves with these rules. Failure to observe the rules is sufficient cause for discharge.

UNDERGROUND RULES

MINING. Timbering must be done at once as soon as the ground requires it.

Timbers must be watched and kept safe.

Miners must always bar down the roof and walls when necessary, and must not permit the shovelers or other employees to work under a place until it has been tested and made safe for them.

Before starting to work in a cross-cut or other place designated by the shift-boss every shoveler must examine the sides and back of that place of work. If it is beyond his power to make the place safe he must notify the shift-boss or do other work until the shift-boss arrives.

In stopes worked by the square-set method the working-floors shall be securely lagged overhead and underfoot, and in all stopes guard-rails must be placed where needed.

Every miner must examine the working-face for missed holes before he starts to drill his round. Do not start to drill before this is done, no matter whether or not a missed hole had been reported.

Do not set your machine-bar under bad ground. When this is done there is danger of an accident when you are taking the bar down again.

Every employee whose duty requires him to work with any appliance must report any defect, if found, to his shift-boss or foreman.

When working heavy or untimbered ground, care should be taken that there is plenty of room for a quick exit. All obstructions, such as cars, wheelbarrows, timber, and so forth, should be moved out of the way.

Planking over sumps and ditches must be kept secure.

No candle or lamp shall be left burning in a mine when the person using the candle or lamp leaves his work for the day.

Lights must be placed so that timbers cannot catch fire.

Employees shall inform the foreman or shift-boss of the unsafe condition of any working-place as soon as that condition is discovered.

Chutes shall be protected so that men cannot fall into them.

Men are strictly forbidden to carry tools, rails, pipe, and the like, upon their shoulders in any drift where electric wires are installed. This rule must be closely observed.

RAISES, WINZES, AND LADDER-WAYS. Any raise or winze now opening from below directly on any drift or cross-cut traveled by men shall be covered by a grizzly or by doors. The opening of offset winzes shall be protected by a fence or guard-rail not less than three feet and not more than four feet above the level of the drift.

Defects in ladder-ways must be reported immediately.

It is a serious offense to remove a ladder that is used as an exit.

Ladders shall not be removed from their usual place without orders from the shift-boss.

All perpendicular ladders must be securely fastened with ladder-hooks.

Employ care in placing ladders before using them. If there is danger of a ladder slipping, have it securely fastened before using it. Any ladder-ways, raises, or manholes found unprotected or out of repair shall at once be closed and kept closed until put in repair.

Suitable landings or platforms shall be put at the bottom of all ladders and the place where ladders are offset.

In all raises wherever possible, ladders shall be placed on an incline, with suitable landings.

In hoisting or lowering timber or tools in a manway, they shall be securely lashed, and care must be taken that no one below is in danger.

Men are positively forbidden to throw tools or material down manways.

Men are warned against going down a chute to repair it without first notifying the men above, and then it must be securely lagged overhead.

Do not go up into a chute where ore or rock is hanging in order to blast it. Do your work from the manway by taking out a lagging if necessary.

All chutes, manways, winzes, raises, and other openings shall be covered by a substantial hatch, planking, or grizzly, or provided with guard-rails or chains, and shall be kept in such condition that men cannot walk into them.

When advancing a raise be sure to have the chute and the manway covered until ready to blast. Do not run chances of falling down the chute while drilling or timbering.

EXPLOSIVES. Powder-nippers shall be very cautious in the handling of explosives, both underground and on the surface. Before using the railroad or motor-tracks they shall make sure that they have the right of way. They shall use extra care in handling powder on cages and in all other places.

When explosives are delivered near the shaft of a mine a representative of the company must receive the same and see that they are safely placed.

Giant caps shall not be transported in the same vehicle or carried in the same case with dynamite or other explosives.

Giant caps shall not be stored with explosives.

No explosives shall be taken into any mine except in a securely covered case.

Men must not ride on the cage when powder is being lowered, except when it is being taken from one level to another, and then only the cager and powder-nipper may ride with the powder.

Powder must not be left on the station, but must be taken to the magazine at once.

In tamping drill-holes wooden rammers only shall be used. Tamping by strokes is forbidden and only direct and steady pressure permitted.

No steel or iron tools shall be used in tamping.

Cap-crimpers shall be furnished and must be used.

Crimping with the teeth is dangerous and is forbidden.

Skewers shall be furnished for the use of all miners handling explosives, and shall be used for making holes in the powder for the fuse. No candle-sticks or other instruments shall be used for this purpose.

A miner shall never be alone when blasting, but must keep at least one man with him. Miners preparing to blast shall have a reserve light near a manway or some other convenient place in case their lights go out after spitting the fuse.

Miners about to fire shots shall cause warning to be given in every direction. All entrances to the place or places where charges are to be fired shall be guarded while such firing is going on.

The number of reports shall be counted by the miners firing them, and mis-fired holes shall be reported to their shift-boss. If at all in doubt it is better to report a missed hole than to have a missed hole and not report it.

No one shall be allowed to enter a working where there is believed to be a missed hole for a period of at least 30 minutes.

Do not extract nor attempt to extract explosives from a hole which has missed fire, but in every case insert a fresh charge above the missed explosive and then fire it.

Where boulders are being blasted by placing explosives on said boulders, and not in holes drilled for that purpose, employees shall see that the powder is well covered with clay or some other suitable material, so that it cannot take fire.

Any powder not used by the miner on his shift must be taken to the magazine or place prepared for this purpose. Leaving powder in a working-place will not be tolerated.

Do not use a short fuse to hasten the explosion, or with the idea that it is economical to do so.

Powder and capped fuse must be kept separate when hoisting into a stope.

When opening a box of dynamite a wooden chisel and wooden mallet must be used.

Using fuse for belts is forbidden.

ELECTRICAL EQUIPMENT. Every workman not duly authorized by the chief electrician or his assistant is forbidden to work or tamper with any electrical wires or machinery.

When a circuit is opened to allow repairs, a danger-signal must be securely fastened to the switch, giving the name of the workman who is employed on the line.

The signal must not be removed until notice is received from the workman.

The insulation on electric wires cannot be depended on to protect you from shocks.

All alternating-current (A. C.) power-feeders should be handled with great care; the voltage is high enough to be fatal under certain conditions. An experienced man may handle these circuits while they are alive by using proper precautions, but it is much better to cut off the power when possible.

Avoid working on any live circuits as much as possible.

Never handle electric wires while standing or sitting

in a wet place, without extra precaution to insure insulation from the ground.

In handling any circuit known to be alive, use only one hand when possible. It is best to keep the other behind the back. The most dangerous shocks are those from hand to hand.

So far as possible treat all circuits as though they were alive, even though you may believe them to be dead.

Tape the handles of your tools to prevent short circuits across them.

The trolley-pole must follow instead of leading the motor, except in places where it is impossible. The motor must go slowly when it is necessary to have the trolley-pole ahead.

The trolley-pole must not be turned while the motor is in motion.

There must be a red light on the front end of all trains that are being pushed through the drift.

The bells on the motor must be kept in good working order, and must be allowed to ring while the motor is in motion. The motor-man must notify the electrician when bells get out of order.

No one except motor-men and electricians are allowed to run a motor.

Only motor-men and brakemen are allowed to ride on a motor, and no one is allowed to ride on the cars of a motor train.

Motor-men, or men running a motor, shall report to the electrical foreman, mine foreman, or shift-boss, any defective condition of the electrical equipment underground.

All trolley construction or repairs underground must conform to the State laws of Arizona.

All electrical apparatus and conductors shall be of sufficient size and capacity for the work they may be called upon to do, and so installed, operated, maintained, and safeguarded as to reduce the danger from accidental shock, or fire, or overheating, to the minimum, and shall be of such construction and so operated, that the rise in temperature caused by ordinary working will not injure the insulating material.

CAGES. At no time shall more than nine men be permitted to ride on one deck of a cage at any of the mines, except at the Junction and the Cole, where 12 will be allowed.

Employees are forbidden to crowd around the shaft before the station signal to hoist men is given. After the signal is given the men must stand in line and not nearer than five feet from the shaft. No crowding will be tolerated.

Safety-gates must be kept closed when men are being hoisted or lowered, except when timber is being handled and the gates cannot be closed. This applies to one or more men. All lights must be extinguished before getting on a cage.

No smoking will be allowed on the cages.

When using the cage all signals shall be given while standing on the cage and not on the station.

When a cage is to be released the release signal shall be given while standing on the station and not on the cage.

Riding on a cage, skip, or bucket, loaded with tools, timber, powder, or other material, is absolutely forbidden except when necessary to assist in passing such material through a shaft, and then it is allowed only after the engineer has been notified.

When tools, timber, or other material are to be lowered or hoisted in a shaft, their ends, if projecting above the top of the bucket, skip, or other vehicle, shall be securely fastened to the hoisting rope or to the upper part of the vehicle.

In no case shall a cage, skip, bucket, or other vehicle, be lowered directly to the bottom of the shaft when men are working there. Such cage, bucket, or other vehicle must be stopped at least 15 ft. above the bottom of the shaft, until the signal to lower further has been given to the hoisting-engineer by one of the men at the bottom of the shaft, provided, however, that this rule shall not apply to shafts less than 50 ft. deep.

Riding from level to level on a cage containing a loaded or empty car is forbidden.

The cage-men and top-men shall keep a careful watch over the cages during their shift's work, and immediately report all defects, and have them repaired before continuing their work.

No person shall get off or on a cage while the same is in motion.

No men can be lowered on a cage without a bonnet.

SHAFTS. No hoisting shall be done in any compartment of a shaft while repairs are being made in that compartment, except such hoisting as is necessary in making the repairs.

When men are working in shafts, suitable covering shall be provided to prevent material from falling down the shaft.

The shaft-gates or bars must be kept closed except when in use.

If either of the two systems of signaling is out of order, extra care must be taken and a report made at once.

If an employee drops any material or tools down the shaft he shall immediately report the same to the hoisting-engineer, who will have the shaft inspected before continuing with the regular work.

SIGNALS. The regular code of bell-signals must be strictly followed.

Cages going from level to level must always give the signal for men on the cage.

All men are forbidden to use the bell-cord for calling a cage, but must use the flash-bell. Signs are placed at each station calling attention to this rule.

In order to receive compensation all injuries must be reported to the shift-boss or foreman, or have the cages report for them, before they leave the company's property.

FERRO-MANGANESE containing as little as 20% manganese is now being used in open-hearth converters.

Sharpening and Distributing Drill-Steel

By HOWISON CROUCH

The present system of distributing drill-steel at the Empire mine, Grass Valley, California, has been in use 20 months, and the results have been so favorable as to warrant a brief description. It was developed to overcome the weakness of the old method, which became apparent when the milling capacity was increased and greater tonnage demanded. Under the old system, sharp steel was sent down in the morning for the use of the day shift, and the steel that had been dulled on the pre-

picked up the same trip. Gates are provided at the collar of the incline shaft, and the trucks, loaded with dull steel, are run direct to the tool sharpener's shop, where it is sorted and counted. After sharpening and tempering, it is replaced on the truck according to a tag, which will be mentioned later, sent from underground by the tool-boy. Any shortage due to breakage, or any extras demanded, are provided from the stock-pile, which is supposed to be kept adequate for all emergencies.

DRILL-SHARPENING EQUIPMENT, EMPIRE MINE, GRASS VALLEY, CALIFORNIA

vious night shift was brought up. Part of this dull steel would be sharpened and sent down again in the afternoon for the use of the night shift. In spite of this apparently active circulation, the miner was often kept waiting for steel. If he was not lacking in the number of drills he was likely to be short of the desired lengths. Under the new system enough steel is provided for two full shifts in each stope. The sharp steel is delivered to each level but once a day, this being the last thing done before the night-shift men are hoisted, and is part of the duty of the skip-tender and helper.

The steel is handled on two trucks specially made for the purpose, with compartments for keeping the allotments for the various levels separate. The dull steel from the previous two shifts is on the stations and is

Each tool-boy is provided with a book, conveniently ruled and furnished with carbon, in which, as he visits a stope on any particular level, he records the number and the lengths of the dull drills taken out. After he has visited all the stopes on a level, he tears off a tag from his book, which is given to the mule-driver on that level, showing the number and lengths of sharp steel to be delivered from the supply at the stations to the steel-racks provided at the manways leading to the stopes. The rest of the leaf of the tool-boy's book is sent to the shop, and shows the number and lengths of sharp steel to be put on the truck in the proper compartment for that level. The broken steel is also recorded and a similar piece substituted when the truck is loaded.

The theoretical result is that each stope is always

provided with enough drills of the right kind. Each level and stope gets back on the next truck the same number and kind of sharp drills that were taken away dulled on the previous day, including the broken steel. The actual result approaches this condition quite closely, considering that four different sets of men handle the business; also due allowance must be made for carelessness and indifference. The six levels from 3000 to 5000 ft. inclusive are visited by two tool-boys, who collect and record the dull steel from the working-places. The ore-bodies are, in most cases, at a considerable distance from the shaft; consequently the steel must be transported on each level for distances varying from 1000 to 4000 ft., and must be collected from and distributed to three to twelve working-places.

The pitch of the vein is about 40° , and, therefore, to facilitate the handling of the dull steel in the stopes, slides have been placed in the manways, through which the steel is delivered to the level below, proper precautions being taken, of course, to avoid accidents. A detailed count of all steel underground and in the shops is made once every three months. The total number of pieces has remained nearly constant, refuting the objection that if an abundance of steel were furnished, there would be a high percentage of loss. The number of the longer lengths decreases, due to breakages, while the number of short drills increases. The short lengths recorded as being rejected because too short for use, correspond closely to the number of pieces of new steel cut. The record of broken drills seems to show that, when there is a shortage of drills in a stope, the percentage of breakage increases.

Hammer stopers, using solid steel and a cross-bit, are used in the stopes, while the driving is done with water-machines using hollow steel with a cross-bit. There is a considerable variation in the character of the ground drilled, both in the drifts and stopes. The foot and hanging walls, in the lower levels, are grano-diorite, and in many cases the fissure is not wide enough to afford suitable working space, and the drilling must be done in one or the other wall. Sudden increases in the hardness of the ground, especially in the drift, sometimes causes a heavy demand for drills, but if the stock-pile has not been neglected, the emergency is readily met.

The tool-shop equipment consists of two No. 5 and one No. 3 Ingersoll-Rand pneumatic sharpeners, and one pneumatic punch of the same make, for clearing the holes in the hollow steel. Concrete tanks, with screens near the bottom, are used for tempering. Crude oil is used for fuel in the furnace, which is of the ordinary type, enclosed with a substantial brick wall, having openings on three sides, and provided with a hood and large flue for carrying off the waste heat. The structure itself is built of steel, no wood whatever entering into its construction. Worn T-rails were used for the frame and rafters, to which the roof and sides of corrugated iron are riveted. The dimensions of the building are 45 by 30 ft. with eaves 15 ft. high, giving plenty of

air-space, and producing the maximum of comfort for the men. The work of the shop is done by three operators and two helpers, working eight hours per day.

A daily record is kept of the work done, including new steel cut, and while the amount varies somewhat at different periods, on account of fluctuating demand for drills, it will be fairly well represented by the three months of June, July, and August 1917. During this period, in which there were 79 working days, a total of 51,029 pieces of steel were handled, or an average of 645.9 pieces per day. An itemized statement of costs follows:

COST PER PIECE	
	Cents
Labor	2.56
Crude oil	0.24
Compressed air	0.24
Furnace repairs	0.03
Sharpeners repairs	0.01
Miscellaneous	0.01
Total	3.09

CATALYSIS has been defined ironically as a screen behind which chemists hide their ignorance. W. A. Tilden defines it as "a process in which a chemical change, which, without assistance proceeds either not at all or very slowly, is greatly accelerated by contact of the materials with a small quantity of some agent, called the catalyst, which after the reaction remains undiminished." This is labored, but it is hard to improve it. For many years catalysis was hardly known outside of the laboratory, but now it is coming into use extensively in industrial chemistry. The most familiar case probably is the contact method of making sulphuric acid. In this process the sulphurous anhydride from the sulphur-burners and the air, which would remain intermixed almost indefinitely without appreciable reaction, will immediately combine when passed through platinized asbestos, forming sulphuric anhydride, and yet the finely divided platinum undergoes no change. Catalysis is used today in the manufacture of synthetic ammonia, in the oxidation of ammonia to nitric acid, also in the hydrogenation of oils for the manufacture of soaps, and in a number of other chemical processes.

TUNGSTEN production from the Boulder district, Colorado, is now about 100 tons per month of 60% concentrate. During the earlier part of 1916 the monthly output never fell below 250 tons. It is said that the tungsten in the Boulder mines has been found not to be persistent as a rule below 250 ft., the older properties being practically exhausted, and the present supply coming mainly from the newer mines.—'The Mining American.'

FLINT is frequently a result of deposition of silica concurrently with the solution of calcareous bodies, remnants of which may sometimes be seen in flint sections. The Australian flints are often crowded with the silicified remains of polyzoa, foraminifera, shell-fragments, and occasional sponge-spicules.

The Metallurgy of Nickel

*Although a small quantity of ferro-nickel is produced by the direct smelting of New Caledonian and other oxidized nickel ores, practically the whole of the nickel ore throughout the world is reduced directly in blast or reverberatory furnaces to a low-grade highly-ferruginous matte. This is afterward converted, or bessemerized, to remove nearly the whole of the iron and as much sulphur as is possible without excessive loss of nickel or nickel-copper when the latter metal is present in the ore. The process is similar to copper smelting except that, instead of producing blister metal, the nickel smelter produces a high-grade matte carrying about 75% nickel when non-cupriferous nickel ores are smelted, and as high as 85% nickel when the copper content of the ore is greater than the nickel content. An attempt to produce a higher-grade matte is fraught with considerable loss, owing to the great affinity of nickel for sulphur, causing the matte to freeze while it still contains a considerable proportion of sulphur. It is important to note that in making an 80% matte, which is the present aim at Sudbury, the loss, though temporarily heavy, is usually quite small. The loss is due to small particles of matte being projected into and retained by the slag. This loss has been overcome by mixing the converter-slag while still molten with the blast-furnace and reverberatory-furnace slags in huge settlers where, owing to the enormous bulk, the slag remains molten for a long time and gives the particles of matte ample time to settle to the bottom.

In the smelting of oxidized ores, such as those of the Caledonia, sulphur is added either in the form of pyrite, or, when there is sufficient iron in the ore, as gypsum, which becomes reduced to sulphide by the coke in the charge and forms with the iron a matte in which the nickel is collected. The matte thus obtained is refined by several different processes which will be described later.

SUDBURY PRACTICE. The Sudbury ores are of massive pyrrhotite, carrying small quantities of nickel, mainly as pentlandite, and of copper as chalcopyrite. They contain far too much sulphur for smelting in either blast or reverberatory furnaces, so a considerable quantity has to be removed by roasting before the ore is smelted. There are three companies operating at Sudbury, two of which, the Canadian Copper Co. and the Mond Nickel Co., have been producing for many years, while the third, the British American Nickel Corporation, has recently entered the field. While the metallurgy of the metal, up to the point of obtaining the high-grade matte, is in the main the same, each company has its individual methods. The Canadian Copper Co. roasts the coarse ore in heaps and the fine in Wedge roasters. Each heap contains

about 2500 tons of ore, and is 60 by 100 by 8 ft. high. In building the heap, wood, usually dead pine, is laid on the ground to a height of a foot to 18 in., and is roughly leveled; coarse ore, amounting to about two-thirds of the whole, is piled on the wood. This is followed by medium-size ore, and then by fine. The wood is lighted and burns for 60 hours, by which time the ore is thoroughly ignited and continues to burn for three or four months, requiring only a little attention to prevent too great a heat and the consequent fusion of the ore. The raw ore averages 23% sulphur, which, at the conclusion of the roast, is reduced to 10 or 11%. Some sintering or fusion takes place, and the heap often has to be blasted before it can be removed by steam-shovels into the ears that carry it to the smelter. Since there is no protection from the weather, and as some soluble sulphates of nickel, copper, and iron are formed during the operation, it is evident that small quantities of nickel and copper are leached by rain and snow. There is no accurate knowledge of the proportion of metal thus lost, but it is estimated at $1\frac{1}{2}$ to 2% of the original content of the nickel and copper in the raw ore. The fine ore is roasted in four Wedge furnaces, each being $22\frac{1}{2}$ ft. diameter.

SMEETING. The coarse ore is smelted in blast-furnaces and the fine in reverberatories. There are seven blast-furnaces; five are 50 by 204 in. inside at the tuyeres, 19 ft. high from the hearth to the charging plate, and are rated at 500 tons per day. One has a cross-section 48 by 255 in., and the remaining one 50 by 306 in. There are two tiers of water-jackets; the lower or tuyere-jackets are 8 ft., and the upper ones 6 ft. 4 in. high. In the smaller furnaces the blast is introduced through 32 tuyeres at a pressure of 22 to 35 oz. Each furnace smelts from 300 to 440 tons of ore per 24 hours. The charge consists of:

	Tons
Roasted ore	62.2
Raw Creighton mine ore.....	9.8
Raw Crean Hill mine ore.....	8.7
Coke	11.0

The Crean Hill ore is silicious and is used to flux the iron. From the furnace the molten products flow continuously into oval chrome-lined settlers; the matte, which has a specific gravity of 4.6 to 4.8, settles, while the slag with a specific gravity of 3.7 overflows continuously through a spout into 25-ton slag-pots and is hauled away to the dump. The matte is tapped from time to time into 7-ton ladles and transferred by rail to the converters. The operation is conducted so as to yield a matte containing 25% of copper-nickel, the ratio being 2.25 parts of nickel to 1 of copper. The average concentration during 1916 was 100 of ore to 22.7 of matte, the latter containing

*Abstract: Report of the Royal Ontario Nickel Commission, by F. H. Mason.

86% of the metal content of the charge. Of the total sulphur in the charge 44% is oxidized in the furnace. In the smelting operations at the Canadian Copper Co., it is necessary to handle large quantities of fine ore and flue-dust. Formerly this material was either briquetted, or sintered, and smelted in the blast-furnace, but this practice has given way to smelting in reverberatory furnaces. These furnaces are built on raised blocks of poured slag 11 ft. above the yard-level, so that tappings can be made directly into pots. Each furnace occupies an area of 23 ft. 6 in. by 116 ft. 9 in. outside the brick-work. At the fire-end the height of the arch above the hearth inside at the centre is 7 ft. 9 $\frac{3}{4}$ in. and 6 ft. 8 in. above the 'skim-line'. This height is maintained for 34 ft. from the outside of the fire-wall where the arch drops to 5 ft. 11 in. above the hearth and is continued at this height to the throat. The walls and roof are made of silica-brick and the hearth of tamped sand. The furnace is fed in an unusual way: A long trough extends down each side of the furnace. Each trough has openings in the bottom 2 ft. apart, which communicate by a side grate with 6-in. iron pipes; these pipes pass through holes drilled in the roof and allow the charge to slide down on the side walls, forming an almost continuous blanket. Small bottom-dump cars run on 24-in. tracks over the troughs and keep them full of ore. As there are no charging-doors to the furnace, and as the pipes are clayed into the roof, no air enters the furnace except what is purposely introduced at the fire-end, so an exceedingly even temperature can be maintained. The pipes form a continuous line of charging-holes which extend the entire length of the furnace. The charge on the side opposite the slag-door is fed all the way to the throat. On the slag side, it is fed only as far as the slag-door, as the cold air entering the furnace during skimming cools the wall from the skim-door to the throat. The furnace is fired with coal-dust introduced through five 5-in. pipes, one on the centre line of the furnace 5 ft. 2 in. above the hearth, the others on a horizontal line 3 ft. 3 in. apart. The coal used is of good quality, having a thermal value of 13,500 b.t.u. per pound. The charge consists of:

	%
Wedge calcine and flue-dust.....	64.0
Raw Creighton fine	2.0
Raw Crean Hill fine	21.7
Blast-furnace flue-dust	12.3
Coal burned	22.5

If necessary, sand is added as a flux. The skinning-door allows the slag to run off 14 $\frac{1}{2}$ in. above the hearth. The matte is tapped from time to time and sent to the converters.

The converters are 37 ft. 2 in. long by 10 ft. diam. outside, and turn on four head-rings 12 ft. diam. They are lined with magnesite-brick and have 44 tuyeres 1 $\frac{1}{4}$ in. diam. and 7 in. apart. Each converter has two spouts from which the products of combustion pass to the stack during the blow and the slag and matte are poured when the converter is lowered for that purpose. The charge consists of:

	Tons
Blast-furnace matte	380
Reverberatory-furnace matte	46
*Creighton green silicious ore.....	96
Scraps from ladles	25
Quartz	83

*This Creighton ore contains 70% silica, 0.6% nickel, and 0.5% copper, and is used primarily as a flux.

The air is introduced under a pressure of 10 $\frac{1}{2}$ lb., and each converter requires about 6500 cu. ft. of air per minute. In commencing the blow 70 tons of matte are poured into the converter and 7 tons of flux added. The blast is turned on and maintained for one-half to three-quarters of an hour. The slag is then poured off and more matte and flux added. This cycle of operations is continued until the full charge has been introduced. The length of the blow, the amount of slag removed, and the weight of the matte and flux added after each skim, are all dependent on the grade of the matte. The resulting converter-matte contains from 50 to 55% nickel, 25 to 30% copper, 20 to 21% sulphur, and 0.2 to 0.5% iron. It is cast into ingots and shipped to Bayonne, New Jersey, to be refined by the International Nickel Co. A refinery is being built at Port Colborne, Ontario, by the International Nickel Co. of Canada, a subsidiary of the International Nickel Company.

The practice at the plant of the Mond Nickel Co. is similar to that at the Canadian Copper Co., except that the fine is sintered in two Dwight-Lloyd mechanical roasters and smelted in a blast-furnace instead of in a reverberatory. The Mond company's ores contain less sulphur and more copper than those of the Canadian Copper Co., so it is possible to use a larger proportion of green ore in smelting, and, in the process of converting, the matte is carried to 82% nickel-copper and has been carried as high as 85%. The average analysis of the converter matte is: nickel 41%, copper 41%, sulphur 17%, iron 0.6%. The matte is refined at Clydach in South Wales.

The New Caledonian ores contain neither copper nor sulphur, and average 7 to 8% nickel. They are smelted in small blast-furnaces that have a daily capacity of 25 to 30 tons of ore. The charge consists of ore, limestone, gypsum, and coal or coke ground together, briquetted, and smelted with coke. The resulting matte contains 50 to 55% nickel, 25 to 30% iron, and 16 to 18% sulphur. Before the War this was shipped to a number of European points and to New Jersey. Now most of it finds its way to Bayonne. The European method of treatment was practically the same in all cases, and consisted of de-ferrating or bessemerizing in small converters, pulverizing and roasting the resulting matte free from sulphur, briquetting the calcine with farinaceous material, which serves as both a binder and a reducing agent, and heating together with charcoal in retorts at a bright red heat for 48 hours. The metal, which is generally in the shape of cubes or discs, according to the shape of the briquettes, is sifted to remove the charcoal, and polished ready for the market by rotating in a drum. It assays 99.25% nickel.

REFINING. Except the small amount obtained from New Caledonian ores and that obtained as a by-product in other metallurgical operations, the nickel of commerce is refined by one of three processes, namely, the Orford, the Mond, and the Hybinette. The Orford is the oldest process and is based on methods employed in England before the Sudbury ores were exploited (1886). It is based on the fact that if a matte consisting of sulphides of nickel, copper, and iron is melted with sodium sulphide, the product separates into two layers. The upper and more fusible layer is composed of double sulphides of copper, and sodium, and iron and sodium, with a little nickel sulphide, and the lower layer of nickel sulphide with small quantities of copper sulphide. In carrying out the process, the matte, as received from Sudbury, is fused with 60% of its weight of nitre-cake and sufficient powdered coke to reduce the nitre-cake to sulphide in a basic-lined open-hearth reverberatory-furnace. The mixture is allowed to remain in the furnace for four or five hours, and is poled frequently with green poles, which not only thoroughly mixes the sulphides, but, on account of the hydro-carbon gases given off, materially assists in reducing the nitre-cake to sulphide. When the operation is finished the mixed sulphides are cast into molds, the heavier nickel sulphide sinking to the bottom. If a very clean separation is required, the nickel sulphide is again treated with nitre-cake and coke. When the sulphides are solidified they are turned out of the molds and a blow by a hammer separates the nickel sulphide from the mixed copper-sodium and iron sulphides, which are called the 'tops.' The tops are leached with water, dissolving the sodium salts which are evaporated for further use. The residue, consisting of copper and iron sulphides and most of the gold and silver, is smelted and blown to blister, which is sold to copper refiners who recover the nickel content, usually about 24%. The bottoms, which still carry a small quantity of copper, are ground and roasted, with a little salt, in a reverberatory furnace. This converts the copper into soluble sulphate and chloride and the nickel into insoluble oxide. The leaching of the calcine gives a solution containing the copper and some platinum, palladium, and rhodium, which is treated by a secret process for the recovery of the precious metals. The nickel oxide residue is reduced to metal in a reverberatory-furnace fired by oil. The product generally contains 99% nickel, together with a little cobalt, iron, and some of the platinum group of metals. When a pure product is required this is refined electrolytically.

The Mond process of refining nickel-copper matte is unique among metallurgical processes. The matte is ground in ball-mills to pass 60-mesh, and roasted in straight-line double-deck calcining furnaces. The calcine, containing less than 2% sulphur, is leached with 10% sulphuric acid. This removes 70% of the copper and about 1% of the nickel. The residue, containing 51% copper and 21% nickel, is washed, dried on vacuum filters, and transferred to the reducing towers. The

latter are vertical towers built of 24 short-cylindrical sections to a height of 40 ft., each section contains a hollow shelf, which permits heating by producer-gas to 350°C. The leached calcine is introduced at the top, and as it descends is carried alternately from the centre to the periphery and from the periphery to the centre by rabbles attached to a central shaft. A current of water-gas ascending through the tower reduces the copper and nickel oxides to metal, and the ferric to the ferrous oxide. The reduced material is carried through a gas-tight conveyor to another tower of similar construction but with solid shelves. Here, as the material descends, it meets a current of carbon monoxide gas at a temperature ranging from 50 to 80°C., which converts the nickel into nickel carbonyl, a gaseous product, that is carried to the decomposer. After passing through the volatilizer the mixed metals are returned to the roaster and once again start their journey toward the volatilizer. This continuous round, which is carried on for 7 to 15 days, is necessary, because, after a part of the copper has gone into solution as sulphate, the nickel oxide forms a protective coating and prevents further solution of the copper oxide, while in the volatilizer, after part of the nickel has been removed, the copper stops further volatilization. The final residue, which contains metals of the platinum group together with rhodium, gold, and silver, is sold to precious-metal refiners. The decomposer is a cylindrical vessel containing a central tube with holes through which nickel carbonyl passes into the outer vessel. The tube is kept cool by an inner tube through which water circulates, thus preventing the dissociation of the nickel within the tube. The outer vessel is maintained at about 200°C., at which temperature the nickel carbonyl is decomposed into nickel and carbon monoxide. The carbon monoxide is returned to the volatilizer, where it volatilizes a fresh supply of nickel. The granules of nickel, formed by the decomposition of the carbonyl, are kept in continuous motion within the decomposer by means of a right and left-handed worm-conveyor which delivered the granules to a sifting-drum. The smaller granules are returned to the top of the decomposer and the larger ones removed for the market. This continuous movement prevents the granules from adhering to each other. The nickel deposits on the granules in concentric layers and thus they grow gradually. It requires about two months to produce a shot 1/4-inch in size, and six months for a 3/4 in. shot. The copper-sulphate solution formed by treating the roasted matte with 10% sulphuric acid contains 2 to 2 1/2% of nickel. The sulphates are separated by fractional crystallization.

The last process in commercial use of refining nickel-copper matte was invented by V. N. Hybinette and has been in use for many years at Kristiansand, Norway, for refining matte produced at Enje, Ringerike, and Stavanger. This process will be used by the British American Nickel Corporation at Sudbury or where they place their refinery. The bessemerized matte obtained from the smelters at Enje and Ringerike contains about 80%

of nickel-copper and averages 47% nickel and 33% copper, so, it will be seen, it is similar to the matte produced at Copper Cliff, Ontario. The matte, which is received in a granulated form, is roasted to remove the bulk of the sulphur and leached with a 10% solution of sulphuric acid. The residue is melted and cast into anodes 3 ft. by 3 ft. 6 in. by $\frac{1}{2}$ in. thick. The anodes contain about 65% nickel and 3 to 8% sulphur, the remainder being copper with a little iron. The nickel and the copper are deposited separately. The electrolyte used for the nickel deposition contains 45 gm. nickel and 3 to 5 mg. copper per litre, and is supplied by rubber tubes to the cathode diaphragms and kept in continual motion. After circulation the electrolyte contains 2 to 3 gm. copper per litre, and is then passed over waste anodes that precipitate the copper and re-supply nickel to the solution. The amount of waste anode during the electro-deposition of the nickel—about 30 to 40% of the original weight—is sufficient to re-vivify the exhausted solution from the nickel vats. These solutions are never thrown away, as the cementation of the copper purifies them sufficiently. Any fragment of waste anodes remaining after the cement copper has been cleaned off are crushed, roasted, leached with 10% sulphuric acid, and re-melted into new anodes. During the deposition the anodes are contained in a special canvas bag. The cathodes are made of iron plates rubbed with a thin wash of graphite and water, and are arranged in parallel; the voltage depends on the number of vats in use; three to four volts per vat being used, according to the current density, which is 8 to 10 amperes per square foot of cathode. The nickel deposition takes 10 days to complete, and the deposited nickel is about $\frac{1}{2}$ in. thick and weighs 20 to 30 lb. It has the usual corrugated warty appearance, but is dense, the warty or stalactitic growths being normal, and gives no trouble by short-circuiting. The plates are washed with weak acid and cut up and marketed without being melted. The precious metals become concentrated in the anode slime, which is melted into fresh anodes, and electrolyzed separately, the final slime being sold to refiners of precious metals. The copper is recovered similarly to the nickel, in a separate plant, but on sheet-copper anodes, and without bags around the insoluble lead cathodes. The current density is 10 amperes per square foot of cathode at two volts. The copper takes seven days to deposit, and the precious metals are obtained from the anode slime, as with the nickel.

METALLIC cerium is obtained by the electrolysis of the chloride or fluoride, and if alloyed with iron, it emits sparks when rubbed on a hard rough surface. This property has been utilized in the manufacture of gas lighters. An even better material for this purpose is made by submitting an alloy of aluminum, magnesium, and cerium to a current of hydrogen at a dull red heat. The alloy takes up some of the hydrogen, forming a hydride that sparks brilliantly when rubbed on a rough steel surface.

Minerals Separation Contracts

The 'Boston News Bureau' says:

Four different methods of assessing royalties in payment for use of flotation in the treatment of ores have been determined upon by the Minerals Separation company, which controls 50 patents in the United States.

The bases for these payments follow:

(1) Percentage of gross value of all metals recovered from total ore milled, irrespective of methods of treatment so long as flotation is used anywhere in the flow-sheet.

(2) Unitage, a fixed rate per unit (20 lb. per short ton) or per ounce of various metals recovered from total ore milled if flotation is used anywhere.

(3) Poundage, meaning fixed rates per pound or per ounce of various metals recovered from any material treated by flotation.

(4) Flat rate, or fixed rates per ton of copper ore milled, according to average daily tonnage of mill-feed.

Where complex ore occurs royalties shall be paid at regular rates applicable to all and each of the resultant products. The company limits the flat-rate schedule of royalty for copper to ores yielding copper concentrates which do not contain admixed metals in commercial quantities. Secondary values in commercial amounts must be paid for in additional royalty.

Applying to copper ores the schedule provides (1) for payment of $2\frac{1}{2}\%$ of gross value of total copper contained in all concentrates recovered with additional $2\frac{1}{2}\%$ payments on gross value of any other metals secured from concentrates and paid for by smelter; (2) 6c. per unit for total copper contained in all concentrates recovered together with $2\frac{1}{2}$ c. per ounce for all silver and 25c. per ounce for all gold recovered and paid for by smelter; (3) 1c. per pound for all copper contained in such concentrates or products, together with 5c. per ounce for silver and 50c. per ounce for gold, this applying only to metals recovered by flotation; (4) the flat basis provides for the payment of 12c. per ton of ore treated up to 4000 tons daily, 10c. per ton for the next 2000 tons, and 9c. per ton for the next 4000 tons treated daily. The flat basis of payment applies to the entire tonnage of copper ore treated, provided any portion has been handled by flotation, except that copper ores smelted direct without any previous process shall be exempt from royalty payment.

Where the unit basis shall be adopted by a zinc company securing a license, additional payments shall be made at the rate of 2c. per unit for lead, 6c. per unit for copper, 1c. per ounce for silver, and 25c. per ounce for gold contents. Payment where flotation alone is used calls for additional payments on zinc ores of 0.3c. per pound for all lead contents, 1c. per pound for copper, 5c. for silver, and 50c. per ounce for gold.

The contract secured by the Anaconda and Inspiration companies was adopted before the present schedule was determined. This calls for 4c. per ton of ore.

Ontario Gold and Silver in 1917

By THOMAS W. GIBSON

*Among the metals, the adverse effects of the War fell principally upon gold. In times such as the present, when commodity prices have greatly increased and labor is scarce, the intrinsic value of gold is lowered, since any given number of ounces will only be taken in exchange for a reduced quantity of goods or work. Hence, a gold mine, while nominally receiving exactly the same prices as before for its product, suffers by the increased cost of labor and supplies. Other metals have advanced in price, and consequently the producers, although their products cost more, are enabled to recover this additional cost, and in some cases much more, from the consumers. The gold mines of the Province produced about \$8,750,000 in gold, as compared with \$10,339,259 in 1916. The largest mine, Hollinger Consolidated, ceased paying dividends, but remained in operation, producing about \$4,450,000 in gold. The mill of the Dome Mines closed in November, the low-grade ore not being able to stand the heightened cost of production. All the other Porcupine companies continued working, namely: McIntyre-Porcupine, Porcupine Crown, Porcupine V.N.T., and Schumacher. The Dome output for the nine months was \$1,219,000; that of the McIntyre-Porcupine for the full year, about \$1,600,000. The total output of the Porcupine camp was in the neighborhood of \$8,300,000. The history of the Porcupine field so far has been very satisfactory, and there is no doubt that, when conditions return to the normal, good profits will again be realized.

Next to Porcupine, Kirkland Lake is the most active and advanced gold district. There are now two mines producing bullion, Tough-Oakes and Teck-Hughes. Properties which are more or less rapidly being put into condition for production are: Lake Shore, Kirkland Lake, Wright-Hargreaves, and some others. Mills in operation and under actual construction will have a capacity of 530 tons of ore daily. It is being demonstrated that gold occurs in important quantities in many and widely separated areas of northern Ontario. Among the younger districts of promise are: Munro township, West Shining Tree, Boston Creek, Bourke's Siding, Kirkland-Tashota, and Powell township. The Croesus mine, in Munro, which showed quartz of remarkable richness, and whose plant was destroyed by the disastrous forest fires of 1916, is again in operation. The shaft is down to a depth of 400 ft., and the continuation of the vein, which had faulted, is being looked for. The Anderson find at Bourke's, and the Murray-Mogridge property at Wolfe Lake are showing well. At Boston Creek, the Miller Independence and Patricia (formerly Boston-Hollinger) are the principal prospects. West Shining Tree con-

times to excite hopes by samples showing much visible gold. Little, if anything, is at present being done at Tashota, the Tash-Orn Co. having got into difficulties and ceased operations. At the old St. Anthony mine, Sturgeon lake, work has been going on for some time under the new owners, but production has not yet begun. The

MAP OF A PART OF ONTARIO

Canadian Exploration Co. has closed the Long Lake mine, near Naughton, on the Sauli Branch of the C. P. R. It is a poor year that does not yield one or more new gold camps in northern Ontario. The latest was a find made at the head-waters of Lightning river, last autumn, by a prospector named Cochenour. The vein has been sampled, and the assay values run from \$20 per ton

*Abstract: Can. Min. Inst. Bull., Jan. 1918.

upward. The geology is said to resemble that of Porcupine, and a considerable number of mining claims have already been staked.

The silver output was practically equal to that of 1916, namely, 20,000,000 oz., but owing to the higher prices for silver, the money value was considerably greater, that is, nearly \$16,000,000 in all. The Cobalt mines are still the sole source of silver. The Nipissing mine, so long pre-eminent, was last year surpassed in production by the Mining Corporation of Canada, which operates the Townsite-City and Cobalt Lake mines. Beneath the streets and buildings of Cobalt, the rich veins of the Townsite-City yield an abundance of high-grade ore. Last year the Mining Corporation's production amounted to about 5,000,000 oz., or say, one-quarter of the total output of the camp. Nipissing mine is still producing much silver; last year the yield was about 3,750,000 oz., nearly equal to that for 1916. The dividend payments by this company have now reached more than \$17,000,000. Kerr Lake also continues to produce freely, practically equaling the 1916 record with 2,500,000 oz.; Coniagas yielded about 1,300,000 oz.; McKinley-Darragh-Savage about 1,000,000 oz.; O'Brien and Temiskaming did fairly well. The last-named mine has not found, at the lower diabase contact, the hoped for bodies of bonanza ore. Some ore was obtained, but two separate reports made to the shareholders during the year do not hold out hopes of a large future production. La Rose, Crown Reserve, Hudson Bay, Beaver, Buffalo, Trethewey, and other well-known mines produced bullion, but on a smaller scale than in former years. Interest in Gowganda camp was revived by the rich high-grade vein found in the Miller-Lake O'Brien mine, and development on nearby properties has been undertaken. On the whole, the mines of Cobalt met the situation of 1917 in good style, and were able to market a large production at the prevailing high prices. The reported negotiations of the British and United States governments, to purchase 100,000,000 oz. of silver, will mean much to Cobalt if carried out, especially if the price is raised from 85 cents to between 90 cents and \$1, as is now suggested.

The flotation process of concentration has been widely adopted in Cobalt, and will serve to prolong the life of the camp. There is some apprehension that the Minerals Separation company will endeavor to exact excessive royalties. The Cobalt mine-owners believe that the patents are of German ownership, and it is understood that the Dominion government has undertaken to investigate. The 1917 silver find was in the township of Corkill, some distance south-east of the Gowganda deposits. The discoverer was Hugh Miller Kell, and the ore is said to be rich, though development has not yet proceeded far.

One satisfactory feature of mining in Ontario is the willingness of individuals and companies, that have made good in one area or mineral district, to try their fortune in another. A notable instance of this is the Timmins group, who, after successful operations in La Rose silver, took up the Hollinger gold claims and made another big mine there. Other examples are: Crown Reserve Mines,

which put part of the profits made in the mine at Cobalt into the Porcupine Crown gold mine, and now Newray; Buffalo Mines, which is operating the Teck-Hughes in Kirkland Lake, and the Beaver, now developing the Lake Shore claims at the same place. Coniagas, too, has gold claims under development at Porcupine.

Flotation in Michigan

While there is hope that the flotation process of the Minerals Separation Co. may be applicable to the amygdaloid lodes of the Michigan copper country, there really is not much reason for expecting that any large sums will be realized from its practical operation on such sand. Long continued experiments by the Calumet & Hecla interests on their conglomerate sand showed successful results, but on the Osceola sand no such results were secured. Ultimately the Calumet & Hecla will treat all of its conglomerate slimes by the flotation process. This includes the slime from the current mill operation as well as the slime from the sand-pile from the lake, even the slime treated by leaching. At the White Pine property there are two classifications of tailing that will be treated by the flotation process. One is the regular slime and the other a grade of light and flaky copper that ordinarily is not saved, but that is caught by the flotation scheme. They operated a 50-ton plant for an experimental period and now are handling practically all of the tailing with a 600-ton plant, most of which is in operation at this writing. No other mines in this district have experimented with the process and while some of the concentration experts are planning on trying the scheme, they are frankly dubious as to its success.—Boston News Bureau.

AN ITALIAN geologist, E. Crivelli, has recently made a notable contribution to the study of the magmatic or so-called igneous origin of petroleum, based in part upon observations of the intimate relationship between the mineral and the oil deposits of Peru. It is shown how the oil probably may have been formed by migration of hydro-carbon derivatives through fissures from deeply seated magmas, and much new light is thrown upon the volatile metal-carbon compounds, as, for example, the carbonyls and acetylides of nickel and iron. He also shows that the peculiar deposits of so-called coal in the high Andean valleys may have resulted from reactions between such magmatic emanations as hydrogen, methane, ethane, carbon monoxide, and others.

EXPERIMENTS to discriminate the colloid minerals have recently been made by Cyril W. Greenland of Columbia University. He tested staining with dyes, and it was concluded that the taking up of a dye by an amorphous mineral substance may be due to the penetration of the liquid through capillarity in cracks rather than to adsorption, and that no general method for proving the gel-nature of a mineral can be based on our present knowledge.

REVIEW OF MINING

NEW YORK

FUEL SITUATION.—STOCKS.—TOLUOL MANUFACTURE.—FREIGHT CONGESTION.

The coal situation still claims first attention in spite of optimistic forecasts by the Fuel Commissioner of an early return to normal industrial conditions and 'fair and warmer' prognostications from the weather bureau, which failed to materialize. The temperature is again of the zero variety, coal arrivals are of spasmodic occurrence, and the prospect of the full 12 days vacation during the present month is more than probable. There has been a ready acceptance of the conditions invoked by the authorities and no question as to their necessity. The feeling that persists is that prevention would have been better than cure. Personal loss and discomfort has been considerable, and hundreds of apartment houses in the city have been without heat for the majority of the time. One householder is reported to have temporarily weathered the crisis by donning his furnace clothes, taking a job as driver of a coal wagon, selling the first load to his wife, and returning with his resignation. A sidelight in the coal situation is seen in the fact that the New York State breweries consume about 2400 tons of coal per day. The sanity of diverting this amount of fuel to the more essential industries could not have been questioned.

The majority of stocks, including mining shares, have shown a marked appreciation in value during the week. This has been variously attributed to the failure of peace negotiations between Germany and Russia, the strike in Germany, and optimistic rumors with reference to the possibilities of a general peace in the near future. Liberty Bonds, however, all reached new low records. This was possibly due to liquidation in preparation for the next loan which, it is rumored, may bear interest at 4½%. The British \$100,000,000 loan of one-year 5½% notes matured on February 1. Of this amount only about \$1,000,000 was converted into 20-year bonds. The payment for the balance was met by cash to the amount of \$40,000,000 from an \$80,000,000 yen loan to Great Britain from Japan and available in New York, \$10,000,000 from the same source in consideration of 300 lakhs of rupees received from the British government, and the balance, about \$50,000,000 from British funds in this country.

The urgent need of toluol for the manufacture of explosives has led to drastic action on the part of the Government to increase the supply. The gas plants in New York are to be equipped with the necessary apparatus, which is to be paid for out of government funds. The aim will be to extract the maximum amount of toluol and to make a monetary compensation to the gas companies. The British thermal unit of measurement will replace the present candle-power unit. The change to by-product ovens has been under consideration for some time, but the companies were unwilling to go to the expense involved without some guarantee that the outlay would be justified by the returns and that the demand for the by-product would persist long enough for them to be recompensed. The difficulty in arriving at any satisfactory settlement on this basis led to the Government taking the initiative, installing the necessary plant, and paying the companies a

satisfactory price for the by-product. It has been pointed out that, as only 20% of the gas is used for illuminating purposes, the British thermal unit is the more reasonable standard to adopt; and an equivalent of 650 B.t.u. per candle-power has been fixed.

Further suggestions for the alleviation of freighting congestion in and around the city are being made. One scheme provides for tunnel roadway under the Hudson river to connect New York with Jersey City. Another involves the building of a traffic bridge across the river to connect these two points. The tunnel scheme is to be discussed at a conference of governors, mayors, and congressmen; and it seems probable that some steps will be taken to put the plan into execution. At present 30% of the freighting is done over the lines of the New York Central railroad, the balance being floated across the Hudson. During the past 25 years about \$700,000,000 has been expended in enlarging and improving terminal passenger stations in the city and affording other facilities for travelers. Nothing has been done to improve freighting conditions.

The Interborough Rapid Transit Co., operating the subway and elevated lines, reports an increase in the number of passengers carried during the latter six months of the year of 9,475,402 as compared with the corresponding period in 1912. This makes a total of 374,653,402 for the half year. The traveling millions view the company's success along these lines with apprehension of increased discomforts.

There were 1023 elections to membership of the Institute of Mining Engineers during the past year, bringing the number of members to 6528. This is an achievement for which due recognition must be paid to the work of the Committee on Increase of Membership. The forthcoming annual New York meeting, although shorn of a proportion of its usual social attractions, promises to be a still greater success in other directions. Over 50 papers are to be presented and dealing with a variety of subjects. The February bulletin contains the names of nearly 200 members of the Institute who are now in Military Service.

An interesting feature of the quarterly report of the New Jersey Zinc Co. is the mention of the profit-sharing distribution to employees, which amounted to \$450,000 for the three months ended December 31.

EAGLE PASS, TEXAS

METAL IMPORTATIONS FROM MEXICO

It is shown by the records of the United States custom offices at the different border ports of entry that there was a large increase in the quantity and value of importations from Mexico into this country for the year 1917 over those of the preceding year. In fact, it was one of the best years from a trade standpoint that has been experienced since the revolutionary period began in Mexico, more than seven years ago. While the official statement of importations and exportations through the different ports of entry has not yet been compiled, it is known that the showing is gratifying to the trade interests. The total value of the exports through El Paso for 1917 was \$5,660,709, which was an increase of \$1,497,970 over the value for 1916. The proportion of increase at Eagle Pass and Laredo greatly

exceeded that at El Paso, owing to the fact that the railroads leading into Mexico from the two former towns have been open for traffic almost continuously during the past several months, while the line running south from El Paso has been out of service at long intervals on account of the depredations of revolutionists and bandits.

The metal and ore importations through El Paso during the year 1917 showed a good increase. The figures of these importations through Laredo are not as yet available, but it is stated that they amounted to much more than those for the El Paso custom office. The most notable gain was in copper. There was a falling off in the importations of lead and zinc. The figures for El Paso for the year may be taken as a basis for the other border ports of entry.

The value of the total imports for 1917 amounted to \$2,804,634, a decrease of \$155,164. Gold-ore importations for the year amounted to \$3599, a decrease of \$32,715; gold bullion imported was \$7721, a decrease of \$72,720; silver ore increased from \$738,262 to \$1,249,837, surpassing 1916 by \$511,575; silver bullion, on the other hand, dropped from \$566,730 to \$165,278, a decrease of \$401,452. The total value of copper ore imported was \$93,683 for 1917, against \$86,266 for 1916, a gain of \$7417; lumber importations amounted to \$136,130 against \$56,506 for 1916, an increase of \$79,624. Lead fell off \$44,577, total importations for 1917 having been \$239,504 as against \$284,081 for 1916. Zinc receipts show a still worse slump, the total decrease for 1917 having been \$148,391, the total ore imported for 1917 having a value of only \$342,932, while that of 1916 reached \$761,323.

LEADVILLE, COLORADO

MOLYBDENUM AND MANGANESE MINING.

Developments in the new molybdenite district at Climax, north of Leadville, are being rushed ahead. Three big companies, the American Metal Co., the Molybdenum Products Co., and the Pingrey Mines Co., are actively opening the ore-reserves in their properties and erecting concentration plants. At Buffher, a mile below Climax, in Summit county, the Molybdenum Products Co. is constructing a 250-ton mill in which a secret process for the treatment of molybdenite will be used. The process, which was perfected last year after a long period of experimenting, is reported to be highly successful. The ore averages 1% molybdenum. An aerial tramway nearly two miles long is being erected from the mill to the company mines on Bartlett mountain. At Climax, the American Metal Co. has almost completed the new 250-ton mill that has been under construction for several months. Work on the mill was started last August under the direction of J. H. White, who is superintendent for the company. Boarding-house, bunk-houses, shops, offices, and other buildings have been erected near the mill and a boarding-house and bunk-house have been built at the mine a mile above on Bartlett mountain. A tram has been completed to carry the ore to the mill. The American Metal Co. controls the largest tract of molybdenite ground in the district, and through an 800-ft. adit and numerous cross-cuts, has blocked out an immense tonnage. The ore averages 1% molybdenum. The mill is equipped with Blake crushers, ball-mills, Callow and Janney flotation machines, and a Portland filter. The company plans to put the mill in operation and begin shipping concentrate during the present month. For several weeks the Pingrey Mines Co. has been engaged in opening the orebodies in the Black Metal group of claims, also on Bartlett mountain. O. A. King, the manager, states that a large tonnage has been blocked out and a number of shipments have been made to the Leadville district mill where a satisfactory concentrate was made. Plans are now being completed for the erection of a 500-ton mill near the company's ground at Climax.

The Denver Mining & Milling Co. has just completed overhauling and improving its mill at Wortman and will start milling during the month. A large body of lead-zinc sulphide has been blocked out in the old Wortman property; a milling process has been perfected and the necessary machinery erected.—Three hundred men are now employed in the district comprising Wortman, Climax, and Buffher, where a year ago there was none. The operations of the large molybdenum companies have been the direct cause of the present prosperity and have indirectly brought about the opening of other smaller properties. It is estimated that 1000 men will be working in this district during the summer.—Lessees operating through the Hibsche shaft on the Wolcott ground in the Down Town district have discovered a large body of manganese ore, averaging 31% metal. The first shipment will be sent to the Colorado Fuel & Iron Works at Pueblo this week. The orebody is the extension of one of the big deposits recently uncovered in the Northern property, which is one of the heaviest producers of manganese in the district.—A company of lessees, headed by Harry McKeen, has just discovered a strong ore-shoot on the 1000-ft. level of the Evelyn property in Graham park. The ore is a high-grade silver sulphide and is believed to be one of the rich veins that was formerly developed in the Mahala property adjoining. A steady tonnage is being produced.—John Cortellini and associates have taken a lease on the old Sunday property on Ball mountain and are extracting a small tonnage of rich gold-lead ore. Work is being carried on through the Sunday shaft. The ore-shoot is strong and continuous and shows promise of developing into an important deposit.—The Dold Mining Co., operating through the Northern shaft in the Down Town district, is now completing plans for re-opening the Newell shaft. A large tract of ground north of the Newell and extending into Poverty Flats has just been secured under lease, and development from the Northern has discovered another large deposit of high-grade manganese. The situation of the Newell shaft makes it the logical hoisting centre for this new area and it will be equipped with an efficient plant. The Denver & Rio Grande has consented to repair the old siding to the Coronado and Midas and extend it to the Penrose shaft of the Down Town company. This will afford direct haulage for the Newell, which is within 50 ft. of the right-of-way. The Down Town Mines Co. has been seriously handicapped in ore-production during the past month because of the inability of the Colorado & Southern to handle the output. The small narrow-gauge engines are not equal to the task of switching 50 and 60-ton cars in stormy weather and the Penrose has been tied up for several days at a time.

PLATEVILLE, WISCONSIN

BAD WEATHER CONDITIONS.—CAR SHORTAGE.—OUTPUT.

Zinc operators of the Wisconsin field began the current year under unsatisfactory market conditions, but with the hope that this drawback might be modified by heavy outputting. The stringency in the labor market had been overcome and the mines and plants were efficiently organized for a strong recovery of ore; unfortunately, however, a number of contingencies arose to defeat this effort. A scarcity of cars, made more manifest under the orders of the war board, existed all the month; about mid-month the field was visited by a howling blizzard that buried roads, plants, and railway tracks, bottling up the entire field most securely for a whole week, and on top of this came orders from the Washington administration for a five-day shut-down because of lack of fuel; this was religiously observed by every mining company. All the strenuous labor of digging out was nullified by a fourth severe snowstorm during the latter part of the month. This swept the field for three days, but the railway companies were better equipped to meet this last onslaught of the elements and less running time

was lost. Heavy snows were accompanied by extremely low temperatures and mill reservoirs and frozen intakes crippled many mining plants, interrupting working schedules. Power plants were shut-down through lack of fuel and patrons suffered until this deficiency was remedied. Operators faced the distressing situations gamely and working forces were treated with generosity in the payment of wages. The showing at the end of the month, both from the standpoint of production and deliveries, was better than expected and a reserve, estimated at more than 6000 tons of zinc concentrate, was carried over as well. Prices remained stationary all the month, the top grades calling for \$62 per ton base with the range down to \$52 on medium and second-grade ore. Refinery product was in better demand than other grades and sharp discrimination was shown in the offerings that applied to low-grade output with the result that shipments in this particular were greatly restricted and much low-grade ore was carried over. Independent low-grade producers, compelled to accept open market quotations, reduced working forces and in several instances suspended operations entirely for the time being. Unless immediate relief is afforded through advances in the price of zinc ore, it appears more than probable that little effort will be made to resume operations much before the return of spring weather among this class of mines.

The situation in the lead ore branch of the mining industry was much more encouraging, for prices advanced steadily all through the month until offerings reached \$85 per ton for 80% ore. Producers have steadfastly maintained that no sales should be made below \$90 per ton, and to this resolve they have been true, as shipments for the month will show.

Shippers of pyrite were encouraged to believe, through Washington reports that indicated the possibility of sulphuric acid supplies being commandeered, that better conditions would be ushered into this branch of the industry. Several of the larger refineries who carry a large reserve entered into long-term contracts just prior to the War and these have been at a great disadvantage on account of flat rates that afford little profit under the increased costs of supplies and labor. Much dissatisfaction exists and contracts are observed under a strict interpretation of the wording of such agreements, with the result that shipments are restricted and a reserve is held on in excess of 5000 tons.

Deliveries of zinc ore, lead ore, and pyrite, were made for January to refiners and smelters by districts as here shown:

District:	Zinc, lb.	Lead, lb.	Pyrite, lb.
Benton	16,828,000	206,000	1,716,000
Miffin	4,948,000	80,000
Galena	1,582,000
Linden	786,000	1,200,000
Highland	720,000
Hazel Green	608,000
Platteville	398,000
Shullsburg	352,000
Dodgeville	252,000
Cuba City	1,840,000
Total	26,474,000	286,000	4,756,000

Shipments from refining plants, in the field, January 1 to 26 inclusive, were made as follows:

	Lb.
Mineral Point Zinc Co.....	5,846,000
Wisconsin Zinc Co.....	2,854,000
National Separator Works.....	2,432,000
Linden Zinc Co.....	446,000
Benton Roasters Co.....	338,000
Total	11,916,000

The gross recovery of mine run for the month amounted to 13,928 short tons; net deliveries to smelters 9274 tons; a poor showing when compared with a similar period in 1917.

Sales and distributions were made to buyers as reported: Mineral Point Zinc Co., 4427 tons; Wisconsin Zinc Co., 3123 tons; National Separators, 2992 tons; Grasselli Chemical Co., 2942 tons; Linden Zinc Co., 922 tons; American Metal Co., 828 tons; Illinois Zinc Co., 738 tons; American Zinc Co., 466 tons; Benton Roasters Co., 175 tons; Matthieson & Hegeler Zinc Co., 160 tons; American Steel & Wire Co., 100 tons; Lanyon Zinc Co., 76 tons.

MAMMOTH, UTAH

TINTIC STANDARD.—PLUTUS.—CHIEF CON.—TINTIC DRAIN TUNNEL.—KNIGHT DRAIN TUNNEL.

Shipments of ore from the mines of the Tintic district during the month of January totaled 671 carloads, estimated at 30,000 tons in weight and \$900,000 in value. This production is compared with 709 cars in December, 896 cars in November, and 676 cars in October. The shipments in January 1917 amounted to 802 cars, showing a decrease this year of 125 cars; this is due to the fact that a year ago there were no restrictions by the smelters.—The present development on the 1260-ft. level of the Tintic Standard property has reached an interesting stage. Lately a drift was sent out 200 ft. to the east of the new shaft which cut ore. To the north of the shaft on the 1260-ft. level a drift has followed the main ore-channel for a distance of 100 ft. Here it takes half a dozen sets to span the face of the ore opened to date, and most of this breast is shipping quality. Some high-grade ore has been opened from the 340-ft. drift that connects the new shaft with the old stope on the 1260-ft. level. To the north and about half-way between the shaft and the stope some ore was struck, carrying 25% copper and 200 to 300 oz. of silver. The orebody is 40 ft. wide.—Four headings are now being driven into the big body of quartz, recently uncovered in that part of the Plutus ground which is being developed through the Victoria property. It will be remembered that a drift was run into the Plutus from the 1200-ft. level of the Victoria and, while the work has for some time been conducted under the most favorable conditions, the showing has never been as good as it is at this time. That the ore will be found in this quartz is the opinion of Cecil Fitch of the Chief Consolidated and, in order that no time shall be lost in bringing the Plutus into the productive stage, drifts are being driven in two directions and at the same time sinking and raising is in progress. Officials of the Chief Con. company have for several years been confident that one or more important ore-zones traverse the Plutus holdings and disclosures of the past year, particularly the finding of this body of quartz, have given them even greater confidence in the ground adjoining their own mine.—During the past year the Chief Con. did 15,430 ft. of development, including drifts 13,592 ft., raises 1626 ft., and winzes 212 ft. In addition considerable development was done at the Pinion Peak, or Homansville, section of the Chief's holdings, as well as extensive work on the Plutus company's ground. The total shipments from the mine amounted to 59,950 dry tons, which yielded, after payment of smelting, transportation, and sampling, \$1,554,714. The metal contents were: gold 9175 oz., silver 1,534,907 oz., lead 10,780,540 lb., and zinc 600,236 lb. The average gross value of ore was \$40.12 per ton and the average net value \$25.93. The net profit was \$427,637.24.—A. L. Hartley and J. M. McShane, both of Silver City, have sold the Betty Green and the Look Out claims to the Tintic Drain Tunnel Co. and Mr. Hartley also has conveyed to the same company the Josephite, Maid of Erin, Daisy, Summit, Grand View, Independence, May Flower, Ophir, Garden City, and Goshen claims. A part of this mineral ground will be

cut by the new drain tunnel and the remainder is in close proximity to the proposed line of the tunnel.—The Knight Drain Tunnel Co. is being hindered in its operations by delay in receipt of a set of transformers that were ordered several months ago. Work has reached a point where the electrical power is badly needed.—In an action filed in the Federal court recently, the Utah Consolidated Mining Co. seeks an injunction against the Tintic Mining & Development Co. restraining the latter from taking ore from the property of the plaintiff, situated in the Eureka district, and demanding an accounting for ore alleged to have been extracted. It is claimed that the Tintic company has extended the workings from its own mines into those of the plaintiff, and that ore to the value of \$300,000 has been extracted therefrom.—Work at the Utah Consolidated is progressing favorably. The copper ore it is now mining is low-grade and with the higher operating costs due to wage advances and high prices for supplies this ore will not yield a large profit on a 23c. metal-market. As the development in the lead area of its property is understood to have been satisfactory, however, it would seem that the greater portion of its profit in future will accrue from shipments of lead ore.

HOUGHTON, MICHIGAN

QUINCY.—CALUMET & HECLA.—WHITE PINE.—SENECA.—MICHIGAN.

The No. 2 shaft at the Quincy is hoisting copper ore from a depth of 7800 ft. One day this week when the miners started for this depth the thermometer stood at 28° below zero, with an 80-mile blizzard right from the Canadian shore coming across Lake Superior. When these miners reached their working places the temperature was so high that they worked stripped to the skin and the sweat ran off their healthy bodies. The "warm" mines are popular here in the winter time. Quincy now has under construction at the Nordberg shops, at Milwaukee, a hoisting plant that will carry copper ore from a depth of 10,000 ft. This is surpassed by few plants in the world as far as one long continuous haul is concerned. Ten years ago, when it was suggested that the time would come when copper ore could profitably be mined from a depth of two miles underground, it was considered preposterous. The writer remembers when one mile was considered out of all reason. Then came the Red Jacket shaft of the Calumet & Hecla and the Tamarack No. 5, both perpendicular shafts that went down a mile. These perpendicular shafts today are beating all records for speed in handling tonnages; and at the bottom of the vertical shaft at the Calumet & Hecla there is another hoisting plant, practically a duplicate of the surface plant, that handles tonnages from still greater distance on the dip of the vein.—The contract for the new Quincy hoist was let last spring and is to be delivered next summer. It will replace the present hoisting plant at No. 2 shaft, and the plant at the latter then will be removed to the Mesnard shaft No. 8, which is being gradually sunk deeper though already up to the capacity of the shaft hoist operating there. The hoist in use at Mesnard will go to the Pontiac, which branch of the Quincy has not been operating since the strike.

The Calumet & Hecla is operating only two shafts on the Tamarack property, No. 5 and No. 3, the latter formerly known as the North Tamarack. Nothing but conglomerate ore is coming from these shafts. Plans for greater economies in the matter of tramping and hoisting and the elimination of long hauls are being planned to handle this tonnage.—The recent fire damage is being repaired rapidly and shaft-sinking at the Seneca will start soon. The frame construction work is already well advanced.—The vertical No. 2 shaft at White Pine is getting into mineralized zone. The ore tonnage last month was 20,000, a substantial increase over previous records.

TONOPAH, NEVADA

TONOPAH MINING.—TONOPAH EXTENSION.—TONOPAH BELMONT.—WEST END.—CASH BOY.

At the Silver Top shaft of the Tonopah Mining Co. 31 ft. of development has been done and 56 ft. at the Sandgrass. Stopping on the Beta Fault vein on the 540-ft. level continues in good ore. On the 600-ft. level of the Mizpah stopping is being advanced on a 4-ft. face on the Mizpah vein. On the 1140-ft. level the Upper Sandgrass vein is 7 ft. wide. The shipments to the Millers plant amounted to 3250 tons.—The Tonopah Extension Mining Co. milled 9058 tons of ore during December, resulting in a net profit of \$18,000, which shows a decided increase over the net earnings of the preceding three months. At the No. 2 shaft 64 ft. of development has been done and 151 ft. at the Victor. At the No. 2 shaft on the \$50-ft. level raise No. 815 made a connection with the stope above. On the 1260-ft. level raise No. 469 shows a 3-ft. face of ore. On the 1350-ft. level raise No. 573 was advanced 17 ft. on a 3-ft. face of ore. The intermediate drift from winze No. 1501 on the 1540-ft. level of the Victor continues on a 5-ft. face of ore. On the 1680-ft. level west drift No. 1600 advanced 28 ft. on a 2-ft. face of ore, while east drift No. 1601 advanced 24 ft. on a face of equal size. West drift 1602 on the O.K. vein shows a 5-ft. face of ore. The foot-wall branch of the Merger vein, called the Victor vein, is being developed by drifts to the east and west. The production last week was 2380 tons.—On the 700-ft. level of the Tonopah Belmont Development Co. east drift No. 721 on the Shoestring vein shows 1½ ft. of good ore. Raise No. 19 on the 800-ft. level shows 6 ft. of good ore on the South vein, while raise No. 20 on the same vein has a 6-ft. face of good ore. West drift No. 9026 on the Occidental vein shows a 3-ft. face of medium-grade ore. On the 1100-ft. level east drift No. 1142 on the Western vein shows a 2-ft. face of medium-grade ore. Last week's production was 2557 tons.—The West End Consolidated Mining Co. declared a dividend of 10c. per share payable March 1, the books closing February 16. The amount of the dividend is \$178,849, making the total dividend to date \$994,243. The West End mill shipped 32 bars of bullion valued at \$64,000. At the Ohio winze No. 534 is progressing in low-grade ore, and drift No. 539 shows a full face of low-grade ore. On the 555-ft. level cross-cut No. 3 has been discontinued and raise No. 7 has been started to develop the vein. Stope No. 3 continues to produce good ore. Cross-cut No. 601, which is the new level started from raise No. 814, shows a face of fair ore. At the West End cross-cut No. 809 is in low-grade ore. The output last week was 1140 tons.

The MacNamara Mining Co. shipped 10,395 oz. of bullion valued at \$11,434. West cross-cut No. 700 advanced 58 ft. The output last week was 704 tons.—The recent strike made in the Cash Boy continues to show good ore on further development. The vein was cut in the south cross-cut from the winze on the 1600-ft. level. The vein has an easterly and westerly strike and a dip to the north, which coincides with the strike and dip of the veins in the Victor section of the Tonopah Extension Mining Co. A drift to the west has been started showing 9 ft. of ore assaying \$77 per ton. The east drift shows a full face of ore averaging \$43 per ton. The production last week was 165 tons.—On the 2nd level of the Wandering Boy shaft of the Jim Butler Tonopah Mining Co. raise No. 372 made a connection and work has been resumed in west drift No. 370. At the Desert Queen shaft raise No. 657 cut the South vein exposing 3 ft. of ore. The production last week was 406 tons.—An intermediate drift has been started from raise No. 815 at the Monarch Pittsburgh Mining Co. The face of the drift shows 3 ft. of quartz.—The miscellaneous production was 82 tons, making the week's production at Tonopah 10,738 tons with a gross value of \$182,546.

THE MINING SUMMARY

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—Another strike of good copper ore has been made at the Gold Ridge at Dos Cabezas. H. C. Kimball has left for California to negotiate for the new concentrating plant the company expects to erect shortly. The first unit will be 100 tons per day. There are two veins on this property each averaging 5 ft. and assaying 2.76% copper, \$3 gold, 13 oz. silver, and 11% lead.—A cyanide-mill of 100 tons capacity is being erected by A. Y. Smith to treat the tailing of the Commonwealth mine, which closed-down last fall. There is sufficient tailing to operate the mill for two years. The Middlemarch Mining Co., seven miles west of Pearce, has recently completed a new flotation plant. The Central Butte company is pushing development.

Bisbee, February 2.

GILA COUNTY

(Special Correspondence.)—A strike of ore carrying 28% lead besides gold and silver has been made by the Ray Silver-Lead Co., at Ray.

Ray, February 1.

MOHAVE COUNTY

(Special Correspondence.)—The station on the 250-ft. level of the Leviathan mine has been timbered and cross-cutting toward the Copper Wonder claim to the west is under way.—The Tom Reed Gold Mines Co. contemplates the further development of the Gray Eagle vein by 250 ft. of cross-cutting and 500 ft. of driving at the 535-ft. level of the Aztec mine. All ore from the Gray Eagle will then be trammed to the Aztec shaft and sent to the mill by aerial tramway.—Mr. Goldsworthy, the superintendent, announced that the cross-cut on the 550-ft. level of the United Northern has cut what appears to be the true orebody.

Kingman, February 4.

PIMA COUNTY

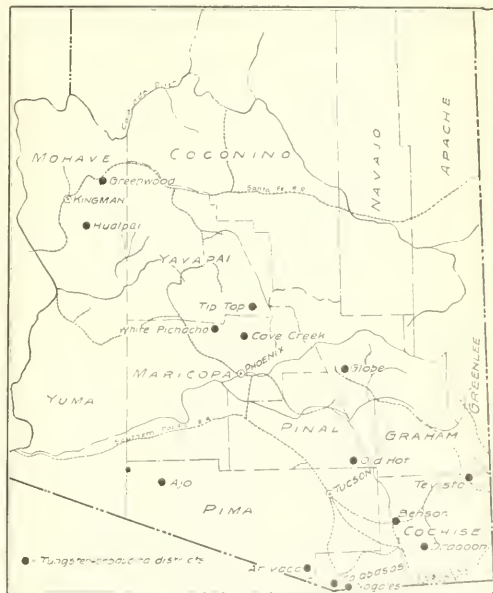

(Special Correspondence.)—A Bureau of Mines for Pima county has been formed and is to be under the jurisdiction of the Tucson Chamber of Commerce. The board of directors comprises most of the prominent and representative mining men from the operating districts of Pima county.—The Mineral Hill Consolidated, one of the oldest properties in the San Xavier district, has ceased shipping and has turned all energies toward development. The main shaft is down 500 ft. The ore that is being blocked-out assays 4% copper. A new duplex electrical pump capable of handling 250 gal. per minute is being placed; the power will be supplied by a 75-hp. semi-Diesel Y-type engine and 50-kw. generator.—Considerable work has been done on the Wakefield-Lambing group of claims, recently acquired by the Reineger-Freeman Mines Co. The new company has installed a power-plant, and a new double-compartment shaft is being sunk which, when completed, will be 500 ft. deep. An incline shaft is being sunk 200 yards to the north. Development work is also being done to the east of Helmet Peak, from where copper ore is being shipped. The ore from this property is lead and zinc carrying silver, and passing into copper at depth.—The San Xavier Extension's

new shaft is now down about 120 ft., the old shaft being 275 ft. deep. At the new shaft a 25-hp. hoist, compressor, and power plant have been added.—The Alpha property has struck high-grade copper ore, one car having already been shipped.—The Hecla Arizona's shaft is now down 200 ft.—The San Xavier mine, owned by the New Jersey Zinc Co., is shut-down, being held as a reserve by the parent company.—The Plumed Knight is shipping ore to Tucson daily.

Tucson, February 2.

YAVAPAI COUNTY

(Special Correspondence.)—C. Hoyt of the Verde district has brought suit in the supreme court of New York to recover from G. G. Rice \$13,450 which he alleges is due on a promissory

MAP OF ARIZONA

note given in part payment for the Monster Chief property.—It is reported that a deposit of potash assaying 3.30% potassium has been discovered four miles west of Jerome.—It is announced by J. C. Haslet that certain interests of the United Verde Copper Co. contemplate entering the Chino Valley oilfield.

Prescott, February 1.

CALIFORNIA

ALPINE COUNTY

(Special Correspondence.)—A new strike of a large deposit of silver-copper-gold ore is reported to have been made re-

cently in the Curtz mine, just north-east of the Cryptic-Crater mines, in this county. The Curtz mine was taken over last December by William and Edmund Nelson and others. Three shifts of miners have been kept at work in the mine by the new owners.

Markleeville, February 7.

ELDORADO COUNTY

(Special Correspondence).—The mill formerly operated on gold ore from the Buzzard mine is being overhauled and provided with concentrators for the treatment of chrome ore from the Pilot Hill and Salmon Falls districts. F. Gurney is directing the work and the plant will soon go into action. A large tonnage of chrome has been opened around Negro hill, much of the material being of fair milling grade. Prospecting is active at numerous points.—Work has begun at the Teddy Bear, near Nashville, under the management of J. W. Cover.—The mill at the Montezuma, in the Nashville district, is being repaired and will be placed in commission soon. This property has been undergoing vigorous development for three years and a large tonnage of milling ore is reported. The shaft is 1000 ft. deep. J. C. Heald is manager and owner.—From the J. B. Williams mine at Shingle Springs 22 tons of copper ore was shipped last week. Opening of new ground is proceeding and the owner expects to ship steadily this summer.

Placerville, February 12.

INYO COUNTY

(Special Correspondence).—The mills of the Round Valley Tungsten, Standard Mines, and Tungsten Mines companies are operating steadily and treating about 450 tons of ore daily. The combined payroll aggregates \$30,000 per month. The three mines are looking well; late developments prove the orebodies more extensive and of higher grade than originally believed. The Beauregarde group of tungsten claims on Pine creek, in the White mountains, has been acquired by engineers reported to be connected with the E. J. Longyear Co. of Minneapolis. A survey for an electric power line has been completed and construction of a road is progressing. It has been decided to erect a 150-ton mill. A. B. Carpenter and E. E. McIntyre are directing operations. Cooper Shapley is manager.—The Black Hawk gold mine, now under control of the Yellow Aster Co., is developing favorably. New drills have exposed an ore-shoot 14 in. wide, and considerable free-gold quartz is reported in sight.—Henry Bopp is extracting gold ore from his property on the Garlock slope of the Rand mountains, 10 miles west of Randsburg. Recent milling of seven tons yielded \$800.—Mining continues active in the Keeler-Darwin field. The Cerro Gordo, Darwin Development, Santa Rosa, and other companies are operating steadily, and heavy shipments of silver-lead and zinc ores are going out from the Cerro Gordo and nearby properties tributary to Keeler.

Bishop, February 12.

PLUMAS COUNTY

(Special Correspondence).—News has been received here that the Anaconda Copper Co. has arranged to take over the interest of the Plumas Copper Co. in the Walker mine for \$500,000. This would give the Anaconda full control of the property, which is about 25 miles from Portola. The mine for several months has been developed under direction of the International Copper Co., and concentrate from the flotation plant has been shipped to the Tooele smelter. The new shaft is 450 ft. deep, and is reported to be in ore assaying upward of 8% copper and \$3 in gold and silver. The main ore-channel has been traced for 1000 ft. and late developments have been encouraging. The improved flotation plant has a daily capacity of 160 tons. All equipment is electrically driven. The International holds bonds and options on other properties in the district, and excellent ore is reported under development

in several claims.—The Engels Copper Co. is preparing for development of the Superior mine on a largely increased scale. This property has been extensively prospected with drills and high-grade orebodies demonstrated at depth. In the upper workings a good tonnage of profitable ore has been exposed. A heavy tonnage of ore from the Engels mine is going to the enlarged flotation plant, which is being continually improved. Before the end of 1918 the management expects to place the Engels group among the largest copper producers of California.—Many small properties near Keddie, at points between the Engels and Walker mines, and in Genesee valley are active.

Portola, February 9.

SHASTA COUNTY

Mrs. Rhoda B. Menzer has sold her 1042-acre farm, near Redding, to the American Dredging Co. for \$80,000. The last payment is to be made within a year from this month. The American Dredging Co. was formerly the Oro Electric Corporation. The farm has been prospected twice with Keystone drills. The first company that prospected it turned it down, but the second one has accepted it. It is estimated that 650 acres will pay well to dredge for gold. The ranch is at the mouth of Middle creek, which was famous in early days for placer-gold mining. Even the river adjoining the ranch has been dredged for gold at a profit, and now the purchasing company has determined that the bench land above the river shall be worked.

COLORADO

TELLER COUNTY

(Special Correspondence).—Owing to the car shortage the production of the Cripple Creek district for the opening month of 1918 totalled only 92,373 tons of ore, having an average value of \$10 and gross bullion value of \$925,430.—The treatment reported at the several plants was as follows: Golden Cycle 24,000 tons, \$480,000; Portland 9300 tons, \$190,650; Smelters 2500 tons, \$137,500; Independence Mill 37,000 tons, \$76,960; Victor Mill 19,573 tons, \$40,320.—The January dividends totalled \$273,500 and were paid as follows: Cresson Consolidated 10c., \$122,000; Golden Cycle 3c., \$45,000; Portland Gold 3c., (quarterly) \$90,000; Granite Gold 2c., (bi-monthly) \$16,500.—Six additional leasing companies, operating properties of the Stratton company, have entered the producing class since January 1. These are the Patterson-Bradley Leasing Co., Orpha May & Blocks, the Unity Leasing Co., Oscar Simms & Co., Layman & Upton, Vernon Peiffer & Co., and Green & Clifford.—The January output from the Stratton estate properties totalled 20 cars or about 700 tons, ranging from \$5 for the dump ore to as high as \$950 per ton.—The directors and officials of the Golden Cycle M. & R. Co., headed by A. E. Carlton as president, were re-elected at the annual meeting held at Colorado Springs on January 31. Stockholders will be paid the regular monthly dividend of 3c. per share, \$45,000, on February 10.—The Cresson Consolidated will pay its regular monthly dividend of 10c. per share, \$122,000, on February 10. It is officially announced that another rich orebody, with grab samples running from \$105 to \$300 per ton, has been opened in virgin ground on the 1000-ft. level. The orebody, believed to be the extension of the 1300 and 1400-ft. level shoots, opened last summer, is reported 30 ft. wide and extending over a length of 1000 ft.—The January output of the Acacia G. M. Co. was light, between 175 and 200 tons of 1-oz. ore.—Leases running for five-year terms have been issued to J. R. Woolwine and H. Kruse on the Mollie Bell and Kitty Wells, on Carbonate hill, directly north of Cripple Creek, by George K. Blaser.—The new rate for treating low-grade ores at the Independence mill is as follows: Ore running \$3 per ton, \$2; from \$3 to \$2.50, \$2.25; \$2.50 to \$4, \$2.50; \$4 to \$4.50, \$2.60; \$4.50 to \$5, \$2.75 per ton. The Golden Cycle company, it is reported, will

meet these charges.—The Roosevelt tunnel was advanced 141 ft. and the Cresson cross-cut from the tunnel-level 105 ft., making a total of 249 ft. during January. The flow from the tunnel has fallen to 3720 gallons per minute.

Cripple Creek, February 8.

IDAHO

BONNER COUNTY

The adit at the Armetter Mines Co., in the driving of which several excellent records for speed were made, reached its objective on January 30, cutting the vein at 3505 ft. from the portal and at a vertical depth of 1600 feet. The adit has passed through five feet of concentrating ore, assaying 25 oz. in silver per ton, and has not yet reached the foot-wall.

MONTANA

LEWIS AND CLARK COUNTY

In the Grass Valley district the Helena Mining Bureau has surpassed its former record by sending to the smelter nine carloads of ore during January. A new compressor has been added to the mechanical department, making two in operation. Ore is being stoped from a shoot 200 ft. long in the 300-ft. level. The Rock Rose has uncovered two feet of galena and carbonate ore at 200 ft. and has other ore on the 300-ft. level that is being mined and shipped.—In the Scratch Gravel hills the Thomas Cruse Development Co. has found a strong shoot of ore at a depth of 640 ft. on the incline, and 1000 ft. east of the shaft. The ore, which is quartz, carries considerable silver and lead in addition to the gold content.—The Shannon shaft at Marysville has been completed to the 650-ft. level, making an additional 150 ft. The ore-shoot is west of the shaft and a drift will be run toward it during the month. The ore from the Shannon goes to the mill at Gloster, as also does the output of the Piegan-Gloster. The Barnes-King company is the owner and operator.—The St. Louis Mining & Milling Co. is milling ore that was mined from the Blue Bird-Hickey adit while the property was being explored by the Marysville Gold Syndicate.—In Lump gulch the Amalgamated Silver Mines Co. has deepened its shaft to 230 ft. and will continue to the 250-ft. level before driving.—The Economy company is sinking a winze on a rich shoot of ore at the 300-ft. level in Mitchell gulch.

SILVER BOW COUNTY

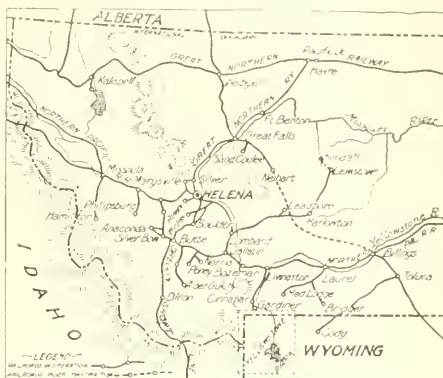

(Special Correspondence.)—The annual meeting of the Montana Section of A. I. M. E. was held at the Silver Bow Club, Butte, February 1. After an excellent dinner, an election was which resulted in the following officers for the ensuing year: N. B. Braly, chairman; B. N. Dunshee, vice-chairman; E. B. Young, secretary-treasurer; C. D. Demond, F. W. Bacon, executive committee. An excellent and varied technical programme was the feature of the session. C. H. Clapp spoke at length on a comparison of the contact deposits of Vancouver and adjacent islands with those of Arizona. With suggestive generalizations he showed that as striking differences exist in the contact deposits as in the geologic structure and physiography of the two regions. C. D. Demond discussed the efficiency and design of hydraulic classifiers, and F. W. Bacon shaft-sinking, while James R. Evans, who has returned recently from Africa, entertained the meeting by an interesting account of diamond mining and elephant hunting in the Belgian Congo.

Butte, February 4.

(Special Correspondence.)—The 2200-ft. level on the Adirondack vein at the North Butte has been driven 88 ft., 66 ft. of which was in ore averaging 7.5 ft. wide and assaying 4.8% copper and 2.8 oz. silver per ton.—The 2400-ft. level on the South Croesus vein has been advanced 110 ft., 86 ft. of which

was in ore averaging 4 ft. and assaying 2.5% copper and 3 oz. silver per ton. The 2500-ft. level on the Snowball vein has been advanced 49 ft., showing ore of an average width of 1 ft., assaying 4.5% copper and 7 oz. silver per ton. The 2400-ft. level on the North Berlin vein has been extended 58 ft., showing ore of an average width of 4 ft., assaying 5.1% copper and 6.1 oz. silver per ton. The following development work was done during the quarter: cross-cuts 4 ft., drifts 305 ft., raises 338 ft., total 647 ft.—The Sarsfield shaft on the East Side properties is now 495 ft. below the collar, and will be sunk another 205 ft. before levels and cross-cuts are driven; a 200-hp. compressor will be installed to cope with the excessive flow of water. During the quarter 31,829 tons of ore and three tons of copper precipitate were shipped.

During January the East Butte Copper Co. produced 2,574,140 lb. of copper at its Pittsmond smelting plant, while in December only 2,500,000 lb. was produced. In January the silver production amounted to 82,175 oz., against 55,000 oz. for December.

PART OF MONTANA

ber, a gain of 27,175 oz.—A large increase in output has been shown during January by the Anaconda Copper Mining Co., which produced 24,900,000 lb. of copper, as compared with 22,500,000 lb. in December, an increase of 2,400,000 lb., and 4,500,000 lb. of zinc. These figures show that the company is rapidly approaching its normal production, and when the additional roasters are in operation at the Great Falls plant, the electrolytic plant will give the Anaconda company an estimated monthly zinc production of between 6,500,000 and 7,000,000 lb. An average day's hoisting of copper and zinc ore is said to be about 18,000 tons. On February 2, the Anaconda company handled 1000 tons of ore from the North Butte company, this being the largest daily tonnage from that company since the fire, last June.—It is expected that the Anaconda will resume the purchasing of zinc ores from custom shippers shortly, and it is rumored that it will increase the rate of payment from one-half to one and one-half cents per pound for the zinc in the ore. This was the original price set, but was cut when the slump came and the disposal of the finished product became difficult.—The Butte & Superior Mining Co. produced 14,600,000 lb. of zinc, in the form of concentrate, during January. In December the zinc output was 13,400,000 lb., showing an increase of 1,200,000 lb.—The silver production in January was 265,000 oz. as against 250,000 oz. in December. The total amount of ore mined in January was 47,000 tons, while in December only 43,000 tons was hoisted.—The concentrate tonnage for January was 14,600 tons, as against 13,400 tons in December.

Butte, February 9.

NEVADA

ESMERALDA COUNTY

(Special Correspondence).—Ore of shipping grade has been uncovered at a depth of 400 ft. in the Red Hill-Florence mine. The discovery was made in a drift extending from the raise driven from the 500-ft. level to prospect territory adjacent to the old Rogers-Syndicate lease on the Florence. Joseph B. Kendall, the manager, expects to start shipment soon. Re-timbering of the main shaft from the 500 to the 600-ft. level has been completed, and the 600-ft. station placed in shape for comprehensive work. Drifts will be extended to a shoot formerly worked below the 500-ft. level of the Florence. The Red Hill-Florence is a consolidation of the old Red Hill and Florence Extension mines.—The Atlanta company has completed the station on the 1900-ft. level and started a cross-cut east to intersect the main vein. This work is in the shale, but the cross-cut is expected to enter the granitic quartz within a short distance. A second winze has been started from the 1750-ft. level to explore the hanging-wall section of the Atlanta vein. The water-flow has decreased in the first winze and mining is proceeding more rapidly.—The Great Bend is shipping ore averaging \$44 per ton in gold, and the eastern workings have been connected on the 300-ft. level with the Lockhart shaft. This is being unwatered, preliminary to the vigorous prospecting of a promising area.—It is reported developments will be resumed at the Lone Star.

Goldfield, February 9.

MEXICO

JALISCO

The cyanide mill at the El Favor mine in the Hostotipaquillo district was burned by bandits on September 22, but the news has only recently come to hand. The damage was confined mainly to the stamp-batteries. The mill contained 35 stamps, and has a capacity of 250 tons per day. It is to be re-built at once by the Makeever brothers, who are the controlling owners of this property. James H. Nelson is resident manager. The mine is 1000 ft. deep and is said to be making a handsome showing, the lode being 40 to 50 ft. wide and averaging 750 gm. silver per metric ton. In the same district is the Cinco Minas property, which is making handsome profits under the management of Frank Oldfield. The mine is 1300 ft. deep, and shows 50 ft. of lode, of which 20 ft. assays a kilogramme of silver per metric ton. The mill contains 50 stamps and the machinery required for cyanidation. It is said to be the best designed mill in Mexico. Its present capacity is 400 tons per day, but this is to be increased to 600 tons per day forthwith.

NUEVO LEON

(Special Correspondent).—The Mexican government will impose heavy financial penalty upon all mine-owners who are now delinquent or may become delinquent in the payment of mining taxes, according to official announcement received here by American and other mining men. The notice reads: "The treasury department of the Mexican government has ordered that mining taxes shall be collected from January to April, as follows: For fiscal year 1916-1917, with fine of 100% of the total amount of the taxes; for first third of the fiscal year 1917-1918, with fine of 75%; second and third third of 1917-1918, with fine of 50%; first third of 1918 without fine if paid in January or February, and with fine of 25% if paid in March or April."

Monterrey, January 29.

PHILIPPINE ISLANDS

The Colorado Mining Co. is re-constructing its cyanide plant at Aroroy; ball-mills will replace the old 20-stamp mill. J. S. Colbath is manager of the mine and E. H. Clausen is in charge of the mill-construction.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

W. A. PRICHARD is returning to Pato, Colombia.

ROLLA E. CLAPP has gone from San Francisco to Boston.

C. S. HEZIG has moved from Salt Lake City to 27 William street, New York.

D. M. FOLSON has been appointed petroleum administrator for the Pacific Coast region.

A. ANGUS has been appointed manager of the Tough Oakes mine, at Kirkland Lake, Ontario.

DOUGLAS MUIR passed through San Francisco on his way from Austin, Nevada, to Pasadena, California.

R. C. WARRINER has resigned as consulting engineer to the Crown Mines in order to join the Air Service of the British army.

M. M. MAKEEVER, of Boston, and L. BRADBURY, of Los Angeles, have returned from Mexico to San Francisco, on their way home.

FALKENBURG & LAUCKS has ceased to exist as a firm, being replaced by FALKENBURG & Co., assayers, at Seattle, Washington.

P. S. COULDBREY, formerly superintendent of the Cerro de Pasco mine, in Peru, is now serving with the Royal Engineers in England.

G. J. STEELE, sergeant, is with the British mission that is instructing American soldiers in gas warfare. He is not in the Military Police.

CEDRIC SHEEKER, Lieutenant, of Tucson, Arizona, was married on February 5 to Miss Pauline de Brutz Justice, of Berkeley, California.

ARTHUR E. G. COLLINS, son of George E. Collins, of Denver, has been awarded the Military Cross for "great gallantry and fine qualities of leadership and organization under fire," while serving as lieutenant in the Royal Engineers near Havrincourt, in France.

G. H. CLEVINGER has resigned as Research Professor of Metallurgy in Stanford University and is now engaged in directing the co-operative experimental work that is being done by the U. S. Bureau of Mines, Netherlands East India Government, and Research Corporation of New York.

Obituary

WILLIAM STANLEY, one of the pioneers of the Klondyke, died on February 6 at Pomona, California.

ANGUS M. HADGIE, the discoverer of gold on the Fraser river, B. C., and later identified with mining in Eldorado county, California, died at San Luis Obispo, California, on February 6.

AUGUSTE MATHEZ died at Denver on February 4. He was born at Brooklyn, New York, in 1856 and graduated from the Columbia School of Mines in 1879. His first work as mining engineer was in California and Nevada, then in Gilpin county, Colorado, with headquarters at Denver. He was at Dawson in the early days of the Klondyke excitement and was examining mines for the Guggenheims in China at the time of the Boxer rebellion. He traveled widely in the exercise of his profession, going to Australia, Mexico, and Central America. He was considered a man of good judgment in the appraisal of mines. Kindly in disposition and genial in temper, he won friends easily wherever he went. He is survived by his son, Forrest Mathez, who is engaged in mining, and by a daughter Claire, the wife of James Arkell, who is operating mines in Mexico.

THE METAL MARKET

METAL PRICES

San Francisco, February 11

Aluminum-dust (100-lb. lots), per pound.....	\$1 00
Aluminum-dust (ton lots), per pound.....	\$0 85
Antimony, cents per pound.....	16 00
Antimony (wholesale), cents per pound.....	14 00
Electrolytic copper, cents per pound, in carload lots.....	23 50
Electrolytic copper, cents per pound, in small quantities.....	24 07 1/2
Fe-lead, cents per pound.....	7 25—8 00
Platinum, soft and hard metal, respectively, per ounce.....	108—116
Quicksilver, per flask of 75 lb.....	\$125
Spelter, cents per pound.....	10 00
Zinc-dust, cents per pound.....	20 00

ORE PRICES

San Francisco, February 11

Antimony, 45% metal, per unit.....	\$1 00
Chrome, 34 to 40%, free SiO ₂ , limit 8%, f.o.b. California, per unit, according to grade.....	\$0 00—0 70
Chrome, 40% and over.....	\$0 85—1 00
Magnesian, crude, per ton.....	\$8 00—10 00
There is little demand for either calcined or crude magnesite.	
Manganese: The Eastern manganese market continues fairly strong with \$1 per unit Mn quoted on the basis of 48% material.....	
Tungsten, 60% WO ₃ , per unit.....	26 00
Tungsten ore remains firm.	
Molybdenite, per unit MoS ₂	\$40 00—45 00

EASTERN METAL MARKET

(By wire from New York)

February 12—Copper is inactive at 23.50c. all week. Lead is quiet and firm at 7c. all week. Zinc is dull and steady at 8c. all week. Platinum is unchanged at \$108 for soft metal and \$116 for hard.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

The Government is buying and using large quantities of various grades of zinc designated as grade A, grade B, and grade C. There is considerable confusion in the mind of the general public as to what distinguishes these various grades. The following tables, compiled from the government specifications, throws light on the subject and gives the chemical requirements:

	Grade A %	Grade B %	Grade C %
Zinc, minimum.....	99.85	99.35	98.00
Cadmium, maximum.....	0.05	0.50	0.75
Iron, maximum.....	0.03	0.03	0.03
Lead, maximum.....	0.07	0.10	1.00
Sum of cadmium, iron, and lead, max.....	0.10	0.50	1.50
Aluminum, maximum.....	none	none	trace
Other elements (tin, arsenic, sulphur, antimony, etc.).....	none	trace	trace

Grade A is the purest. Only virgin spelter of zinc, that is, spelter made from ore or similar raw material by a process of reduction or distillation and not produced from re-worked metal, shall be furnished for grade A. High-grade zinc shall be furnished for grade B; this may include refined zinc, that is, metal resulting from short ends, but not scrap metal. Grade C is nearly the same as prime Western zinc, but is regarded as a little better.

ORES

Tungsten: There has been 100 tons of wolframite mined in this country at \$9.50 per unit but no takers so far reported. A few tons have been done recently at the actual price of \$10 to \$12, showing a demand for the highest price. Refined tungsten is not being sold with discounts. Ferro tungsten is quoted at \$2.50 per lb. of tungsten content.

Molybdenum and antimony: Transactions of late have been reported on molybdenum concentrate at \$2.15 per lb. of MoS₂ or \$5 to \$6 per unit. Antimony ore is nominal at former prices of about \$1.75 per unit.

The American Smelting & Refining Co. was soon have materially increased its Mexican operation through resumption of activity in Chihuahua. In fact the General Electric has been closed down for the past four years, both mining and smelting there, the company has its largest and most important plant in Chihuahua.

It is understood that the United States government will soon send a few consuls to that district. A man who has been in the consular service for some years and who is well conversant with conditions among Latin Americans. An engineering and construction force is expected to leave for Chihuahua shortly to put into condition the Smelting company's plants.

Eastern Metal Market

New York, February 6.

'Coalless' Monday was again rigidly observed this week, and no business was done in metals, business houses and the New York Metal Exchange all being closed. The expectation of its being the last day of the kind has been upset by temperatures below zero during the last two days.

Copper is moderately active at regulated levels, but there is a scarcity of spot in some cases.

Tin is active and strong for future positions, but spot metal is unobtainable.

Lead is very quiet, but firm and unchanged.

Zinc is dull, but slightly firmer.

Antimony is lifeless, with a lower tendency.

The steel industry has suffered unparalleled weather and transportation conditions during the past week and through the entire month of January. This is reflected by the January pig-iron statistics of 'The Iron Age.' These show that the output fell last month to 2,411,768 tons, or to 77,799 tons per day, against 2,882,918 tons in December, or 92,997 tons per day. The month was the smallest since May 1915. Active furnaces on February 1 were 310, with 321 active on January 1, and 345 on December 1. How the industry has been suffering is shown by the fact that in May 1915, only 20 furnaces were at work to produce 73,015 tons per day, whereas last month it took an average of 315 to produce 77,799 tons per day. The steel industry of the country is operating on a 50% basis, with some plants at no more than 25% capacity. Costs have advanced so greatly that a downward revision for April will have a strong argument adverse to it.

COPPER

The principal topic of conversation is the effect of the unprecedented winter in the Eastern district of the United States. Its severity in low temperatures has never been equalled, particularly in New York, and this, together with heavy snows, has been general for two months all over the East. Below-zero weather for the third time is just passing over the East, and it is intensifying again the already bad railroad congestion. Some anxiety is felt as to the possibility of this condition affecting the supply of raw copper, in the forms of blister copper and copper matte, which comes from the West to the refineries in the East. Should this supply decidedly diminish, a scarcity would develop, temporary at least. A good stock is now on hand at the refineries but the flow of the raw supply must not be stopped for long. A scarcity of spot copper already exists in the jobbing market, one dealer reporting yesterday that he had none to sell and could get none. There is quite a general scarcity in Chicago also. At the Government prices of 23.50c., and 24.67½c., a fair business is being done, with orders booked to June 1, subject to Government needs. It is believed that there will be plenty of copper for domestic users in the long run. The production of raw copper is on a large scale, according to January reports so far published. Exports for January are estimated at about 37,000 gross tons, with imports at about 19,000 tons.

TIN

Spot tin continues to be unobtainable, and there is no prompt or even nearby market. The only nearby tin is that which is arriving, and it is applied on old contracts. Spot and Straits continue nominally at 85c. per lb., New York, with the average for January at 85.13c., nominal. The business done in the last week has all been in futures. Yesterday there was considerable inquiry from two buyers in particular, which resulted

in a moderate amount of business being done. Late last week there was also some buying of futures, but the volume was not large, nor were there many sellers involved. There has been some more Government confiscation of tin. Two vessels last week brought in about 500 tons, all told, of Banca tin, which was commandeered by the Emergency Fleet Corporation. It is believed that it has been or will be restored to the original owners if they are found to be of the proper 'brand'. Deliveries of tin in January, according to the New York Metal Exchange, were 4642 tons, of which 3192 tons came East from Pacific ports. Stocks and landing on January 31 were 767 tons. The same exchange also publishes yearly statistics, according to which supplies of tin in 1917 were 120,918 gross tons, against 117,250 tons in 1916, and 121,800 tons in 1915. Deliveries were 124,423 tons in 1917, against 113,377 tons in 1916, and 118,906 tons in 1915. The visible supply for 1917 was 17,766 tons, as compared with 20,737 tons in 1916, and 16,216 tons in 1915. No arrivals for February have been reported. Spot Straits in London yesterday was quoted at £301 per ton, against £299 10s. a week ago.

LEAD

The market is firm, but very dull, and without actual interest. Quotations are about nominal at 7c., New York, or 6.85c., St. Louis, in the outside market for early delivery with the Trust price unchanged at 6.75c., New York. Demand is light and has been for some time. There has been some interest in spot lead, and a few carloads have been sold at 7.50c., New York. The supply at this end is dwindling, due to non-arrivals from the West, caused by the continued railroad congestion which has been intensified by fresh storms and low temperatures.

ZINC

Railroad congestion, storms, and cold weather are interfering with the zinc market. Conflicting orders from the Government are by no means an unimportant factor in the general confusion. It is admitted that large quantities of zinc of all grades are being consumed on Government orders, but there has been no little secrecy regarding the placing of these orders. The market as a whole continues in a dull condition; it lacks animation and snap. There is occasional buying, and the prevailing quotation is about 7.50 to 7.75c., St. Louis, or 7.75 to 8c., New York, for prime Western for early delivery, with modest premiums asked for future positions. There seems to be plenty of zinc to meet present demands, but one large producer here predicts a shortage ultimately. It is stated in various quarters that a price of 12c. per lb. has been fixed by the Government on grade A zinc. This lacks official announcement, but it is generally regarded as true. A fuel shortage is looming up as a serious factor at some Western smelters, even at those producing sulphuric acid, which the Government needs urgently. Sheet zinc is quoted at 19c., base.

ANTIMONY

The Government continues to inquire, and probably to buy, but its purchases are not made public. The market is lifeless at 14 to 14.25c. per lb., New York, duty paid, for Chinese and Japanese grades for prompt or early delivery.

ALUMINUM

Lack of demand continues, with quotations unchanged at 36 to 38c. per lb., New York, for No. 1 virgin metal, 98 to 99% pure, for prompt and early delivery.

EDITORIAL

EIGHTY THOUSAND tourists, it is reported, intend to come to California this season. If they are invalids, they do well in coming and they are welcome; if they are in good health, they had better stay at home and set aside the cost of their proposed tour as the nucleus of a fund to enable invalided soldiers to obtain the benefit of the Californian climate. At a time when the congestion on the railroads is a cause of national perplexity and during a time of crisis when all our energies and thoughts are concentrated on the big work in hand, it is wrong for people to go on pleasure-seeking tours. We class them with Mardi Gras balls, golf tournaments, and irresponsible gaieties of every kind.

CLEAR and well-reasoned discussion on the physics of flotation is a pleasure to print, and this week we present a letter from a modest technologist who has not even divulged his identity to the editorial ear, but who possesses a real understanding of the electrical conditions that exist in the complex mass of wetted pulp with its particles of mineral and gangue, its oils, and the interfacial surfaces with their active energy-relations. The suggestion of our anonymous contributor that the effect on the adhesions that cause flotation, resulting from the latent charge carried on the surface of metals, should be investigated experimentally in well equipped physical laboratories, will not pass unheeded.

CO-OPERATION is a word that is being sung on many keys, some of them minor. Mr. F. L. Ransome has been investigating the quicksilver industry of California in behalf of the U. S. Geological Survey. Shortly after the managers of mines had replied to his intelligent queries they received a letter from Mr. William Forstner, a thoroughly competent engineer, asking them to state what was their cost of operation, he being commissioned to make the inquiry in the interest of the U. S. Navy Department. We would suggest that telephonic communication be established between the Survey and the Navy offices at Washington. Meanwhile it is interesting to note that quicksilver ore containing only 0.3% of mercury is being worked profitably at the Oceanic mine, in San Luis Obispo county, because the former management had blocked out a large tonnage ready for stopping just before the market collapsed and

the operation of the mine was discontinued. At the New Idria, in San Benito county, the premier quicksilver mine of California and of the Americas, a 0.45% ore is being exploited to advantage, so that, as a generalization, it may be said that $\frac{1}{2}\%$ quicksilver is within the economic limit in California. Apparently the economic limit at Washington also can be enlarged by co-operation.

INTERFERENCE with production from American enterprises, here or abroad, hinders in some degree the success of our struggle against Germany, and is, therefore, assisting the Enemy, whether or not it be done deliberately with that intent. It is pertinent to call attention, as an instance of such injurious interference, to the fact that complaints are coming from American mining companies operating in Mexico because of the difficulty to secure permits for the importation of dynamite. Formerly it was sufficient to telegraph to the Minister of War at Mexico City; now the Minister says that he must refer the request in each case to the State government. Not only does this entail vexatious delays, but, in one instance that has been brought to our attention, the Governor of the State wired his consent, and still no action was taken by the War Department.

PREPARATION for business after the War should not be neglected. Reliance upon foreign trade to keep our factories going and our workmen employed is apt to prove disappointing. We have noted a disposition, which we think rests upon hasty reasoning, to assume that a period of reconstruction in Europe will begin the moment peace is assured, and that it will call immediately for enormous contributions of metals and manufactures from this country, sufficient to create an era of prosperity. This view is too optimistic. As soon as an armistice is arranged a period of uncertainty will supervene; no man will know whether the conference will or will not lead to an acceptable peace. Especially will this be so if overtures should be entertained before Germany has been brought to her senses, that is, before the Allies have won victory on German territory. It appears not unlikely that the Kaiser will sue for peace before such a collapse of his power. The negotiations over a general treaty of peace will consume many months,

for questions of the utmost complexity and gravity, affecting every country in the world, will be under consideration. It is evident, therefore, that after the demand for military supplies will have ceased a long period of stagnation is inevitable before normal commercial intercourse between the nations will be resumed. What can we do in the interim to avert serious financial stress? It is evident that we must turn again to our domestic problems of industrial development. These are now halted, because the materials needed are unavailable while our activities are centred upon the production of munitions of war. Nevertheless, the wise manufacturer will endeavor to keep in touch with the possibilities of business at home; he will not allow his organization for gathering information as to new projects in his own country to become crippled; he will not fail to advertise in order to keep his name prominently before the public, and he will prepare to follow the indications of business brought in answer to his advertisement so as to be ready to take advantage of them as soon as the Government's call upon his activities ceases. Above all, he must not count too heavily upon foreign business for a considerable period after the War. Europe will find an enormous quantity of raw material ready to hand in the scrap and wreckage that has accumulated during these years of struggle: this will serve as an important source of supply for her shops. We must not forget the recent announcement of M. André Tardieu, French High Commissioner to the United States, that France is able to furnish 20 divisions of our army with all the guns and ammunition that they may need for six months in addition to her own requirements for an army of over four million men now in the field. This gives an idea of the manufacturing capabilities of that country. England also has developed her equipment for manufacturing during the War tremendously. There we confront potential competition that should dispel dreams of a continuing foreign demand for our manufactures adequate to maintain our industrial operations at high pressure. We must keep our house in order to meet the strain inevitably due when the period of re-adjustment begins.

FIXATION of zinc prices, within narrow limits, has been achieved by those interested in securing fair treatment of the industry by the Government. The chief war-demand is for the higher grades; consequently the official price affects only what is known as 'grade A', which is now to cost 12 cents per pound, this price applying to Government purchases and to the open market. Grade A conforms to a minimum of 99.85% zinc, with standard limitations for other impurities as presented on our metal-market page last week. Lower grades are left to shift for themselves, and as grade A represents but a small proportion of the total zinc output the effect on the quotations for 'prime Western', will be small. Even the inclusion of sheet-zinc in the official list at 15 cents per pound will prove of comparatively little benefit for the same reason. Apparently this would indicate a price

for prime Western a shade below recent quotations, and the zinc-producers will find it necessary to adjust themselves to this unfavorable condition.

The Mining of Oil

On February 14 a meeting of operators and engineers engaged in the exploitation of oil in California was called by Mr. Fletcher Hamilton, the State Mineralogist. The invitation to attend was accepted in the right spirit, so that the small room in the Mining Bureau was crowded. Mr. Hamilton explained his purpose, which was to obtain from the operators a better recognition of the function of the engineer or technical advisor. He called upon Mr. R. P. McLaughlin, at the head of the special Department of Petroleum and Gas, to inform those present what technical assistance the Bureau was giving and how the oil companies could co-operate with the Bureau in rendering that assistance of the greatest practical value. Our readers are aware that Mr. McLaughlin and his staff have made a special study of the detrimental effects of water infiltration on the flow of oil-wells and of the means to diminish this check on production. He complained that many companies failed to give the information required and that others gave it so carelessly as to stultify the inquiry; he acknowledged the cordial assistance given by sundry large companies, the officials of which were sufficiently enlightened to appreciate the aid of technology, and he asked those present to make suggestions for the furtherance of the good work. A number of geologists and engineers took part in the discussion to useful purpose, the old reactionary note being struck by only one speaker, who talked the ancient piffle about practical men being more reliable than technical graduates, raising a cheap laugh by introducing the gag about those that live down the effects of education. During the discussion the question was asked, what is an engineer; and the query was raised whether oil exploitation was mining. An engineer is a man engaged in the work of engineering, which in mining is the directing of operations designed to extract mineral from the earth at a profit. The idea of profit is implicit. Mining, and the engineering essential thereto, is not a scientific pursuit, but a business, the object of which is the making of money legitimately. The doubt whether the winning of oil be mining is a belated survival of popular ignorance. Mining is an art in which science—notably geology, mechanics, and chemistry—is used to find and benefice mineral deposits. The search for oil involves the use of geology even more directly, and more successfully, than the seeking for metals. The application of mechanics to drilling is obvious, and the use of chemistry in the refining of oil requires no emphasis. The idea that oil-exploitation is not 'mining' because the product is liquid is without reason, for sulphur, salt, and other minerals are extracted in liquid form, and even gold, in placer mining, is pumped. The exploitation of oil is an integral part of mining, and it is time to set aside any apologetic distinction. In any event the owners of oil-wells in Cali-

fornia know better, even if they have come but slowly to the recognition of the money-value of technical science. In this they are but human—which is to err. The pioneers of mining in this State, the gold-seekers, thought to dig for wealth without the aid of technology and succeeded in doing so during those spacious times of the Golden Age when the fruit had but to be picked. Later they found that they needed all the technical aid that was forthcoming, and more; they learned, as the oil-well driller has done, that mechanical skill must be guided by the geologist and supplemented by the chemist. We are glad, therefore, that the Mining Bureau is conducting a campaign of education beneficial to the community in general and to the oil-mining companies in particular. The State Mineralogist is to be congratulated on his prevision; we feel confident that he will receive the support of the profession, and also, we trust, of the business community.

The Pen or the Sword

During recent weeks there has been more talking than fighting. This befits civilization, but it is a pity that similar talking did not forestall the beginning of this world-war, as it might have done, instead of starting long after the great calamity was well under way. Our scholarly President appears to believe that the pen of democracy is mightier than its sword, and to this belief the peacefully minded citizen will incline to give support, provided that the other party to the controversy does not drive the point of his sword through the reasoned argument. While the President was conducting an open-air debate with Count Czernin, the Kaiser was apostrophizing his troops at Hamburg in his usual truculent manner and re-stating the Prussian resolve to compel the world to submit to "the victorious German army." The pen and the sword were being flourished against each other. It may be that the legal weapon will triumph over the lethal, and that the politicians will overthrow the militarists, but the effort is attended by the grave danger of weakening the national resolve to see this thing through. If the President succeed in detaching Austria from Germany, it would go far toward ending the conflict, as all of us devoutly wish, if it could be done without merely shortening and solidifying the Teuton lines, and without rendering assistance indirectly to Germany through Austria's restored rights as a neutral, and also through imposing hardships upon Italy that might bring discomfiture to her Government and react against her political integrity. Yet we fear the enfeebling effect of this talk from high places so long as "Germany is apparently willing and able to send millions to their death to prevent what all the world [outside Germany and her vassal countries] now sees to be just." So says the President, and he continues: "Our whole strength will be put into this war of emancipation from the threat and the attempted mastery of selfish groups of autocratic rulers—whatever the difficulties and the present partial delays." But

will not the difficulties and delays obtain reinforcement from the continued parley with the outlaw and his gang? We fear the enfeeblement to follow protracted debate and the lowering of our own morale in the worthy effort to settle with the criminal—Austria—that was willing to be used as a tool for the sinister purposes of Prussia. Already we discern signs of indecision among our people; there is too easy an acquiescence with the contention that the task of curbing the outlaw is beyond the strength of England and France, even if we send increasing help to them. We do not believe it; wrong shall not triumph, frightfulness shall not prevail, if the United States, England, and France stand firm. Do the men in the trenches show a weak stomach, does this poison-gas of compromise with the enemy come from there, or does it emanate from the weak-kneed that stay at home? We do dishonor to the gallant French soldiers, to the resolute British, and to our own brave boys, now beginning to take their places on the battle-front, if we imagine that any of them for a moment doubt the issue. The one virile thing today in this world of Prussianism and Bolshevism is the young man able and willing to fight for the decencies of civilization, the sanctity of law, and the rights of humanity. We at home are either too old to fight, too young, or physically unfit, or women, or slackers; the real man is he that has shouldered arms and set forth to protect his home, to defend his country, and to preserve his self-respect. That is our view. Yet one cannot ignore the opposite opinion, as expressed by several thoughtful papers, notably the 'New Republic,' which we read for our sins and as a counter-irritant. It is held by these that a political victory is more desirable than a military decision because the one will unhorse the Hohenzollern dynasty, whereas the other will leave the German people under the control of their present leaders, unrepentant and unreconciled. They think it wiser to scheme for a political revolution at Berlin than to carry the war across the Rhine. The purpose of the Allies, they say, is to destroy military imperialism and make the world safe against such deliberate aggression as Germany prepared for forty years before 1914. With this we agree. Next they claim that to ensure the attainment of this purpose we must conduct the War so that at the end of it Germany will be under democratic control, in short, the expectation is that the War will be ended by a revolution in Germany. This also is a consummation devoutly to be wished, although declared unrealizable by that seasoned statesman, Clemenceau; in any event, shall we bring it to pass quickest by talking or by fighting? Does not the talking suggest a lack of confidence in the fighting? Are the German people more likely to be convinced by the pen or by the sword, by the mouth or by the arm? The talkative method might hope to succeed if the Germans had not proved themselves more loyal to their government than any of the peoples of the Allies to their respective governments. Are we not playing with fire when our hay-field is more dry than that of our enemy? Much as we hate the Prussian and his bestial ways, much as we may condemn

the German people for becoming the pliant tool of the dynastic ambition of the Hohenzollerns, we must recognize that the one will not throw off the yoke of the other until a military decision has proved the madness of the idea of bringing the world under the heel of the Prussian goose-step. The suggestion that we are not fighting the German people but only a group of bad men by whom they have been misguided is a mere ostriehism; we are fighting a united people, a people so ready to subordinate themselves to the idea of the State and to the direction of their over-lords that they act as if without conscience and without shame. Our talk will not undo the education of forty years of preparedness for piracy, so long as the German armies devastate Belgium, pollute the fair fields of France, and push Russia into the pit of anarchy. Let us talk with a democratic Germany, by all means, but let us stop fooling ourselves with the notion that our talking will make Germany a democracy. They, the German people, not their leaders only, appealed to the sword when the pen lay ready to their hand; they must put aside the sword before the pen can be used for something more serious than making a few timid marks on another 'scrap of paper.'

Gold, Silver, and Credits

In discussing the question of silver and bi-metallism last week, Mr. George E. Farish viewed the proposal for an issue of Federal Reserve bank-notes at an angle different from the one that led us to see in it a means for converting the debit balance of foreign treasuries, in our national account with them, so far as withdrawals of remelted silver coin are concerned, into a basis for expanding the currency. Mr. Farish considers it an anticipation of future purchases of silver to replace that exported on requisition from our Allies against the credit-allowance authorized by Congress. It would be a considerable strain upon credit to monetize our credit-balance with the Allied governments, but to issue warehouse certificates against unladen eggs, so to speak, would be to subject the elasticity of the media of exchange to a still more dangerous tension. No doubt the average amount of silver will be produced this year and next, for the law of averages is a safe reliance; indeed, we may assume that the Produce Exchange can make a fair guess at the number of eggs to be laid between now and next Christmas, barring cholera, and Germans, and other calamities; but the less we anticipate future production of anything the safer is our basis for acquiring present necessities at a reasonable purchasing-value of our credit medium. Credit is based after all on the supposition of the ability of the debtor to liquidate, and not to collapse in bankruptcy if called upon to settle. The credit of a government is based on the same thing, and incidentally on the belief that all men will not simultaneously demand coin. On that depends the elasticity of currency issued against a certain amount of token-metal, which still is accepted with veneration as the monetary fetish, because it

is quite heavy, nearly indestructible, undoubtedly pleasing to the eye, and for the most part useless in itself. If some cautions critic should force us to a re-statement of this last opinion we would submit that gold and silver possess but little intrinsic value, certainly far less than iron, or copper, or zinc; and we would then remind him that silver was more useful in the arts than gold, not alone because of its greater abundance, but because it is more easily worked, more chemically and metallurgically subservient. This is dealing with a subject regarding which we know there is no agreement among economists nor likely to be for generations to come. Therefore we may indulge ourselves in the defiant heresy of maintaining that the esteem of token-money bears an inverse relation to its intrinsic worth. We believe that the market-gauge dollar would possess transcendent merit as compared with gold, if—a huge dubitative—the world were weary of strife and difference, and were to settle down to the declining period of the career of the human race, with one government, one language, one blissful ideal of ease and inanity, sans flag, sans conscience, sans progress to any higher destiny. So, turning from the darkening sunset to the hopeful East, we still believe in gold as a fetish that man will cherish long, and on which he will base his exchange with his fellows, in a practical forward-moving world that denies the right of Germany to put us all into a universal well-ordered Teutonic filing-cabinet, or of Trotsky to bless us with the liberty of self-determination in a universal 'anarchy', or no-government, as designated under the red rag of the Bolsheviks. We still believe that silver is the weak brother, to be bought by gold, not to be given equal inheritance in the world of business. It is possible to fix the price of silver, to determine how much silver one gold dollar will buy, but if we do that we must come to definite and long-time agreements on the matter with all Europe, and with Japan and China; otherwise, as sure as the sun is in the heavens, the nations not in the agreement soon will have the gold in their vaults while we shall be stuffed with silver that can be exchanged only at a ruinous discount from its cost in gold. If, without such an agreement, we use the unmined silver as a basis for expanding credit, there will shortly be a sharp discrimination between Federal Reserve notes and the issues based on expectations of silver yet to come. Mr. Charles A. Porter, writing on this subject elsewhere in this issue, shows how readily even gold may lose its purchasing power, which disposes of the importance of intrinsic value as a factor in the monetary efficiency of any metal. It is safer, in the absence of universal treaties for stabilizing silver, to let the market demand regulate the price in the normal way, and to extend credit to our Allies for the silver taken in terms of gold, for they will pay us if our world is not shattered in its struggle with savagery, and we can even bank on that indebtedness and convert the debt into a liquid asset—which is not very different in principle from the note that a man discounts, adding his own endorsement. In that way we shall know more nearly where we stand and where we are likely to go in our effort to solve the difficulty.

DISCUSSION

Gold and Credits

The Editor:

Sir—The following excerpt from Prescott's 'Conquest of Peru' is a striking example of the economic effect of a sudden addition of a large amount of gold and silver to the money in circulation. When it is realized that a 'peso de oro' had a purchasing power of perhaps \$15 in normal times of a few years ago, the picture we must form of the conditions at Cuzco becomes impressive. Prescott writes: "The effect of such a surfeit of the precious metals was instantly felt on prices. The most ordinary articles were only to be had for exorbitant sums. A quire of paper sold for ten pesos de oro (approximately \$150); a bottle of wine for sixty; a sword for forty or fifty; a cloak for a hundred—sometimes more; a pair of shoes cost thirty or forty pesos de oro; and a good horse could not be had for less than twenty-five hundred; some brought a still higher price. Every article rose in value, as gold and silver, the representatives of all, declined. Gold and silver, in short, seemed to be the only things in Cuzco that were not wealth."

In this instance the medium of exchange consisted of gold and silver, and is comparable in a degree with a great increase in gold and silver in a modern community. However, there is this difference, that today our medium of exchange consists not only of gold and silver, but also of currency, checks, and the less common commercial paper. The different forms of paper money being known as 'credit money.' The increasing cost of commodities today is commonly stated to be caused by the increase in the quantity of gold. No doubt this is true, provided there is no increase in the use of checks and currency, and provided also that there is no decrease in the quantity of commodities. Also the medium as a whole must maintain its former speed and not be accelerated, for the exchange-value of a medium is dependent not only upon quantity but upon speed of circulation. The foregoing remarks should show that the increase in prices may be due to many causes, and the increase due to gold can be only in proportion to the relative quantity of the gold in circulation, that is, to the total currency in circulation. It follows, therefore, that a curtailment of the currency, checks, or commercial paper, would serve the same purpose as the restriction of gold.

The question of restricting the gold supply is not only one of stabilizing prices but also of conserving the labor used in its production. It is an open question, however, whether it is wise to seriously cripple an established in-

dustry, which in all ages has been one of the main sources of the wealth of mankind. We are all familiar with the common statement that gold is unnecessary, and that some form of credit-money, backed by responsible governments, would answer the purpose as well. But will it? Paper issued by the Russian government five years ago, and backed with all its resources, would seem to have been strong security, but what would be the value of that paper now? The German government today is solvent, but would its paper be as freely acceptable in the United States, or in many other countries, as German gold? The truth is that humanity has found, through the experience of untold ages, that gold is the surest reliance. It requires no collateral. The stamp on its face may be obliterated, the coin melted, sold as bullion, re-coined, and the stamp of another government impressed upon it; and throughout the whole process the value is there and at any time is easily convertible into other commodities. In these facts we find the real basis for the use of the precious metals for money. As far back as the dawn of history, gold has been the medium by which one man's products have been exchanged for another's. It has been found necessary, not only in higher civilizations, but in the very beginnings of primitive culture. It has formed a security beside which a United States government bond, or a Bank of England note must take second rank. The prejudice of mankind for the precious metals is no accident, it is the outgrowth of experience gained through the vicissitudes of time; it is a tending toward a security that has been otherwise unattainable, and which the present world-cataclysm can only serve to reinforce.

The rising price of commodities, as every one knows, has raised the cost of producing gold. This serves as a check upon its production, and will injure the industry even without governmental interference. Furthermore, it is a question whether gold will not in time become as scarce as it is now abundant. The War has made many changes. Suppose the exigencies of the struggle should reverse the flow of exchange, and turn the balance of trade against us. Then we will be obliged to settle these balances in gold, and we will realize that gold is the cornerstone of exchange.

It must be evident that interference with the gold-producing industry should be allowed only in the case of clear necessity and after the most careful scrutiny. It is indeed difficult, if not impossible, to foresee the ultimate effect of an interference with the natural course of industry. In a recent periodical, I read of a manu-

facturer of print-cloths, in an Eastern town, who had been grievously injured by the recent tariff law which increased the duty on imports of ivory. It appears that a large part of his goods were sent to Africa, and that payment was made in ivory. The duties made the importation of the ivory unprofitable, thus making the former direct exchange an impossibility, with the result of destroying that print manufacturer's business. This serves to show how difficult it is to foresee the effects of meddling with the delicate affairs of business.

CHAS. A. PORTER.

Kingman, Arizona, February 6.

Nickel-Copper Steel

The Editor:

Sir—I am sorry to have given the Royal Ontario Nickel Commission credit for the instigation of Alfred Stansfield's research, in my article 'Nickel-Copper Steel Direct from the Sudbury Ores,' when it really belonged to G. M. Colvocoresses. Dr. Stansfield contributed three papers to the report, namely, 'Production of Nickel-Copper Steel from Sudbury Ore,' 'Experiments in Making Nickel-Copper Steel' (which was the investigation of Mr. Colvocoresses' patent), and 'Production of Nickel and Nickel Alloys in the Electric Furnace.' Immediately under the title of the last three there is a note that reads: "This paper was prepared in response to a request from the Commission, and should be considered as an addition to Dr. Stansfield's memorandum dated 18th January, 1916. See page 38." As there was nothing stated to the contrary, I concluded that this note applied to the three papers by Dr. Stansfield, instead of to the first and last only, hence my error, for which I tender an apology to Mr. Colvocoresses. The error, however, has had the advantage at least of eliciting some exceedingly interesting facts from Mr. Colvocoresses.

F. H. MASON.

San Francisco, February 2.

The Editor:

Sir—The interesting article by F. H. Mason, in your issue of January 12, aroused lively memories, as I had pursued the same subject, years ago, but not to such a successful issue.

In the year 1890 or '91 while working on mixed sulphide ores at Leadville, using the roast-magnetizing method followed by magnetic separation, I also made tests on samples of Sudbury ores, obtained from the secretary of the company, a Mr. Macintosh of Cleveland, Ohio. I soon discovered that the magnetic separation on this Canadian ore was incomplete, that is, the nickel and copper remained in commercial quantities in both heads and tails, but the magnetic heads were much richer in nickel and lower in copper. I then roasted the non-magnetic tails and again made a magnetic separation, obtaining a high-grade iron-copper-nickel concentrate. I applied for a patent, including in the patent

application the further use of one or more of the products for the manufacture of nickel-steel along the lines of the work described by Mr. Mason.

I have lost all the data, patent applications, etc., in the San Francisco conflagration, so cannot now give dates. My object in writing is the suggestion that by some such method of concentration a suitable grade of material might always be made available for doctoring a charge in any way desired, the first magnetic concentrate would be high in nickel, and the roast-magnetic concentrate high in copper and iron.

JAMES W. NEILL.

Pasadena, February 6.

Missed Holes

The Editor:

Sir—In your issue of December 1, 1917, there is an inquiry from a Mr. Harrington of Chloride, Arizona, concerning his difficulties from 'missed holes' in shaft-work.

It is not my intention to re-open the entire subject of this not unusual trouble in mining operations, but I would like to suggest a method of water-proofing the joint between the fuse and the cap that I used with marked success in shaft-sinking operations at Cripple Creek, Colorado. The method is simple, the water-proofing being ordinary beeswax. The wax is warmed until it is soft enough to work readily and is then molded around the joint between the fuse and the cap. The result is an exceptionally tight and clean joint. Beeswax is clean material to handle and has none of the messiness that goes with some water-proofing substances; also it can be used rapidly, only a short time being required to prepare a set of fuse.

From my own observations I would say that the great majority of missed holes are caused by water-proofing with the orthodox substances such as soap, grease, etc., which even when used with extreme care often allow the water to get into the cap. Beeswax has none of the disadvantages common to these materials and a trial will quickly convince one of its merit.

WILLIAM SPENCE BLACK.

Arlington, Mass., January 28.

The Editor:

Sir—In regard to the causes of misfires, which have lately been discussed, following the query of J. F. Harrington, I would state that a cause of misfires, and one that is frequently overlooked, is the careless and hurried tamping of holes, whereby a fuse is injured, sometimes by the tamping material, and again by using too large a stick, which is liable to force a portion of the fuse down with the stick, doubling it up with the tamping material. Injury to the fuse is more likely to cause a miss when the hole is wet or partly wet, or when small rocks accidentally get into the hole while tamping

A small sharp rock jammed against the fuse is likely to cause a miss, especially if the hole is wet.

ALBERT F. STONE.

Callahan, California, February 2.

Flotation Physics

The Editor:

Sir—It seems necessary to make some further comment on the theory of electric interaction on the surface separating a conductor from a non-conductor. In a letter appearing in the discussion columns of your issue of November 10, signed by J. A. Block, certain points are brought to issue. His statements will be taken in order.

He says that native copper and silver have been found almost impossible to float, unless filmed with sulphide. May this not be owing to the ease with which these metals are tarnished? O. C. Ralston* states that freshly precipitated copper is easily floated although in a minute state of subdivision.

The adhesion between grease and diamonds and the slight preference of sulphur for oil might still be due to exceptional exhibitions of molecular surface-tension. There is every reason to believe that such surface-tensions have their effect in flotation, though in a minor way. The surface-energy calculations of Clerk Maxwell give a firm theoretical basis for such a belief.

The statement that the latent charge on the surface of the conductor is exactly the same and opposite in sign to the residual charge in the interior of the conductor may be correct, presuming that the outside of the particle is grounded. To be strictly correct, however, we should probably say that the combined charges in and on the particle and the grounded electrolyte immediately surrounding it may be summed to zero. Such an understanding disposes of the apparent repudiation of an electro-static theory made by F. A. Fahrenwald,† because his experiments only pricked the bubble that buoyed up our hopes of differential flotation by electro-static means. These experiments did nothing to affirm or deny the possible flotative effects of the electric differentiations, which we know perfectly well to be existent at and near interfacial surfaces. Electrolytes themselves act like diluted metals and evolve a voltage difference at and near air and solution interfaces. This voltage difference is small compared with that of metal surfaces, but it may have its modifying effect on flotation.

The statement is made that the ordinary laws of electro-statics do not apply at molecular distances. While we have to be satisfied with only the most vague idea of the internal composition of an atom, and it may not be that the ordinary laws of electro-statics apply there, we are much better informed about the phenomena external to the atoms and to which the electro-static laws do apply. The whole ionic theory as de-

veloped by Arrhenius has to do with electro-static charges and their attractions and repulsions, and the science of electrolysis may be said to be founded upon that theory. Owing to the great size of the unit-electron charge, the actions are not of necessity confined to "molecular distances." Such is the amount of energy stored in the atom that we may be sure that there we have to do with a different order of magnitudes. The hydrogen atom, for example, may contain a thousand electrons strained into its small capacity, but a single free unneutralized electron, among a billion hydrogen atoms, would constitute a considerable density of electricity.

Was it not Sir Humphrey Davy who first tried to show an exact connection between the surface-tension and the intrinsic cohesive stress existing in a liquid? As the former is measured per unit-length and the latter per unit-area the two measurements cannot be connected unless factors involving the size of the molecules are also taken into consideration. In the same way we might, with some assurance, presume that there would be no electric surface-tension, as we have called it, if electricity were an infinitely divisible fluid. We cannot say exactly how the electric surface effect is brought about, but there is hardly any way in which we can imagine electrons in motion in a conducting body, without there being a modification of that motion at the surface of the conductor, and therefore a change in the 'condensation' of the electricity, that is to say, a change in the number of free unneutralized electrons within a given space. The cause of the motion may be the internal heat in the body, which heat is also related to the molecular and atomic motions.

The latent charge of the surface of metals is already known to affect chemical affinity, through the medium of electrolytic and allied actions, and it remains to be seen how far flotation adhesions may be also so affected. This would seem to suggest a promising field for an intelligently conducted line of experiments, and if the relation suggested were thereby established, it would not only settle this question but would form the thin edge of a wedge which would go a long way toward the establishment of flotation as a science.

X.

Washington, December 5.

[The writer of this letter failed to attach his name to it, therefore we regret to have to give it anonymous publication.—EDITOR.]

In Camp

The Editor:

Sir—Arrived here on schedule time Monday morning, the 7th, about 10 a.m., and by noon I had been assigned to quarters and established my belongings. At 1 p.m. I fell-in with the rest of the recruits and was marched out to the drilling-grounds where I spent the rest of the afternoon doing squads right and squads left, so you see when they once get you here it does not take them long to get you busy.

*"Flotation," Rickard and Ralston, p. 104 (1917).

†M. & S. P., March 11, 1916.

THE DAY. Get up at 6:15, answer reveille at 6:30 a.m., which is followed by breakfast. 7:30 a.m. we fall-in and are marched to the drilling-grounds, where we are instructed in drilling and are put through setting up exercises and back to our barracks by 11 a.m. From 11 to 12 a.m. clean-up for dinner. Dinner from 12 to 1:30 p.m. At 1:30 p.m. we fall-in again and are marched to the drilling-ground, where we get more drilling and finish up with a hike of from 4 to 6 miles. We are back to the barracks by 4 p.m. From 4 until 5:30 p.m. clean-up for supper. At 5:30 p.m. we stand retreat. At 6 p.m. we march to supper. After supper we are allowed to go any place we want to within the lines (providing your regiment is not quarantined, which is our case now. The 27th has been quarantined since the first part of December, but they expect to lift the quarantine in about 10 days) until 9:45 p.m. and at 10 p.m. we are supposed to be in bed so as to be in shape for the morrow.

THE BARRACKS in which we are living are two-story wooden buildings about 80 ft. long, 35 ft. wide, and 10-ft. ceilings. There are about 35 half-size iron beds on each floor, on which we have a straw mattress and four Army blankets. The first night I spent most of the time trying to keep myself covered up, but it doesn't take long before you learn to lie quiet. There are plenty of windows, but the nights have been pretty cold, so the men would rather have them shut; however, we have had ours open above our beds and have managed to keep from freezing up. In the centre of each floor is a large stove that burns hard coal when we have it, otherwise green wood. This camp-site was covered with small trees, so there is plenty of wood.

MESS-HALL. One-story wooden building about 125 ft. long, 25 ft. wide, and 10-ft. ceiling. Each mess-hall is supposed to accommodate one company, or 250. They have done away with individual mess-kits during this cold weather, and instead everything is placed on the tables in very much the same manner as a mine boarding-house is run. At present we have about 400 men in this regiment, and only one mess-hall, so that it makes things bad. After the first bunch of men have been fed, 150 plates, cups, knives, forks, and spoons have to be washed before the second bunch can come in to eat. That is not the worst feature, however, as the stove they have is only large enough to take care of 250 men, so, in order to take care of 400, all side-dishes have to be cut out. The men are complaining of the food they are handing out, and they often have good cause, because the food runs out before the second table gets all they want. This, however, will be remedied when we move to new quarters, which will probably be this week. As long as one has money he need not go hungry, as one can buy most anything you want at the exchanges. Exchanges are small stores run by different regiments and the proceeds of which go to the mess-hall for extra good things to eat. The 27th so far has no exchange.

THE MEN. As one would expect, we sure have a Duke's

Mixture here. In one bed lies a tough Butte miner and probably in the next a Gen. Mgr. The last three days have brought in a mighty fine bunch of men. They all look like men of means and ability. The quarantine was too much for some of the miners, so New Year's day eleven got through the lines and went to Baltimore for a big time, and I guess they had it. They didn't come back for a week, and, of course, when they did they were court-martialed and sentenced to four months at hard labor with half-pay. So now we do not have to chop our own wood any more. One would think that a sentence like that would make a man feel just a little blue, but not for those boys, they are the happiest lot in camp.

K. P. means Kitchen Police, it means waiter and dishwasher. Each day 7 men are assigned to K. P. duty. Last Friday was my first. You go on duty at 6:30 a.m. and if you work good and fast you can get through by 7:30 p.m. The 7 men are divided as follows: Four are assigned to wait on tables and wash all dishes, two are assigned to the kitchen to wash all pots and kettles, and the seventh is assigned to chop wood for the kitchen-stove. That was my job, but on account of the prisoners chopping all the wood, I scrubbed out the refrigerator from stem to stern and helped to cut up the beef. This is the kind of duty that makes the boys wonder why they left home. This is the remark that I hear 50 times a day: "If I ever get out of this, they will never get me again"; however, some of the boys who made this remark a few days ago are gradually changing their mind, as they see that all these things are necessary for success.

I was very much surprised to arrive here and only find 350 men in the Regiment, but I understand that Major Perry is in Arizona now getting recruits.

Am feeling fine and in the best of health.

Remember we are always glad to get news from Home.

Ed.

Camp Meade, January 13.

MOLDED BLOCKS of gypsum plaster can be used in arid climates for exterior construction. They are so used in Bighorn Basin, Wyoming, and at Douglas, Arizona. The blocks are made of uniform size, hollow, and with smooth sides except the face to be exposed, which may be smooth or molded to represent rough-dressed stone. Warehouses, garages, and other simple structures in Douglas, Arizona, are built of hollow gypsum blocks 8 by 12 by 24 inches. Such gypsum-block structures are estimated to cost one-quarter less than brick buildings of the same design. On account of the size of the blocks the walls can be laid faster, and less skilful labor can be used.

GYPSUM PLASTER is used at some copper smelters as a binder for concentrate and flue-dust. It is mixed with the flue-dust and sacked. The plaster sets, making the contents of the sack a solid block, which is sent to the furnace for recovering the metals originally carried away in the flue-dust.

The Apache Trail, Arizona

By T. A. RICKARD

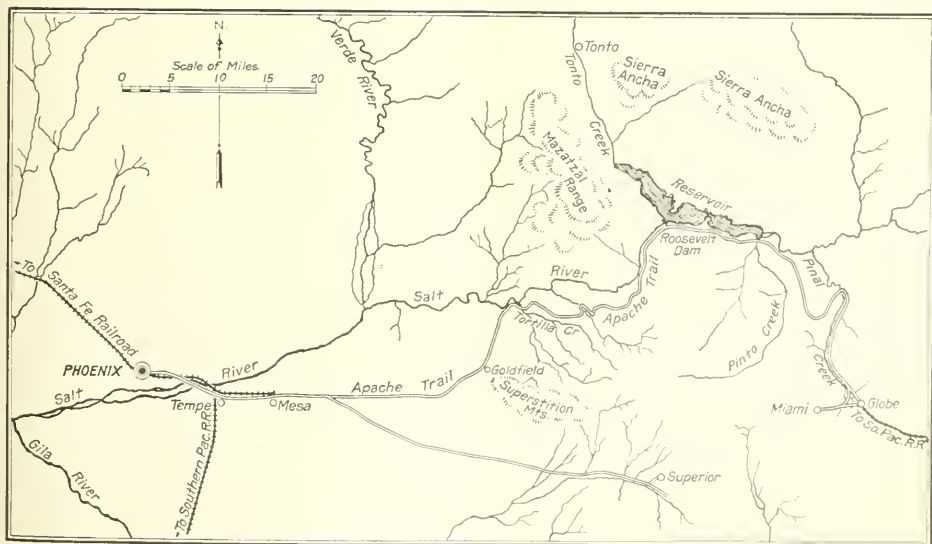

The road between Globe and Phoenix, in Arizona, is called the Apache trail because it follows the track used by the original inhabitants and possessors of this region.

On a sunny morning last May I had the pleasure of traveling with Messrs. J. Parke Channing, B. Britton Gottsberger, and D. G. Scott, from Miami, past the outskirts of Globe, to Phoenix. It seems worth while to record the experience for the sake of those that know the road and to whom therefore my notes will serve as a fillip to their own memories, and for the sake of those to whom this celebrated road is unknown, to whom therefore may come the pleasure of an awakened imagination.

It was early in the morning when we started; the air had the freshness not only of dawn, but of dawn in an arid and spacious country in which the air is uncontaminated by human industry. I was reminded of a similar morning 23 years earlier at Tucson, when I had to take the overland train at 4 a.m. and felt the stimulus of that same invigorating atmosphere. The memory of it was fixed by an incident on the train soon after I had gone aboard. Only one section was vacant in the pullman, so I made use of it. A few minutes later a distinguished looking old man (he seemed 'old' because he was about 25 years my senior) emerged from the berth across the aisle and asked if he might place his bag on the vacant seat opposite mine. Looking at the bag I saw

the name 'T. Sterry Hunt' inscribed on the leather. I knew that Thomas Sterry Hunt was dead, so I remarked that I had recently read a book of chemical essays by a man having the same name. Whereupon my fellow-traveler said: "He used to be my partner." "Then," said I, "you must be Professor Douglas." "Yes, I am Mr. Douglas," he replied. When, in return, I gave my name, he asked me which Rickard I was, and, on being told, he referred in a kindly way to my father, whom he had known many years previously. That was my first meeting with James Douglas, on whom no prefix of Doctor or Professor can bestow any increase of honor.

As the motor-car bowled along the broad concrete pavement connecting Miami with Globe I thought of my honored friend and hoped that he might be spared for many more years of usefulness—for I knew that he had been ill recently. The bracing sunlit air, not yet hot, and still free from dust, recalled another scene in a region far distant. When Scott Turner and I arrived at Dawson, in the course of our journey down the Yukon, ten years ago, we reached the Regina hotel at 6 o'clock in the evening. It was July; in that northern latitude there was no sign of sunset even so late in the afternoon. Soon we were sitting at a table by the open window enjoying a meal that was all the more appetizing by contrast with our experience on the river-steamer from

MAP SHOWING THE APACHE TRAIL, FROM GLOBE TO PHOENIX

White Horse. Again came that delicious feeling of dawn. The air was fresh without being cold, it was as pure as at the creation, for it came across the Arctic snowfields. There was nothing worn or second-hand about it. It made one feel as if "the world was young and life an epic." The memory of it is vivid to this day, and is heightened by recalling the fact that my friend Turner is one of those that survived the sinking of the 'Lusitania.'

The motor-car sped over the Miami flats, passing close to the cultivated tract on which the Miami Copper Co. is trying, not unsuccessfully, to grow those food-products that are at least as necessary as metals for the conduct of the War. We passed the pumping-plant, where the old Dominion mine-water is brought by four miles of 14-in. wooden pipe to a reservoir made by an earthen dam, to be pumped thence to the Miami mine, at the rate of 2,000,000 gal. per day, through another four miles of 14-in. pipe, the lower part steel and the upper part cast-iron, against a pressure of 620 ft. As a reserve, two wells are equipped with submerged centrifugal pumps, each driven by a 100-hp. motor able to pump 1500 gal. per minute. The first time this reserve water was used the pipe-line was ruptured by the breaking of lugs at the joints, owing to the sudden contraction caused by a 20° difference of temperature. Now the well-water is diverted to the reservoir or it is raised by one side of one pump so as to reduce the temperature slowly. The breaks made in the pipe-line were due, in part, to the fact that the upper portion was made of cast-iron. Obviously cast-iron is not to be recommended for such a purpose. I might describe the electrical equipment—for the pumps are driven by electricity—but technical details are out of place in this article, which is intended to be as easy as a joy-ride across the desert.

Turning northward from Globe the road passes by a field of barley, the tender green of the young grain contrasting gratefully with the desolate mountains in the background. A covey of quail crosses the road. Animal life is not wanting. Gophers, rabbits, lizards, and ground-squirrels are seen at intervals. We reach the divide between Pinto creek and Pinal creek at an altitude of 3980 ft. Ahead are the Four Peaks, which remain in sight all the way to Phoenix. A few yards beyond the divide we catch a glimpse of the horse-shoe lake made by the Roosevelt dam. Descending the slope we traverse a natural garden. The desert is in bloom. The palo verde with yellow blossoms, the flaming flower of the ocotillo, the tall column of the sahuaro surmounted by a white cluster, the red and yellow of the prickly pear, and the purple of an opuntia cactus furnish a feast of color, but no fragrance—that belongs to moister air. To the north is the Sierra Ancha, showing a pine forest silhouetted on its crest. From there came the timber for the big dam. Along the divide granite appears, with patches of diabase. The excellence of the road is related to the petrography, for the granite by disintegra-

tion and by the cementing action of rain on the kaolinized feldspar makes a splendid traction surface. Lower on the Pinto water-shed the road cuts through Gila conglomerate, reminding one of the Miami geology. Against the sky stands one of the towers of galvanized lattice-steel that carry the wire by which electricity (under a pressure of 44,000 volts) is transmitted from the Roosevelt dam to the Inspiration and Miami copper mines. The power-line is of the suspension type of construction. Six lines are carried: two lines of three wires each, two ground wires, and two telephone lines. A lark lifts his voice in song. He utters the same triumphant note here in the desert as over the Sussex meadows. The vast perspective of the Arizonan landscape disappears as in a cinema and I see the sandy foreshore of Deal; underfoot I feel the turf of a perfect golf-course, in the offing are fishing-boats, ahead is a little flag set in a circle of velvet green, the voice of a friend comes to me, and overhead the same meadow-lark carols the song he has carried across the world.

As we descend the hill the accelerating car draws the road under it like a ribbon gathered on a reel. A buzzard lifts himself on heavy wing; an oriole flits through the brush. We can see the edge of the lake made by the dam and one or two ranches beside the rivulets that feed it. Crossing Pinto creek we find a camp of the State Highway Commission, which is engaged in building a concrete multiple-arch bridge across the dry bed of the stream. Our New York engineer expresses the opinion that such a bridge is quite unsuitable, because a rush of water comes down the creek twice yearly, and the foundations of the bridge should be deep in order to be secure; a pile-bridge might serve better.

Emerging from the creek-bottom we discern cliff-dwellings in the face of a rocky hillside to the left. By aid of a field-glass the details can be observed. These ancient habitations are placed in a cave under an overhanging cliff of rhyolite—not that we can determine the petrography at this distance! The overhanging cliff protected the dwellings from rain and made them easily defensible against an enemy; they are built of flat stones plastered with mud, the ceilings being made of clay reinforced by small sticks.

These cliff-dwellings were among the marvels that caught the eye of the *conquistador* when he broke into this part of the North American continent. The first white man to penetrate what is now Arizona was Alvar Nuñez Cabeza de Vaca, the leader of a party of five Spaniards abandoned in Florida by the expedition of Pamfilo de Narváez in 1538. Nuñez, marooned in the swamps of Florida, decided to find his way to Mexico overland and led his little party westward across the Mississippi and the Arkansas into what is now New Mexico, eventually reaching central Arizona, whence, after many perilous adventures, he rejoined his compatriots at Culiacan, in Mexico. Nuñez and his companions told highly colored stories about the Seven Cities of Cibola, meaning the Zuñi villages, and thereby aroused

OCOTILLO AND OPUNTIA CACTUS. THE FOUR PEAKS IN THE BACKGROUND

APACHE INDIAN WICKIUP BESIDE THE ROOSEVELT LAKE

the cupidity of the Spaniards and the religious zeal of their padres. Early in 1539 one of the latter, Marco de Niza, led a small expedition from Culiacan to the supposed Seven Cities. This missionary traversed Arizona and set up the emblem of Christianity, calling the country the New Kingdom of San Francisco, a name that still clings to the range of mountains separating the Verde from the Colorado river. The padre returned safely to Culiacan and capped the story of Nuñez with his own yarns about a marvelous country to the north. In April 1540 Vasquez de Coronado led a bigger expedition, mostly Mexican Indians, into the Pimeria, as the region was beginning to be called. Coronado passed northward along the valleys of the San Pedro, the Salado, and the Verde, reaching the Zuñi villages in 45 days after his start from Culiacan. He found that the rich and populous cities described by his predecessors were only insignificant groups of stone and mud dwellings tenanted by quiet and industrious Indians possessing no treasure of gold and ignorant of mining. Both Nuñez and Coronado saw the wonderful ruins of Casa Grande and many other cliff-dwellings in the course of their explorations. The first mineral wealth disclosed in Arizona was the silver ore found in 1582 by Antonio de Espejo at the head of the Verde river in the district now known as the Black Hills.* In 1847 all of Arizona north of the Gila river was ceded to the United States by the treaty of Guadalupe Hidalgo and in 1854 the southern portion was acquired from Mexico under the Gadsden purchase. The name 'Arizona' is of dubious origin. By some it is said to be derived from *Arizuma*, a name said to have been used by the early Spaniards. The most likely derivation is the Spanish-Indian '*arizonac*,' meaning 'few springs.' This was the name of an 18th century mining settlement in the Santa Cruz valley just south of the present border of the State.

Near Tempe are mounds containing the ruins of ancient dwellings that must have been as imposing as those of Casa Grande. Lines of a canal can be traced from the ruins to the bank of the Salt river, suggesting how water was brought to this pre-historic pueblo. Indeed the wide valley of the Salt river and the spacious plain separating it from the Gila valley contains so many remains of dwellings and canals as to indicate that this region was once thickly inhabited by an industrious and intelligent people.

The origin of these habitations was imputed formerly to an extinct race, but it is now believed that the cliff-dwellers in the region covered by parts of Colorado, New Mexico, and Arizona were the immediate ancestors of the Pueblo Indians. They were so named by the Spaniards because they lived in villages, instead of roaming wild; they were the semi-civilized, sedentary, and agricultural tribes, now best represented by the Hopi and the Tewa, whose villages still crown the tops of many mesas. These gentler folk made their homes under the beetling cliff in order to protect themselves against the

wilder Navajo and Apache tribes. In French the word Apache has become the synonym of deviltry and it is a fact that this tribe was the last to submit to the white man's domination. At the close of the 18th century in England the word Mohawk, the name of an Indian tribe then inhabiting the State of New York, was employed as a synonym for bands of lawless or rowdy persons.

At the beginning of the Civil War the withdrawal of Federal troops gave the Apaches a chance to break loose and they made the most of it, marauding the country so that all mining enterprise was stopped. From 1863 to 1874 the history of Arizona is an ensanguined record of the stubborn fighting between the incoming settlers and the belligerent Indians. In 1874 General George Crook subdued the Apaches and placed them on reservations. The Apaches were conquered, after much fighting, by General Nelson A. Miles in 1886, their last stand being made in the Chiricahua range, where they surrendered, to be deported to Florida and Alabama. About 5000 Apaches now occupy reservations in Arizona. This race comes from the frozen North; it is of Athabaskan stock; on migrating to the warm southland the Apache developed the fighting habit. Among the most belligerent were the Tonto Apaches, who live along the stream of that name feeding the Roosevelt dam. It is worthy of note, however, that the Apaches practised irrigation before the white man invaded their domain. They impounded the stream and built canals plastered with clay. As we shall see, the Indian and the beaver alike had notions of dam-construction long before the Reclamation Service came to the aid of the settlers in the Salt River valley.

The road now approaches the lake, which it follows. It is good to see such a body of water in a dry region. One of our party enquires after trout, whereupon another recalls the story that George W. Maynard used to tell of a Washington official that wrote to the Secretary of the then Territory of Arizona enclosing a blank for fish statistics. The Secretary scribbled across the blank: "Last known fish in Arizona was seen twenty years ago going up Hassayampa creek with a canteen under his fin looking for water." That, of course, is a libel. Nowadays people come from afar to fish in the Roosevelt lake, where black bass weighing six and seven pounds are caught; also carp.

As we turn a sharp corner the outlet of the lake and the dam itself come into view. Alongside the road, between it and the water, one sees the concrete channel or ditch that supplied water for the power used during construction. Above the road a group of pretty houses and a rose-hedge in bloom mark the quarters of the local representatives of the Reclamation Service. On the hillside to the left of the dam the cement plant employed during the construction period looks like a cliff-dwelling when first seen. Across the dam another group of buildings marks the former site of the contractor's camp. The Southern Pacific Company has a hotel at the water's edge. Tents along the shore of the lake suggest camping parties, attracted hither from the mining settlements

**The Resources of Arizona*, by Patrick Hamilton, 1833.

TONTO CLIFF-DWELLINGS

THE BRIDGE AND THE LAKE ABOVE THE DAM

The distance from Globe is 40 miles, and from Miami 44 miles. From the dam to Phoenix is 78 miles.

The Roosevelt dam was designed to reclaim 240,000 acres of arid land. The first stone was laid on September 20, 1906, and the dedication by Mr. Theodore Roosevelt took place on March 18, 1911. The site was in the heart of a wilderness, 62 miles from the nearest railway, at a place where the Salt river had eroded a narrow gorge that could be blocked advantageously. The first thing done was to build a good wagon-road, at a cost of \$300,000. Then power had to be provided for the contractors. This was accomplished by building a small concrete dam across the Salt river at a point 19 miles up-stream. There the water was diverted and conducted along a cement-lined ditch to a point just above the dam-site, where it dropped 220 ft. on turbines that generated 4000 horse-power. Next a mill had to be built for the making of cement at the rate of 500 barrels per day. This mill supplied 340,000 bbl. of cement at a saving of \$600,000 over the lowest bid offered outside. Owing to labor shortage, due to the heat and the remoteness of the locality, the engineer in charge availed himself of the Indians, who proved excellent workers and acquired habits of industry that have fitted them for employment on railroads and other later enterprises in Arizona. The rock for the structure came from the sandstone of the canyon. The dam is 280 ft. high; the base is 168 ft. thick; it is surmounted by a roadway 16 ft. wide and 1080 ft. long, arched up-stream. In plan the dam forms a quarter-circle, with waste-weirs 200 ft. long at each end and spillways cut in the solid rock. The dam has three openings to regulate the outflow. In the canyon below is a power-plant of six turbines operating a 1000-kw. G. E. 2300-volt 25-cycle generator. Electric light and power are supplied to Phoenix, Globe, and other towns; also to the mines. The reservoir has a storage capacity of 1,284,000 acre-feet.

Below the dam the road climbs along the side of a rugged gorge. Patches of purple granite appear in fine contrast with the sunlit green water. An occasional cottonwood tree lying prone on the bank marks the work of the beavers, who cut them down, by aid of their powerful incisor teeth, to make their dams. One does not know which to admire most, the big concrete structure built by man to impound the aberrant waters or the logs cut down by the beavers, dragged by them to their dam-site, and laid in place with instinctive intelligence. The little rodents carry mud and stones in their fore-paws and drag the timber with their teeth. They work at night and that is why they are rarely observed. Where the water is quiet they make the dam straight across, but where a current runs they curve the structure so that its convexity is up-stream. They are sociable and co-operative little animals; in this respect, as in their intelligence, they set an example to man, of which he has availed himself. The cutting of trees by the beavers in the gorge just below the Roosevelt dam looks like a blunder on the part of the little brown en-

gineers—a misdirected instinct—for the current is too strong and the volume of water too great to permit them to build a dam. They are migrating down the Salt river; perhaps they intend to float the logs to a lower reach of the stream for use there?

Looking back at the great wall of the dam, Mr. Gottsberger remarks that it is unusual for the water to be coming over the spillway so late in the year and he explains that this indicates a slow melting of the snows in the mountains and that the Salt River valley is assured of sufficient water for three years.

The road leaves Salt river and turns along Fish creek into an imposing rocky gorge that shows no outlet until a sharp bend has been turned. Our car, an 8-cylinder Cadillac, took the Fish creek grade on second. But that was less wonderful than the rocky battlements and stone terraces that framed the gorge where far below the blue of the river threaded its insistent way. How long did it take to cut that valley? Nay, how much longer did it require to accumulate the sediments and to pour the lavas that make the substance of these mountains? The geologist tells us that the patient forces of erosion—the expansion and contraction due to the difference of temperature from day to night—the cracking by frost, the blistering by the noonday sun, the washing by snow and rain, the grinding by the blown sand—these persistent atmospheric agents sufficed to carve the ravines and sculpture the mountains. The average man accepts the explanation as a fine piece of scientific reasoning, but it leaves him more admiring than convinced. The failure to appreciate the explanation is due in the first place to the fact that nature usually works unseen; the falling stone and the riven rock are rarely watched because the work is done at dawn and in the twilight when the changes of temperature are most marked. When the storm is at its height, man goes indoors for shelter and lets nature do her worst unobserved. Near the Apache trail, at Mormon flat, the traveler can see a white scar on the face of a cliff where a bastion of rock was blasted eleven years ago by a thunderbolt. The engineers in our party guessed at the weight of the fragments lying on the talus at the foot of the cliff; between 6000 and 10,000 tons. Such an act of destruction is rare as measured by the observation possible within the span of human life. Time is of the essence in geology. Nature has been given a blank check on the bank of Time; to man, as to a vagrant ant, the periods of geologic operation seem immeasurable. We take a thousand years as a unit and therewith measure the time since the first trace of man appeared on the earth's surface, but that was the last minute of a day that began in the dawn of a remoteness beyond our reach. At the theatre they drop the curtain between two scenes "to mark the passage of time," a day or a year, as the text of the play may require. Our geologic periods are like those brief intervals on the stage; they are merely suggestions of the aeons that have passed like the shadow of a cloud upon the snow.

The road up the Fish creek divide might well intimi-

THE PAINTED CLIFFS, FROM THE APACHE TRAIL

THE ROOSEVELT DAM

dance an inexperienced driver. The story is told of a man that was driving a light touring-car and found that his brake did not work properly because he had no weight over his back wheels, which skidded repeatedly, until he was in a state of nervous collapse. He stopped the car and walked to the nearest road-house. The man sent to fetch the car had to throw stones in the rear of the chassis in order to correct the effect of the grade. Mr. Scott told us how he overcame this trouble by taking two or three gunnysacks and loading them with sand to serve as a counter-balance.

Fish creek is one of those contrary names so common in the West, what the academic term '*lucus a non lucendo*,' a grove being given a name derived from the Latin word for light, although a grove is a dark place. From the fishless creek the road crosses Tortilla flat and much of it is on bare rock requiring careful driving. The traffic is light. Long teams with jerk-line drivers are a thing of the past. We passed motor-cars in groups of three, these being the modern equivalents of the old leather-thoroughbrace stage-coaches. One of the motor-stages had a trunk tied outside so as to endanger a passing vehicle. This is against the State law, by which no public vehicle may carry anything that projects beyond the footboard. We met a wagon and a trailer loaded with boards for the building of a house. The front end of the trailer's load was bumping into the lumber on the leading wagon so as to smash the ends of the boards and necessitate a fresh sawing to make them fit. It is better to be sure than sorry. In the course of the journey as far as Tempe, where local traffic begins, we met six wagons and 18 motor-cars.

Emerging into more open country the Superstition mountains are silhouetted against the western sky—a grand mass of rock surmounted by pinnacles like tombstones. The name 'Goldfield' inscribed on a post marks the scene of mining, indicated further by a couple of dumps. It is not clear whether this is the kind of mine from which gold is won or whether it be the kind into which gold is diverted. Both kinds seem to be needed in order to promote human knowledge. The road improves as it enters the expanding valley of the Salt river. One is reminded of the wastefulness of poor roads, particularly in these days of motor traffic, when the vehicles most used represent so large an investment of capital. To a European our road-making seems short-sighted and shiftless, for it is so hastily and cheaply done that it requires continual repairs or, as is more commonly the case, a relapse into permanent disrepair. Against such criticism it may be urged that our mining communities are so ephemeral that it is inadvisable to spend much money in the construction of durable highways. This is not a satisfactory excuse, because most mining centres remain active much longer than the wretched roads built to serve them, and a good road once built contributes not only to the prosperity of the particular district that it taps, but it also affords invaluable assistance in the exploration of the adjacent country. The railroad diminishes the

scope of the wagon-road, but now that motor traction is gaining rapidly in favor and usefulness it is worth while to lay stress on the need for better road-building in our mineral regions. As these ideas come to mind we are speeding smoothly over an excellent surface of granitic débris. A bird flits into a cholla, a peculiarly prickly cactus. Dismounting two of us examine the nest, so thoroughly protected from snakes and owls by the natural spears that surround it.

At the 95-mile post, as measured from Globe, we enter an area of irrigated cultivation. The altitude is 1000 ft. A finger-post points the turning to Superior 35 miles distant, where is the celebrated Magma copper mine, not only a source of copper but the scene of technical research of a high order of usefulness. Soon we are traversing smiling farm-lands. I hear somebody remark that 12 cuttings of alfalfa are obtained in a year! The lyre-bird is not extinct. We approach Tempe, named after that vale under Mt. Olympus in Thessaly whose beauty of landscape and mildness of climate are proverbial. This Arizonan scene is grateful to the eye of those emerging from the barren lands in which copper and gold are mined. The road crosses broad ditches in one of which children are bathing merrily. A school-house among the cottonwoods bespeaks the herald of civilization and the making of good citizenship. Dairies and manufactories of condensed milk indicate the prevailing industry. The road is now crossing a succession of Mormon settlements, thrifty and prosperous.

The population of the Salt River valley includes 4000 Mormons. A few of them are also to be found among the Indians. The chief Mormon settlement is Mesa, through which we passed before reaching Tempe. Mesa was one of the early white settlements in Arizona; it was founded by the Mormons, who have built a number of substantial meeting-houses and community stores. Farms and herds of cattle bespeak the prevailing occupations. They make good citizens, being industrious and sober, keeping to their own affairs as much as possible. Although they have a vote, and take part in politics, they do so chiefly to protect the welfare of their own community. They are good men of business and capable of driving a shrewd bargain; quick and frugal, earnest and faithful to their creed. Mesa is 16 miles east of Phoenix; 10 miles beyond is Lehi, where the Mormon Indians dwell with white settlers in a small agricultural community.

At the 116-mile post, after 9 hours of travel, we enter the environs of Phoenix, and pass four or five miles of villas and bungalows built for the use of wealthy tuberculous invalids from all over the United States. The desert air is softened by irrigation, the climate is genial, if a little hot during mid-summer. I am reminded of Clarence King and Joseph A. Holmes, both of whom came here to fight for life. Holmes had been appointed the first director of the U. S. Bureau of Mines and had established the Bureau as a tower of administrative usefulness in the best interests of the mining industry when he died here in 1915; his hand was firmly

placed on the plough and he was making deep straight furrows across the field of industrial progress when he was summoned to leave the work on which he had set his heart with convincing earnestness. When he retired to Phoenix he still retained his post, hoping to return to it, while the active work was performed by his loyal comrade, Van H. Manning, now his successor. Since Holmes has died sundry well-meaning persons, including several that had done all they could to prevent his appointment to the head of the Bureau, have endeavored to memorialize him by means of medals and by founding chairs of safety engineering, but his monument endures in the work that he did and the organization that he created, both of which promise to preserve his name in unfading honor. The other courageous spirit, Clarence King, was one never to be forgotten by those that knew him. I have referred to the Apaches; it is worthy of note that King was nearly their victim. Dr. Raymond tells how King and Gardiner were engaged in a geological reconnaissance when one day, on the road to Prescott, they had ridden ahead of their cavalry escort. Absorbed in conversation they were surprised by a couple of Apaches, who sprang from the bushes and with arrows aimed at their breasts called upon them to dismount. Gardiner's impulse was to use his revolver, but King restrained him, guessing that these two Indians were members of a larger party. In a moment fifty Apaches emerged from the chapparal and surrounded the two white men. They were compelled to dismount and remove their clothes, in preparation for torture. King realized that the only chance of escape from death was to kill time so that the escort might come to the rescue. So he showed them his cistern-barometer and explained, in Spanish and by signs, that it was a new kind of gun of very long range. Meanwhile the Apaches prepared thongs for their captives and lighted a fire to place on their breasts. They were half-stripped when the cavalry arrived and, realizing the situation, charged immediately, scattering the Indians and saving King and Gardiner unhurt. King was a vivid personality, a chromatic character, a beautiful spirit. At the end of an active, useful, and inspiring life he came to Phoenix, late in 1901, having been attacked by pneumonia after the germs of tuberculosis had fastened themselves upon him during a trip to the Klondike in the preceding summer. He died at Phoenix on Christmas eve, 1901. A keen student and observer, a born teller of stories, buoyant and versatile, sympathetic and intellectual, it is remarkable how little he left in writing, but how deeply he wrote himself on the hearts of his comrades, many of them men distinguished in science and art. His memory enriches Phoenix for all time.

LIME, that is, burned or 'quick-lime', was produced in the United States to the extent of 3,663,818 tons, in 1917, this being 10% less than the production for the preceding year. The consumption of hydrated lime amounted to 719,757 tons, representing a slight increase.

Sulphuric Acid in 1917

More sulphuric acid was produced in the United States in 1917 than in any previous year. A moderate estimate shows that the increase, stated in terms of 60° B. acid, amounted to at least 600,000 tons. It is not yet possible to state accurately the production of sulphuric acid in 1917 according to strengths, for some of the companies that produce 50°, 60°, and 66° acid have reported their entire production together and so stated it as if it were theoretical 100% acid. Now, 100% sulphuric acid is above 66° B. and is here reported as 'stronger acid,' but a certain quantity of the stronger acid reported should be carried as acid having a strength of 66° B. or less. As no data are available to show the proper distribution of all the acid made in 1917, the following table has been prepared as if the reported production were the actual output:

Strength of acid	1917	1919
	Short tons	Short tons
50°	2,306,372	1,829,471
60°	1,187,704	1,119,753
66°	850,006	1,580,100
Stronger acid	1,190,019	443,232

The condition of the market for sulphuric acid in 1917 is reported to have been even better than in 1916, and the value of the product was considerably higher. Some companies have had difficulty in obtaining sufficient sulphur ore and many of them have been compelled to change from pyrite to sulphur burners. Experiments in the greater utilization of pyrrhotite have been carried on and attempts have been made to find domestic deposits of pyrite that can be used if the supplies of foreign ore are curtailed under the conditions imposed by the War. The estimates given above are based on returns from the acid manufacturers received by Philip S. Smith, of the U. S. Geological Survey.

CADMIUM in a suitable proportion has been found to increase considerably the alloying capacity of lead. For instance, if there is added to a quantity of pure lead from 8 to 10% of cadmium and the two metals are fused together, and to the resulting alloy there is then added from 8 to 10% of pure manganese or of a high-percentage ferro-manganese in the molten state, a uniform alloy will be formed, which is distinguished by all the properties characteristic of the high-grade tin-white metals. It is generally possible in this manner to effect the complete absorption of the manganese by the alloy in the course of a single operation. Attention must be directed to the fact that when molten ferro-manganese is employed, little or no carbon will separate, and that both the manganese carbides and the metallic manganese will be dissolved in the other metals forming the alloys, the influence exerted by the carbides being limited to the fact that their presence imparts a greater degree of hardness to the resulting metallic alloys than would be the case were carbon-free manganese employed.

The Amorphous Minerals

By AUSTIN F. ROGERS

*The recent advances in colloid chemistry remove all excuse for neglecting the study of the amorphous state. The application of colloid chemistry to mineralogy has been pointed out by Cornu and others. More recently Mare and Himmelbauer (*Fortschr. der Min., Krist., u. Petrog.*, III, 11, 32, 1913), have given a bibliography of the subject. Most amorphous minerals are hardened hydrogels. The water present is usually considered to be adsorbed, that is, it may have been taken up by the freshly formed colloid through solvation, though this is doubted by Robertson, but, after hardening, the water may exist in solid solution. For example, hyalite opal is apparently a homogeneous substance, and may be regarded as a true solution of water in silica. It is possible, and quite probable, that the mineral hydrogels are not properly colloids, but are of colloidal origin, and it is safe to call them amorphous. Bachmann proved, by means of the ultra-microscope, that the structure of the solid gel is extraordinarily fine. The recognition of colloidal structures in the study of minerals, rocks, and ores is important, and the fundamental differences between amorphous and crystalline minerals should not be overlooked. Also the terms colloidal and amorphous must not be confused. The term meta-colloid, proposed by Wherry for micro-crystalline substances of colloidal origin, is useful. From the standpoint of physical chemistry amorphous solids are liquids. The shape of a liquid, when unaffected by gravity, is spherical; so, hydrogel minerals are often spherical, botryoidal, stalactitic, and amillary in form. The rounded or colloform minerals may be either amorphous or crystalline, while minerals occurring as euhedral crystals may be amorphous alteration products of original crystals, as, for example, malacoon, which is a pseudomorph after zircon. Yttrantalite, thorite, allanite, gadolinite, homolite, and yttroceratite, all occur in euhedral tetragonal, orthorhombic, or monoclinic crystals, yet in many instances the material is optically isotropic, and the amorphous equivalents of these minerals represent pseudomorphs after the original crystalline minerals. Fibrous, lamellar, and some other structures of crystalline aggregates, do not necessarily indicate crystallinity. These may be remnants of an original crystalline condition. Pyrolusite, as one example, is probably an amorphous manganese di-oxide produced by the de-hydration of crystalline manganite. In the absence of cleavage and other direct proofs of crystallinity, optical tests are to be relied on chiefly for transparent and translucent minerals. Many amorphous substances are doubly refractive, especially colloidal crusts, the double refraction here being due to strains developed in the hardening of the gel. For opaque minerals etching is the most satisfactory. C. F.

Tolman recently determined meta-colloidal chalcocite by examining polished surfaces, etched by nitric acid, with the metallographic microscope.

The chemical composition of most amorphous minerals is not as definite as that of the average crystalline mineral. Practically all of them contain water, even if the corresponding crystalline minerals are anhydrous, but the excess of water over that present as hydron or hydroxyl is probably not essential. Thus, myeline is probably the amorphous equivalent of kaolinite, yet it contains practically the same amount of water. Among the better established amorphous minerals may be mentioned the following: amorphous carbon or schungite is a modification of carbon, and is not converted into the yellow scaly substance called graphitic acid, and it is soluble in a mixture of potassium chlorate and nitric acid; amorphous sulphur also occurs in nature; hydrotroilite $[\text{FeS}(\text{H}_2\text{O})_x]$ is a colloidal amorphous ferrous sulphide, found as a black slime in inland seas, and in some moist sands and clays; hydro-cuprite $[\text{Cu}_2\text{O}(\text{HO})_x]$ the amorphous 'tile-ore,' is found as a massive brick-red mineral associated with cuprite, which appears under the microscope as an orange-colored, almost opaque substance, in contrast to the dark red translucent cuprite; hematite presents a crystalline form, and a red earthy variety, such as the o-olitic Clinton ore, and the soft red hematites of the Mesabi range, which are amorphous, and contain a small amount of water; also a new mineral, which I recently identified, and have named cornuite, this being a glassy, green to bluish-green copper silicate $[\text{mCuO} \cdot n\text{SiO}_2 \cdot (\text{H}_2\text{O})_x]$, which is the amorphous equivalent of chrysocolla. Specimens have been found at Globe and Bisbee, Arizona, at Ludwig, Nevada, at Copper Mountain, Alaska, and at Collahuasi, Chile. It appears in colloform bands within layers of colloform chrysocolla. It is softer than its associate, and is more readily soluble in hydrochloric acid. It is probably a solid solution of cupric oxide, silica, and water.

ZIRCONIA as a refractory for lining steel furnaces received some publicity of late. It is said to act as a neutral lining, as compared with silica or magnesite. An interesting development to which less attention has been given is the manufacture of ferro-zirconium. According to an English authority ferro-zirconium has been successfully employed in Germany for the production of zirconium steel, used for armor plate, projectiles, bullet-proof steel, and other purposes. Zirconium steels are stated to be particularly hard, such material, one inch thick, being equal to three inches of the best German armor plate. Before the War the Germans had practically a monopoly of the manufactures of zirconia, which was mainly dealt with under German patents; this state of affairs has since been changed. It is of interest to note that practically every so-called rare element has proved of industrial importance in steel metallurgy, although their influence depends largely on their effect upon the carbon in the steel.

Bauxite Products

By JAMES M. HILL

*The proving of any particular bauxite deposit is accomplished by means of churn-drill holes, or test-pits and shafts. Ordinarily, where labor is cheap, the latter method is to be preferred, as a much better idea of the deposit can be obtained. Samples are taken regularly, and in thick deposits several samples across the face should be analyzed, as the bauxite may vary in composition from top to bottom of a deposit as well as horizontally. In the northern Georgia-Alabama field prospecting is limited to the edges of the red-clay areas adjacent to quartzite ridges, for it has been shown that most of the deposits have been found in these relations. 'Dornicks,' that is, bauxite boulders, and bauxite pebbles are the signs of deposits, and should be searched for carefully. It is more difficult to prove these pocket deposits by drilling and shafts than the fairly regular horizontal lenses, for the distribution of clay and bauxite is irregular in the pocket deposits.

Owing to the presence of variable amounts of clay in all types of bauxite deposits, hand methods of mining appear to be necessary. In a few places drag-line excavators or steam-shovels are employed to remove overburden. The usual procedure in the flat-lying deposits of Arkansas and central Georgia is to strip the overburden for some distance ahead of the face of the ore. A little powder is used to break the hard upper surface of the bauxite. Hand shoveling to facilitate ready sorting of ore and waste is in vogue. In most mines cars run on temporary tracks are used, but in the smaller pits the ore and waste are transported in wheelbarrows. Seepage is ordinarily taken care of by drainage ditches, but in a few places pumps are necessary to keep the working-area reasonably dry. In the northern Georgia-Alabama-Tennessee field the conditions are different, as the bauxite is taken from pits and the work progresses downward instead of horizontally. Inclined shafts are necessary to raise the ore, as very few of the deposits are so situated that open-cuts or tunnels can be used for transportation and drainage.

Most of the bauxite of the Arkansas mines is kiln-dried before shipment, and one of the largest operators in Georgia ships only dried ore. However, a number of operators in the Georgia-Alabama-Tennessee field ship undried or 'green' bauxite. The drying equipment is simple, consisting at most places of a small wood-fired rotary kiln similar to, though smaller than a cement kiln. The bauxite is crushed and fed to the kiln with an endless chain of bucket elevator. The dried material is

elevated to bins for ease in loading wagons or cars. The drying, which takes but a short time, is resorted to in order to drive off the uncombined water, which reduces the weight of the green ore 10 to 15%.

Aluminum is the most important product made from bauxite. Alum, aluminum sulphate, and chloride are the next most valuable. Artificial abrasives are third in point of value at the present time, with the refractories made from bauxite ranking fourth. There is a great difference between the value of bauxite and the products made from it. In 1910 the market value of bauxite used was approximately \$780,000. From this material aluminum valued at over \$7,000,000, and aluminum chemicals valued at over \$2,500,000 were made. In 1916 the difference was even more marked, for the bauxite had a value of \$2,300,000 and the products exceeded \$42,000,000, divided as follows: Aluminum, \$33,900,000; aluminum chemicals, \$5,800,000; abrasives and refractories, over \$2,500,000.

The Aluminum Co. of America is the only producer of the metal in the United States. It has large chemical works at East St. Louis, Illinois, and is now building a chemical plant at Sollers Point, near Baltimore, Maryland. At these plants the bauxite is treated chemically to make alumina (Al_2O_3), which is the first step in the making of aluminum. The aluminum plants of this company are at Niagara Falls and Massena, N. Y.; Marysville, Tennessee; and Badin, North Carolina. At these four plants the electrolysis of alumina to the pure metal is accomplished. The iron pots or retorts, in which this change takes place, are carbon-lined, and are equipped with adjustable carbon electrodes. The alumina is charged into a molten bath of cryolite, a mineral found principally in Greenland, which is a double fluoride of aluminum and sodium. When the electric current is passed through the charge the metal aluminum settles to the bottom of the bath and can be regularly tapped off. The operation is continuous for long periods, provided the operations are carried on properly. The installation of aluminum plants requires large capital, first for chemical works in which to make alumina, and second for the installation of power-plants to generate large quantities of electric energy. Apparently the largest problem in an undertaking of this sort is that of obtaining cheaply the enormous quantity of electric power necessary.

The average open-market price of aluminum for small lots during 1916 was 60.71c. per pound. The contract price ranged from 31 to 37c. Prior to the War the open-market price ranged from 18.63c. per pound in 1914, to 23.64c. per pound, in 1913. Alum, aluminum sulphate,

*Abstract: 'Bauxite in the South,' 'Manufacturers Record,' December 27, 1917.

and aluminum chloride are the chief salts used commercially that are made from bauxite. There are 9 plants making alum, 18 plants making aluminum sulphate, and 5 plants making aluminum chloride, in the United States. With minor exceptions, these are situated in the north. The largest plants are in Pennsylvania, New York, Massachusetts, Ohio, Michigan, and Illinois. In the manufacture of aluminum chemicals the first step is the treatment of bauxite with sulphuric acid to give a solution containing aluminum sulphate. The theory of the manufacture is, on the whole, rather simple, but numerous steps in the process make the technology appear complicated. Apparently close chemical control is required. Alum until 1915 sold approximately at \$31 per ton, but in 1916 the price rose to \$43; for aluminum sulphate the pre-war price was between \$17 and \$19 per ton, and it now sells for \$29 and \$30, and aluminum chloride for \$70. Bauxite abrasives, such as alundum, aloxite, exolon, and lionite, are now being made by four companies in the United States, whereas before the War only two companies were producing these articles.

The installation of plants is largely dependent on the availability of cheap electric power, for the abrasives are made by fusing bauxite in a simple electric furnace. The fused mass is cooled, broken, ground, and sized. The sized material is made into a multitude of different articles, including powder, cloth, stone, and wheels. The average price received for the large output of artificial abrasives in 1916 was a little less than \$70 per ton. It would appear that there is room for a considerable expansion of the artificial abrasive industry. Bauxite refractories, or closely analogous products, are made by several companies in the United States. The crude bauxite is washed and calcined at a high temperature to drive off the combined water. The calcined material is ground, bonded with fire-clay, sodium silicate, or lime, and molded. The shaped articles are dried and burned in down-draft furnaces. The price of these refractories ranges from \$50 to \$380 per thousand, the value being determined by the quality of the product, the bricks consisting of nearly pure alumina being the most refractory. A relatively new development in bauxite refractories is the use of fused bauxite, either in molded form or as ground or pulverized material for incorporation into refractory cements. Of this class of refractories, which are made in electric furnaces, some are pure fused alumina, and are extremely refractory, melting at temperatures of 2050 and 2100° C.

BORAX in this country is used in the manufacture of enamels or porcelain-like coatings for metal utensils, such as bathtubs, kitchen sinks, cooking utensils, and the like. Fully one-third of the normal production is used in this way. Almost a third of the combined production of borax and boric acid is used by manufacturers of other chemicals. Both borax and boric acid are dispensed through wholesale and retail druggists and dealers that supply the domestic requirements, and

these uses account for 25% or more of the whole production. The remaining 10% is distributed among meat and fish packers, manufacturers of glass, tanners, soap manufacturers, and potters. Price quotations show a gradual rise in the price of borax and boric acid, reaching about 7 or 8c. per pound for borax and about 12c. for boric acid toward the close of 1916. Contracts for large quantities of borax were placed during the year for 1917 delivery at 6½c. per pound. In the open market the price for crystals granulated, in barrels, is now 7½ to 8c. per pound.

Phosphatic Oil Shales

In its investigations of richly carbonaceous shales in the United States, made to obtain information concerning shales that may be profitably distilled for their content of petroleum when the oilfields of the country have been more fully exhausted or the prices of crude oil have become higher, the U. S. Geological Survey has sampled and tested shales from deposits of unusual interest in Montana. These deposits are not very thick, and their yield of oil is not greater than that of shales now distilled for petroleum in Scotland, but they are somewhat unusual in that the shale contains a considerable amount of phosphate as well as bituminous matter. A sample of this shale from Muddy Creek basin yielded 7.5 gal. of petroleum per ton of shale and 15.56% of phosphate, and a sample from Smallhorn canyon yielded 24 gal. of petroleum per ton of shale and 2.62% of phosphate. A brief report on these shales, prepared by C. F. Brown, has just been issued as Bulletin 661-I.

THE FOLLOWING data showing exports of metals and ores from Yokohama to the United States, tabulated by George H. Seidmore, consul general to Japan, afford interesting information.

Metals and ores	1916		Jan 1 to Nov. 12, 1917	
	Quantity	Value	Quantity	Value
Copper ingots and slabs, lb.	2,846,066	\$322,746	1,097,600	\$303,656
Antimony, refined, lb.			1,635,864	216,751
Antimony, regulus, lb.			336,000	49,018
Manganese ore, tons.	2,688	86,617	1,918	64,349
Ferro-manganese, lb.			101,331	12,174
Molybdenite, lb.			14,699	31,644
Molybdenum ore, tons.			490	57,399
Ferro-silicon, lb.			24,640	1,785
Scheelite, tons.	196	569,536	85	115,803
Ferro-tungsten, tons.			1	4,985
Wolfram ore, tons.			109	132,409
Zinc-dust, lb.	515,360	95,527	730,675	62,281
Iridium ore, lb.	781	31,871		

It will be noted that Japan is retaining more of her copper, but has responded to the demand for rare metals. The trade in antimony has developed from zero to a considerable figure, and there is some movement of manganese. The Japanese have not wastefully shipped it as ore, but have taken a smelter's profit on the way.

Silver Haloid Salts, Wonder, Nevada

By J. A. BURGESS

*The halogen salts of silver at Tonopah show the chloride, bromo-chloride, and iodide occupying fairly well-marked horizons; their respective positions being downward in the order named. This sequence is explained as corresponding to the order of their deposition from percolating surface waters charged with haloid alkaline salts. It is interesting to find that the arrangement of these secondary silver minerals at Wonder corresponds to that at Tonopah, and bears out the theory advanced to explain the order of deposition at that place.

Wonder is situated in Churchill county, Nevada, about 120 miles east of Reno. The country is a complex of tertiary eruptives, including rhyolite, dacite, andesite, and basalt. Of these the Wonder rhyolite is the oldest. It is a basic type of rhyolite, which, from its mineralogical and chemical composition, might well be called a quartz latite; but it has been commonly known as the Wonder rhyolite. The ore-bearing veins of the district occur in this 'rhyolite,' usually near small intrusive masses of a more acid rhyolite. They are composed chiefly of quartz and a white potash-feldspar. There are many of these veins in the district, most of which contain small deposits of silver-gold ore; but none, except the Nevada Wonder vein, has produced sufficient ore to pay for mining. The Nevada Wonder vein outcrops at the surface. It lies partly on the contact between the 'rhyolite' and an intrusive body of dacite, but toward the north the vein leaves the contact and lies entirely within the 'rhyolite.' The strike is N. 25° W., and the dip 75° E. The ore consists of quartz rudely banded with feldspar. Oxidation extends to the 1300-ft. level. The oxidized part of the vein forms the cleanest silver-gold ore, from a mining and milling point of view, that I have ever seen. The gangue is composed of quartz, feldspar with its usual decomposition products, and occasional small quantities of fluorite. It is stained yellowish brown with limonite, although some of the ore is white. The silver is in the form of argentite and halogen salts, and the gold is both native and combined with the argentite. Oxide of manganese occurs only in small dendritic forms, except in unimportant local concentrations. Copper and lead occur only in traces. No zinc was found above the 1300-ft. level, and there is practically no arsenic or antimony.

The silver haloids found were embolite, iodobromite, and iodyrite, which are respectively the bromo-chloride, iodo-bromo-chloride, and iodide of silver. No cerargyrite was seen. As at Tonopah, the percolating waters contained the alkaline salts of chlorine, bromine, and iodine.

which caused the selective precipitation of corresponding secondary silver minerals in separate horizons. There was this difference, however, that while at Tonopah the silver took the form of chloride, bromo-chloride, and iodide, at Wonder it took the form of bromo-chloride, iodo-bromo-chloride, and iodide, the order being downward as named. The best example of this was in what is known as the Extension ore-shoot where embolite was found to a depth of 950 ft. and iodobromite from that depth to the 1300-ft. level. Iodyrite was found in limited quantity and in collectible amount only in one locality on the 1000-ft. level, where, in a hanging-wall branch of the vein, there was an unusually rich deposit of silver sulphide which had been shattered and partly oxidized. Iodobromite occurred in films and crystallized coatings throughout this mass, among which were some pretty specimens. At the lower limits of this enrichment, a small pocket of loose iodyrite crystals was found lying immediately under rich fragments of ore. As at Tonopah, jarosite, the hydrous sulphate of iron, was prominent among the decomposition products associated with the iodyrite. It will be observed that, although this iodyrite was not found at the lower limit of the iodo-bromite zone, it was in a channel separated from the main body of the ore. In this position the rich ore had the effect of intensifying the precipitation of the chlorine and bromine and reducing their concentrations, until the solution was sufficiently weak in these elements to permit the precipitation of the iodide. In the main vein, however, the iodobromite zone extended to the lower limits of oxidation at the 1300-ft. level. While the iodide was uniformly precipitated separately from the chloride and bromide at Tonopah, it was, with the trifling exception noted, precipitated in combination with them at Wonder. The reason for this is apparently that the percolating solutions in the two places contained different concentrations of the chlorides, bromides, and iodides. Emmons says: "If, in a solution containing the three halogens, chlorides are vastly in excess, silver chloride will be precipitated first, even if bromides and iodides are present, for, in a mixed solution, the least soluble salts are not precipitated first, if a more soluble salt is present in sufficiently great concentration."

Evidently the concentration of chlorine was less in proportion to that of bromine and iodine at Wonder than it was at Tonopah. The minerals associated with these halides were the quartz and feldspar of the vein with their usual decomposition products, limonite in com-

¹William Harvey Emmons, "The Enrichment of Sulphide Ores," Bulletin 529 U. S. G. S., 1913.

*Abstract: 'Economic Geology', Oct.-Nov. 1917.

paratively small amount, manganese dioxide in small amount, and wulfenite. The last occurred in small amounts in the iodobromite zone, though there seems to be no obvious connection between the two. As previously mentioned, flaky jarosite occurred with the iodyrite, but not noticeably elsewhere. It is noteworthy that no pure bromide of silver was identified either at Tonopah or Wonder.

The source of the halogen salts of the alkalis appears to be in the salt lakes that formerly existed in this region. Alkali flats, and salt beds of commercial importance, lie within 25 miles of Wonder. As far as I have been able to ascertain, the accumulations of salt in the Great Basin have not been tested for iodine or bromine, but George Otis Smith has informed me that bromine was detected in the brines from Searles Lake, California. Doubtless, close analysis would show that they exist in practically all of these accumulations of salt.

Embolite, $\text{Ag}(\text{BrCl})$, occurs as grayish-green, waxy, translucent coatings and groupings of deformed crystals adhering to the ore. Where the mineral is abundant, it is sometimes found in the form of loose crystals, often of cubical form, lying in cracks and openings. It is often associated with wulfenite. It has a perceptible odor of bromine. It is sectile and has no cleavage. The symmetry is isometric.

Iodobromite, 2AgCl , 2AgBr , AgI (Dana), the iodobromo-chloride, occurs as light to dark olive-green, translucent, lustrous, crystalline coatings, and loose imperfect crystals. Crystal-surfaces have a brilliant lustre. The mineral has no cleavage and is sectile. It is associated with a small amount of wulfenite and an occasional loose crystal of iodyrite. The odor of bromine is apparent. The symmetry is isometric but perfect crystals are rare.

Iodyrite, AgI , the iodide, is found in pockets of loose sulphur-yellow crystals in cracks and cavities in the ore, and in occasional crystals associated with iodobromite. The symmetry is hexagonal hemimorphic. The mineral is sectile and has well-defined cleavage. It has a distinct odor slightly milder than that of iodobromite or embolite. The odor of these minerals, as a class, is one of their most distinctive characteristics, though I do not know that it has been mentioned before in print. It is best described as a drug-store or laboratory odor, reminding one strongly of the characteristic odors of those places, and is not as rank as the odor of chlorine or bromine gas. Of the specimens that I have at hand, embolite and iodobromite smell alike, though iodobromite is the stronger. The smell of iodyrite is milder and less penetrating than that of the other two. The odor of these minerals is sufficiently strong, so that on entering stopes where a deposit had been newly found, I have frequently been made aware of its presence through the sense of smell.

UNDER the recently enacted revision of the Texas mining law claims covering mineral deposits not occurring as lodes may consist of four sections, or about 2400 acres, on which the usual assessment work must be done, and a royalty must be paid to the State.

Tariff Commission Asks for Data

The Tariff Commission is making an inquiry into the significant developments that have taken place in the chemical industries since the passage of the tariff act of 1913. Changes which seem likely to alter permanently the conditions of international competition or the course or volume of foreign trade are of special interest. All persons having direct knowledge of pertinent facts in regard to any particular industry or product are invited to submit a statement to the Tariff Commission. Among the matters on which the commission desires information are:

1. The manufacture within the United States of articles formerly unavailable or obtained exclusively by importation; for example, phosgene.

2. In the case of industries previously established in the United States, the erection of new plants or increase in capacity of existing plants; for example, the increase in capacity of existing plants for making caustic soda and chlorine.

3. The future of industries newly created, or in which productive capacity has been greatly increased to meet a direct war-demand. How can these plants be utilized when the war-demand disappears?

4. Any general or significant differences in the prevailing methods of manufacture here and abroad.

5. Differences in the organization of the industry here and abroad.

6. The development or invention in the United States or abroad of new or improved processes which are likely to influence the conditions of international competition; for example, the hydrogenation of fatty oils or the flotation process for concentrating ores.

7. Significant changes in the conditions of international competition caused by the recent law making patents owned by citizens of enemy countries available to American manufacturers.

8. Industries which have been seriously hampered in their normal operation or development by difficulty in securing materials or supplies formerly imported; for example, the lack of potash for fertilizer or glass. If these difficulties have been met by the introduction of substitutes, is it expected that there will be a return to the old materials and methods when foreign supplies again become available, or will the changes be permanent?

9. Developments or changes in other industries which have created a new or greatly increased demand for chemical products; for example, the manufacture of new varieties of glass.

10. The discovery of new uses of materials, creating a new demand or furnishing a market for materials formerly wasted; for example, the use of aniline as an accelerator in the vulcanization of rubber.

11. Any governmental hindrances in the United States or abroad, either in manufacture or commerce; such as the export duty on nitrate from Chile.

The commission will publish only general statements or summaries, which will not reveal the operation or plans of individual companies.

REVIEW OF MINING

NEW YORK

WEATHER CONDITIONS BETTER.—STOCKS AND BONDS.—COAL, GAS,
AND ICE.—POSTAGE RATES.

A return to more favorable weather conditions gives promise of a resumption of normal activity in the near future. The effects of the recent legalized disorganization in industry are only now being realized in some phases of business. Reduced income means reduced buying and more cautious expenditure. Delivery delays have led to repudiation of contracts, and other effects are observable. Clearing House figures show a decrease of about 24% in the amount of payments through the banks in New York City, as compared with the corresponding week last year. This may be taken as an estimate of the dislocation caused by the recent state of chaos.

The stock market shows a continuous diminution in trading, with no marked change in average quotations. Bonds may be divided into two classes, namely: Liberty bonds, and the rest. The latter have appreciated in value for the most part during the week. Liberty bonds, on the other hand, have again reached low records, the 4% issue at one time touching 95.10, thus showing a loss from par of \$49 per \$1000. A bill has been proposed which would set aside a sum not exceeding \$60,000,000 for the purpose of stabilizing the price of these bonds. The fund would be used to purchase for cancellation any bonds that might be offered at below-par rates. In has been stated that the method is in successful operation in France and England; and that the British Treasury only spent \$132,000,000 from its stabilizing fund last year to prevent slumping of war bonds. New York financial opinion claims that the \$60,000,000 fund suggested would be altogether too small to have any appreciable effect on the downward trend of the market.

Thanks to a more moderate temperature the coal situation is improving. Eastern railroads show less congestion and haulage is rapidly assuming normal operation. The Monday closing order has been rescinded for several Southern States, but still remains in full force in New York. Yesterday the offices in many buildings without artificial heat maintained a comfortable temperature, but the order strictly enjoins that not even one elevator shall run, so that all business was successfully killed. In some quarters it is considered that the coal shortage is in part due to the fact that heavy shipments of coal have been made to our Allies in Europe. This is far from being the case. Great Britain exported \$256,700,000 worth of coal and coke during 1917; and was able, during the past week, to relieve the local fuel famine to a slight extent by the transfer of a cargo of coal held here and consigned for bunkering British ships. The reduction in quality of present coal consignments has been explained by the fact that, as long as prices remain fixed, coal miners will work only the inferior grades and the most accessible deposits.

The unprecedented demand for gas during the recent coal shortage was fully met by the various companies whose facilities to meet an abnormal situation calls for the highest commendation. During January the city consumed 6,650,315,700 cu. ft. Some companies were able to meet a 60% increased demand.

The possibility of an ice famine next summer having been

duly realized, natural and artificial-ice manufacturers conferred on the possibilities that might arise out of such a situation. An amicable agreement was reached, and the harvester companies decided to cut an extra 1,000,000 tons, forgetful of the circumstance that a short time ago it was decided to insist that there was no available labor, no storage facilities, and the ice was too thick anyway. Their patriotic action in endeavoring to minimize future distress has been eulogized, but the decision was so coincident with the news that an Ice Controller was to be appointed that their action was perhaps of not so disinterested a nature as was first thought. The new Ice Controller will be authorized to cut up to 2,000,000 tons for subsequent sale, and an adequate appropriation will be made for this purpose. The action of the authorities in this matter is a subject for favorable comment.

New York City possesses 14 postal districts and the same number of general post-offices. Letter postage from Manhattan to Brooklyn is the same as from Manhattan to San Francisco, and the same three-cent rate applies to all interborough postage. The two-cent rate applies only to 'drop letters,' that is, letters mailed in the same district in which they are to be delivered. A bill for the uniform two-cent rate throughout the city is under consideration and would command general approval. The Chamber of Commerce, in support of the scheme, shows that a two-cent rate prevails in all the Boston post-office districts. The penalizing of New York in this respect would seem entirely unreasonable and partial.

CRIPPLE CREEK, COLORADO

UNITED GOLD MINES.—EL PASO LESSEES.—MODOC CONSOLIDATED.
—CLYDE AND ROSE NICOL MINES.

Producing mines of the United Gold Mines Co.—Trail, Bull Hill, W. P. H., Ironclad Hill, Bonanza, Battle Mountain, Wild Horse, also Damon dump on Ironclad hill—yielded 2100 tons of \$20 ore during January. The Trail, with four sets of lessees, yielded 1710 tons.

Cripple Creek Deep Leasing Co., operating the Jerry Johnson mine, sent out 500 tons of 1-oz. ore in January, mined from above the 850-ft. level.

Lessees—12 sets of the El Paso Consolidated Gold Mining Co. forwarded 500 tons of \$18 ore to the Golden Cycle mill at Colorado Springs in January. The company is still inactive.

Modoc Consolidated Mines Co. is mining good ore on No. 15 and 16 levels of the Modoc incline. 80 tons shipped last week returning \$30 and \$35 per ton.

The Millasier Mining Corporation is cutting a station at a depth of 1450 ft. of the Clyde, on the north-east slope of Battle mountain, and the superintendent, Charles Fish, has started to cross-cut for the Clyde vein this week.

Ore has been cut on the 800-ft. level of the Rose Nicol shaft on the north-west slope of Battle mountain, and shipments will soon be made. The mine owned by the Rose Nicol Gold Mining Co., is under 6 years' lease to the Camp Bird Mining, Leasing & Power Company.

Dissolution notices of the Rubie Mining & Leasing Co. and Peggy Leasing Co. have been filed for record with the clerk and recorder of Teller county.

The Vindicator Consolidated meeting was held February 14.

PLATTEVILLE, WISCONSIN

FACTORS HINDERING ZINC MINING.—ZINC, LEAD, AND PYRITE
PRICES.—NEW PLANTS.—POWER RATES.

Snowstorms in January made conditions bad for February, and the first half of this month found producers contending against wretched roads, scarcity of cars, low temperatures (at one time 30° below zero), and lowering prices for zinc ore. These factors resulted in the first 15 days showing a maximum output of zinc ore of about 50% of normal. Lack of fuel compelled power companies to curtail output, working schedules being sadly disorganized for days at a time. Train schedules were totally abandoned for days, and in the northern part of the field even mail service was discontinued for the first five days. In the Pecatonica and LaFevre River valleys, where are many of the best zinc mines of this region, managers took precautions against thaws and the possibility of flooded workings. Mines removed some distance from railroad, and compelled to transport ore by team or auto-truck, have been hindered from making deliveries, but bad as conditions are, it is freely admitted that a long period of idleness is sure to be forced on operators when the spring break-up comes a month hence. The entire field is covered with a mantle of ice and snow in places house-high, and a long season of fair weather will be required to first remove the snow banks, and after that the muddy roads.

Prices for zinc ore were discouraging. The base on first-grade ores on February 1, namely, \$62 per ton, receded to \$60, with the range down to \$50 on second and medium-grade ores. Less latitude was allowed on the lower grades, the line being drawn on assays not lower than 54% zinc content. On ores under 40%, the bulk of which finds its way to separating plants in the field, discrimination was decidedly sharp, and offerings became so unsatisfactory that reserves piled up in all the districts where low-grade producers predominate.

Lead-ore producers had more reason to be joyful, as offerings held firm the first 15 days of February on a base of \$85 per ton, 80% metal content. Sellers refused to sell until offers returned to \$100 per ton, and only 74 tons cleared in the first two weeks. The curtailed output of zinc ore is attended with a smaller yield of lead ore, so that no great appreciation in stocks is shown; but it is now estimated that there is 3000 tons of choice lead ore held in bins in the Wisconsin field.

Sale of iron pyrite was stimulated somewhat during the period by reports from Washington, D. C., of the immediate commandeering of sulphuric-acid supplies by the Government. Producers at liberty to sell on open-market quotations secured better figures than usually prevail, but the bulk of sales made sold off under contract arrangements much to the openly confessed displeasure of refiners so bound. The reserve in the field is conservatively estimated at 5000 tons.

A new 500-ton mining and milling plant was completed for the Wisconsin Zinc Co. at the Copeland mine in the Shullsburg district. The plant proved satisfactory from the start.

Another 600-ton power, mining, and milling plant completed for the Vinegar Hill Zinc Co. on the Jefferson mine, in the Hazel Green district, was placed on a double-shift schedule. It is claimed the new producer is capable of yielding a car of zinc concentrate daily.

In the Galena district more interest is being shown than for many years, following numerous strikes of both zinc ore and lead ore near the city limits.

The Blewett Mining Co. was organized under the laws of Illinois, with a capitalization of \$100,000. The Burr Mining Co. of Benton, Wisconsin, a successful producing corporation for the past three years, is financing the new undertaking, and plans have been drawn for a new 500-ton concentrator, the work to be started with fair weather. Drilling operations followed over a period of several months resulted in the blocking out of a big zinc deposit in places 30 ft. thick.

The burning of the White Rose mine plant, one of the Gus E. Brown producers, entailed a loss of \$15,000. This followed a rich discovery of lead ore, nullifying for the time its value. Miners are engaged in hoisting the ore and hand cleaning is resorted to until the plant can be re-built.

An announcement by the Inter-State Light & Power Co. of Galena of an increase in power rates was promptly met by a protest filed by operators with the State Industrial Commission. Legal talent was promptly employed by both principals, and a hearing was held before the Commission lasting more than a week. The matter has been taken under advisement, and until a decision has been rendered the rates in effect prior to the announcement will continue to prevail.

The Lawrence Mines Co. of Dubuque, Iowa, now in control of the Indian Mound mine at Benton, has acquired valuable mineral leases in the New Diggings district, and a local office has been established at the latter place. The new lands will be thoroughly explored with drills, and mine development is proposed on a large scale. The Indian Mound mine, for years an indifferent producer, under the new management has developed into one of the best single producers in this district, and it is claimed will be fully opened in the coming spring. The Lawrence mine in the Hazel Green district, operated for several years, has been permanently abandoned.

The McMillan Zinc Co., fully equipped, has, after two years work, shut-down temporarily. High cost of labor and supplies and an exceptionally heavy flow of water compelled the stoppage. More capital is required to bring the McMillan to a producing basis. It is claimed by the promoters that a large body of zinc ore has been proved, and only cash is necessary for profitable results.

SUTTER CREEK, CALIFORNIA

CENTRAL EUREKA.—KEYSTONE REPORT.—ONEIDA.

Shaft-sinking is to be resumed at the Central Eureka mine during the present week and active preparations for the work are now in progress. It is believed possible to keep 30 stamps dropping on ore from the 2500 and 2700-ft. levels until the shaft is sunk another 500 ft. The present depth is 3450 ft., and there are excellent indications that veins apexing on the present lowest level will yield handsomely at increased depth. The equipment recently has been inspected and brought to comply with boiler-safety rules; arrangements have been made to increase the use of compressed air as an auxiliary for steam. Fred Jost is superintendent. Semi-annual report of the Keystone company shows that the 40-stamp mill lost only 24 days in the six months ended December 31. During that period 43,151 tons of ore was crushed, yielding bullion to the value of \$7781 and concentrate worth \$107,374. After deducting freight and smelter charges of \$24,548, there is an income from ore sold of \$90,606, or about \$2.10 per ton. Despite the low grade of the ore milled, a profit of \$5634 is recorded for the six months. The three lower levels, 1200, 1400, and 1800-ft., each produced from 11,000 to 12,000 tons of ore, while the 900-ft. level is credited with a production of 2896 tons and the 1000-ft. level with 5636. A shaft station is now being cut at the 2100-ft. level. The vein formation cut in sinking the shaft gives promise of this level producing better ore than levels above, and the intention is to cross-cut east and west at this point. The work to the east is for the purpose of cutting the vein worked in the level above and that to the west having as its object the prospecting of the Mother Lode slates, so strongly in evidence on the 2600-ft. level. This work will prove the ground about midway between the bottom of the old workings and the ground exploited from the 2600-ft. or lowest level of the mine. Several months will doubtless be required under present conditions to thoroughly prospect this ground. A raise is being driven from the 900-ft. level and, at the present height of 95 ft., shows a large body

of low-grade quartz. Stopping is in active progress on the 1000-ft. level, 500 ft. north of the shaft and from two stopes on the 1200-ft. level. While no driving has been done on the 1400-ft. level for several months, a large tonnage of milling ore is in course of extraction from stopes above the foot-wall drift, north of the shaft. Driving is in progress both north and south on the 1800-ft. level; the work to the south having opened a large tonnage of ore and prospects being excellent in the work to the north. Carlton R. Downs is superintendent of this property, which has been in almost constant operation since its discovery in 1851. Miners are pleased with the rainfall, as the power company had notified the mines in Amador county that lack of snow on the summit would render it necessary to cut off the supply of electricity and water within the next few days. The present storm here, which means increased snow in the mountains, will doubtless prevent a serious shut-down of the mines.

DEADWOOD, SOUTH DAKOTA

MINERAL PRODUCTION OF BLACK HILLS IN 1917.—NEW PLANTS
ERECTED AND BEING BUILT.

Gold bullion production of South Dakota in 1917 was valued at \$7,518,333, extracted from 1,860,904 tons of ore, according to the annual report of the State Mine Inspector. Producers were as under:

Producers	Tons	Value
Homestake	1,670,476	\$6,636,622
Trojan	113,121	471,268
Golden Reward	33,328	198,040
Mogul and Ofer	35,980	187,317
Homelode	450	1,850
Columbia	64	3,484
Bismarck	2,325	3,720
Elk Mountain	3,120	9,216
Monarch	28	922
Placer		1,000
Miscellaneous	10	4,893

Gold output for 1917 is only slightly below that for 1916.

There was also produced 267 tons of tungsten concentrate valued at \$320,009. Most of this was taken from the Homestake, although Wasp No. 2 made one shipment.

Lead-silver mines were more active than for some years, and 267 tons of ore was shipped, valued at \$6695. Most of this was from the Galena district, only 20 tons coming from the southern hills.

Tin operations resulted in an output of 22 tons of concentrate worth \$3200. This was recovered at Hill City, while small amounts of stream tin were obtained in the Tinton district.

Of mica 328 tons was shipped from Pringle and Berne, valued at \$9259.

Lithia ore, 1281 tons, valued at \$25,620, was shipped from the Rheinbold and Standard Essence properties at Keystone.

Eighty tons of copper ore worth \$1888 was shipped from the Black Hills, Blue Lead, and Southern Queen properties in the southern hills.

In addition to the minerals mentioned there were produced pyrite, manganese, coal, kaolinite, gypsum, limestone, and structural materials, and the value of all, including those mentioned above, is placed at \$8,201,448.

Employees numbered 2757, compared with 3069 in the previous year. There was a noticeable decrease in underground workers. Seven fatal accidents resulted from mining operations.

New plants were completed during the year by the following companies: Homestake, power-plant; Homelode, amalgamation-concentration mill; U. S. Gypsum Co., 100-ton plaster mill; Dakota Plaster Co., 180-ton plaster mill; Refinite com-

pany, plant for kaolinite treatment; and Custer Peake, 10-stamp mill and concentrator completed. Under construction are Spokane Lead & Silver, 100-ton concentrator; and Deadwood Lead & Silver, 10-stamp mill and concentrator.

LEADVILLE, COLORADO

CAR SHORTAGE.—PYRITE DEPOSITS.—SILVER DISCOVERY.—STUDY OF MATCHLESS GROUND.—ROY AND GREENBACK DEVELOPMENT.—MANGANESE.

Ore production of this district is being seriously handicapped by the continued shortage of railroad cars and the inability of the Colorado & Southern to handle its end of the business. Mines that secure service from this road are without empty cars half of the time. One company that normally loads three 60-ton cars per day has had only five cars in two weeks. The other roads, although often without the required number of cars to supply their demands, are giving fairly good service.

The Leadville Unit of the United States Smelting, Refining & Exploration Co., operating the Harvard, Tip Top, and Jamie Lee shafts on Fryer hill, has just made the most important discovery in its development here. An immense body of iron pyrite has been found between the Denver City and Jamie Lee shafts, and from 100 to 150 tons daily is now being shipped. The pyrite carries silver.

A new ore-shoot, which promises to be the largest yet found in the mine, was discovered on February 10 in the Bartlett on Sugar Loaf. The ore shows considerable ruby silver. The shoot occurs in the same big fissure that was cut late in 1916, when the first important discovery was made. Last year \$30,000 in silver ore was extracted from the vein, but the ore-shoot pinched out, and for several weeks the lessees have been driving through a barren section. Operations at the Bartlett are done through a winze that is down 50 ft. below the main tunnel-level, which is 300 ft. from surface. Both the first ore-shoot and the body just opened extend under the present workings from the winze, and the lessees propose to sink another 50 ft. The winze is equipped with a 250-gal. electric pump and a 37-hp. hoist.

Efforts of Edward Huter, manager for the Matchless Mining & Leasing Co., to find the second contact in Fryer hill, have so far been unsuccessful. Matchless No. 5 shaft has been sunk through the parting quartzite, which was 25 ft. thick, and has been continued in the underlying porphyry an additional depth of 68 ft., giving the shaft a total depth of 350 ft. At this point the bottom remained in porphyry, with no apparent indications of any change in the formation being at hand. Sinking has been discontinued, and further prospecting below will be done by diamond-drill. It is believed that the white lime exists under the porphyry, forming the second or sulphide ore-zone that for years has been an unknown and alluring factor in Fryer Hill development. Work at the Matchless is important in that it will demonstrate beyond doubt whether or not a second contact really exists. Sinking at the Hayden shaft on Yankee hill, which was undertaken last year, failed to penetrate the lower porphyry, but an underlying lime was encountered at the Jamie Lee shaft of the Leadville Unit. No mineralization was found, however.

Heirs of the Thomas F. Walsh estate are planning to extensively develop a large tract of ground known as the Roy group on Canterbury hill. This area was one of the first possessions of the late Mr. Walsh, but owing to his numerous other holdings he was able to complete only a small amount of development in it. The property is in line of the proposed Prospect Mountain tunnel, and is thought by local people to be on the extension of several large veins that traverse the Fryer Hill territory across the gulch. Work will probably be started early in spring, as the agents for the estate have been here inspecting it and are securing prices on machinery.

The owner of the Greenback shaft, Patrick Mulrooney, is again draining his property to the bottom level, a depth of 1350 ft. During the past few months development in the Greenback has been confined to the area extending above the 1100-ft. level, and the water was allowed to rise to that point. Orebodies on the 900, 1000, and 1100-ft. levels have been opened, and a regular tonnage of good ore is being extracted. Larger and richer deposits are known to exist below and the work of reaching them is now in progress. Electric and steam-pumping equipment has been installed.

G. P. Goodier of Denver has purchased the Jason lease on Poverty Flats from Mrs. Florence Doty, also of Denver, for \$10,000. For several years the Jason has been a continuous producer of iron oxide, carrying silver and manganiferous iron; and at one time was credited with an output of 100 tons daily. Early in 1917, when the demand for domestic manganese ores caused Government investigation of all the known manganese sources of the country, the Jason was one of the first properties in the Leadville district to be listed. At that time it was shipping steadily to the Colorado Fuel & Iron Works at Pueblo, and a large tonnage was blocked out in the mine. The material was rated as high-grade manganese, averaging 30% manganese and less than 10% silica, and it was not long before Eastern buyers were bidding for the ore. During the past year several lots were shipped East and brought good returns; but the recent traffic complications caused the Jason operators to again ship their entire output to Pueblo. At the present time, two distinct deposits of manganese are being developed in the Jason. Both of these occur on the 250-ft. level, and have been opened for several months. Measurements made just prior to the sale showed one body to be 22 ft. long and 17 ft. wide, the other 16 ft. long and 11 ft. wide. The top of these deposits has not been reached. Under existing conditions, which place a premium on manganese ores, the Jason product is unusually fine. The ore carries as high as 34% manganese and has a silica content of from 5 to 6%. Mr. Goodier, the new owner, is preparing the property for a greatly increased production, and may contract with Eastern buyers who offer high prices for the ore. Beginning March 1, the property will ship 50 tons daily.

ELY, NEVADA

FUEL.—CONSOLIDATED COPPERMINES.—NEVADA UNITED.—TUNGSTON.—WILLOW CREEK.—MANGANESE.

Coal conditions in the Ely district are better than for months. The Nevada Northern railroad and the Nevada Con. Copper Co. have 40 to 50 days' supply. Both have discontinued running their own cars to Utah coal mines. Coal and wood yards here have good stocks. The exceptionally warm winter has been a great help to the fuel situation. The Nevada Consolidated is keeping up its regular production.

The Coppermines company continues its development policy. It expects to be able to re-start its 1000-ton experimental mill on March 1. This has been closed for repairs and mine development since January 1. The power problem is serious. The nearest hydro-electric power is obtained near Round Mountain, Nye county. Recent estimates of delivering power here is \$600,000, and the Federal authorities object at this time. The Nevada Consolidated could furnish it by increasing its steam-generating plant at a minimum outlay, but is prohibited under State laws, as the company is classified, when selling power, under the General Utilities Act.

The Nevada United company (old Ward mine) is shipping 30 tons daily of lead-silver ore with an iron base, as fluxing ore to Utah smelters. Development continues satisfactory.

O. E. Roodhouse, formerly superintendent for the U. S. Tungsten Co., 12 miles south of Osceola, is dismantling machinery in the mill and shipping it out.

William Stewart is employing a few men at the Minerva scheelite property, a few miles south of the U. S. company's mine.

A. R. Shepherd, manager of the Tungstania Mines Co., is milling a little ore.

The Red Hills lead-silver mine, in the north-eastern part of White Pine county, is being developed under bond and lease.

The Willow Creek gold camp, 100 miles south-west of Ely, is again in the limelight. Recent development has found the original surface discovery shoot of high-grade ore at 100 ft. depth. While there is several feet of good milling ore, there is a shoot about two inches thick, said to be fully one-fourth free gold. It is estimated that there is from \$75,000 to \$200,000 of gold in this shoot.

The Liberty Gold company, a Salt Lake City, concern, operating near the first discovery of the district, on one made last year, has a good showing.

Manganese mining is becoming active in the Ely district. Holmquist and Bowen, 7 miles south-east of Ely, are shipping 20 to 25 tons daily. Development at 60 ft. has opened a large deposit of 60% ore, according to the owners, who refused a fancy cash price for the mine. Italians on adjoining property are shipping 10 tons daily. A. B. Witcher has just shipped his first carload from a discovery within 1/2 mile of the court-house. Others are leasing claims and mining manganese.

TINTIC, UTAH

GEMINI AND GODIVA COMPANIES.—DRAGON FLUX ORE.—ZUMA DEVELOPMENTS.

Shareholders of the Gemini Mining and Godiva Mining companies met on February 5 in annual session and elected directors for the ensuing year. The two companies are under the same management, and the officials are practically the same. The Gemini re-elected as president, E. W. Packard; vice-president and manager, J. C. McCrystal; treasurer, E. O. Howard; secretary, J. E. Berkley, who, with W. V. Cott, are directors. Preliminary reports were submitted. That on the Gemini covered 14 months, up to December 31, 1917. Dividends totaled \$130,000, of which \$100,000 was paid in 1917. Gemini shipped 489 carloads of ore, or about 24,000 tons, in 1917. The Godiva shipped in January 1918 one carload, or 50 tons; and the Gemini 32 cars, or 1500 tons. In 1917 the Godiva shipped about 1200 tons. Smelter embargo and shortage of cars kept the McCrystal mines from recording a much larger tonnage of ore during 1917.

During December the Dragon Consolidated shipped 8000 tons of ore, also a similar amount in January, and probably the same will leave the property during February. While much of this output is an iron product of rather low grade which is in demand at this time, the Dragon is producing considerable ore—silver, lead, and copper. It is understood that the smelter desires a large tonnage of fluxing ore from this mine, and the present output could be increased if more care were available. Earnings of the Dragon have been entirely satisfactory for many months. One of the most important explorations under way is sinking a winze from the 1000-ft. level. It is down 600 ft., and 150 or 200 ft. additional sinking will be done before cross-cutting is started. This winze will prospect virgin ground.

Reports from the Zuma are encouraging. The winze started from the 500-ft. level to follow a shoot is 80 ft. below the level with sinking still in progress. The winze has been in ore all the time, although the shoot has varied in size. A drift if being driven along the vein on the 500-ft. level, where there is another good shoot. The management is confident of being able to bring the property into the productive stage during 1918.

THE MINING SUMMARY

ALASKA

Fairbanks.—Early in February fire destroyed the round-house and machine-shop of the Government railroad at Nenana. Besides the loss of \$75,000 to \$100,000 of property, progress will be considerably hindered.

Juneau.—Gold yield of Alaska Gastineau in January was the lowest on record, being 179,300 tons of ore assaying 90.3c. per ton. The recovery was 77.85%.

Kennecott.—Copper production of the Kennecott company in January is given as 12,170,000 lb., of which about half should be credited to Braden in Chile.

Valdez.—An aerial tram, 28,360 ft. long, has been erected by the Riblet Tramway Co. of Spokane for the Granby Consolidated company at its Midas mine. The tram is the largest in Alaska. It is divided into six sections, with a total of 77 towers. The largest span is 3050 ft. The cable for loaded skips is 1½ in. diameter, and for empties ¾ in. Eighty buckets of 1000 lb. capacity each are in use. The cost complete was \$3.66 per foot, and cost of operation 0.328c. per ton carried.

ARIZONA

COCHISE COUNTY

Bisbee.—Calumet & Arizona produced 4,748,000 lb. of copper in January, compared with 4,054,000 lb. a year ago, and 5,816,000 lb. in December.

Shattuck-Arizona in January produced \$49,440 lb. copper, 84,000 lb. lead, 9599 oz. silver, and 106 oz. gold; against 1,415,303 lb., 425,638 lb., 19,105 oz., and 211 oz., respectively, a year ago; but an improvement on the December output.

Douglas.—A new record was made in January at the Copper Queen smelter, production being 21,700,000 lb. of copper, against a little over 2,000,000 lb. in December. Besides the ores mined from the Copper Queen at Bisbee, this yield includes ore sent from other mines owned by the Phelps-Dodge interests, such as the Burro Mountain Copper Co. at Tyrone, New Mexico, and Moctezuma Copper Co. at Nacozari, Sonora. Considerable custom ore is also treated, one of the principal shippers being the United Verde Extension in the Jerome district.

Globe.—Copper production of the Old Dominion company in January was 3,400,000 lb., against 3,000,000 lb. a year ago, and 3,368,000 lb. in December.

The Employees Committee of the Old Dominion company recently petitioned the management for a company store, stating that the general prices of the Globe merchants are too high as compared with those in other communities. There were 832 signatures to the petition. When asked about the matter, W. G. McBride, general manager for the company, said: "I have taken the matter under consideration and intend to make a thorough investigation of the question, and to secure all the data possible before making any recommendations. The company does not wish to enter into competition with the merchants of Globe, but it is very anxious to have its employees secure the essentials of life at reasonable rates. I will not recommend my company to go into the mercantile business here unless the results of my investigation go to show that local merchants are charging unreasonable prices. If, however, I find the men are being unfairly treated and that

the evil cannot be remedied in any other way, I will certainly use my influence to have our company start a store or commissary. However, I feel that there are quite enough stores in Globe now to supply the needs of the community and I hope that the business men will co-operate with the company and its employees to the end that the cost of living may be kept as low as possible."

Miami.—Copper production of Inspiration Consolidated in January was 5,000,000 lb., against 5,600,000 lb. in December, and 11,600,000 lb. a year ago.

MARICOPA COUNTY

Wickenburg.—The Rich Hill Gold Mining Co. has been incorporated to work the old Johnson gold mine on Rich hill. E. C. Lane is in charge.

PIMA COUNTY

Ajo.—Copper production of New Cornelia in January was 4,136,000 lb., against 3,850,000 lb. in December, and 4,660,000 lb. in November.

PINAL COUNTY

Superior.—Fortuna Consolidated Mining Co., operating in the Magma district, reports cutting ore assaying 125 oz. silver and 7% copper. An adit is being driven on a small north and south vein to intersect a large east and west vein system, supposed to be an extension of the vein which the Magma and Silver King mines are operating. The east and west vein has not yet been cut. The adit is in 900 ft. and shipping ore a foot wide has been found. It is expected that the adit will open a large orebody at the intersection of the two veins, as the Magma found its orebody at a somewhat similar point.

YUMA COUNTY

Swansea.—The Argus copper mine, adjoining the Planet, has been taken over by Ernest C. Lane, formerly in charge of the Swansea mine, and active development will be started at once. A large hoist, compressor, pumping-plant, and other necessary machinery to sink the shaft to a depth of 500 ft. is now on the ground, and will be installed at once.

ARKANSAS

SEBASTIAN COUNTY

Fort Smith.—The Fort Smith Spelter Co. has resumed smelting, after being shut-down since November 6. Four blocks, with a total of 2560 retorts, are now at work; also about 200 men.

CALIFORNIA

AMADOR COUNTY

Sutter Creek.—At the Old Eureka mine the shaft is down 2165 ft., with sinking proceeding at 17 to 20 ft. per week. The shaft will be sunk 1000 ft. deeper. Some good ore has been opened at 1600 to 2100 feet.

As money could not be secured for development, the South Eureka company may suspend work at its South Eureka and Onelda mines.

INYO COUNTY

Bishop.—Three tungsten mills are at work in this district, another is ready for operation, while construction of a 150-

ton plant at the Beauregarde is to be started soon. The monthly payroll of the tungsten properties is \$30,000.

KERN COUNTY

Randsburg.—On February 22, 23, and 24 a convention is to be held here by the District Miners and Claim-Owners. Its purpose is to form an organization devoted to the mining industry of Kern, Inyo, and San Bernardino counties, to secure recognition by kindred organizations, also co-operation among large and small mine operators throughout the district, and keep them advised of the work of the American Mining Congress, to watch National and State legislation affecting mining interests, etc. R. E. Rose is secretary.

The Yellow Aster company is busy developing its recently-acquired Black Hawk gold claims. A 17-in. shoot is being opened.

NEVADA COUNTY

Grass Valley.—A new compressor and pumps were started at the Delhi last week, and unwatering is under way. A considerable amount of surface improvement has been done. A. A. Codd is manager of this property, which is near Columbia Hill.

SIERRA COUNTY

Alleghany.—Mining in this county is reported to be quiet this winter, largely due to high prices of supplies and wages. Owing to litigation, the Sixteen-to-One and Twenty-One mines are practically closed. Small crews are employed at the El Dorado, Plumbago, and Tightner mines.

Downieville.—The Mexican company is employing more men than any other in this district. Work continues steady at the Bessler, Kirkpatrick, Oro, and Rock Creek mines.

Forest.—A fair number is employed at Bald Mountain, North Fork, and Mugwump. At the last-named a gravel mill is working satisfactorily.

Sierra City.—Forty men are working at the Monarch mine, also a few at the Sierra Buttes and Young America.

COLORADO

Denver.—The 172-page report of the Smelter and Ore Sales Investigation Committee of this State is now being distributed, and those interested are advised to secure a copy, as only 1000 are available. Miners of base-metal ores should be especially concerned with this report. The Committee's work was to investigate all matters connected with the purchase and sale and marketing of metalliferous ores in Colorado. Some interesting charts and schedules are given.

LAKE COUNTY

Leadville.—In new ground the Dold Mining Co. has opened a large deposit of manganese ore. Since January 1 a contract called for 50 tons daily of this ore.

At Climax the Climax Molybdenum Co., a subsidiary of the American Metal Co., has finished its 250-ton mill, also completed arrangements for housing its 185 employees. About 5000 ft. of work has been done in ore, and monthly progress is 1000 ft. According to the manager, J. M. White, ore-reserves are considerable.

OURAY COUNTY

Ouray.—At the Genesee-Vanderbilt and Yankee Girl mines, on Red mountain, the Red Mountain Mines Co. is employing from 50 to 60 men. Snow has suspended shipments from the Genesee. Recent developments are reported as good.

During January the Camp Bird company advanced its adit nearly 600 ft.—a record. At this rate it is expected that the objective point will be reached by May.

TELLER COUNTY

Cripple Creek.—The shoot opened on No. 10 level of the Cresson is officially reported as the most important for some time. Reserves in the mine are estimated to contain \$3,327,513 net profit. During December the profit was \$61,291. On January 23, cash amounted to \$1,133,117, plus 30 cars of ore worth \$20,000 net.

IDAHO

BLAINE COUNTY

Hailey.—Seven feet of ore, assaying 5.8% zinc, 9.3% lead, and 4.8 oz. silver, has been opened at a depth of 280 ft. in the Black Barb mine, 12 miles west of this place. J. B. Sawyer is manager.

BONNER COUNTY

Sagle.—In No. 3 adit of the Armstead Mines company the vein is 10 ft. wide, of good grade. This is twice the width of that on No. 2 level, 1000 ft. above on the dip. On February 1 No. 3 adit was in 3543 ft., 451 ft. being driven in January. It is proposed to erect a mill in the spring. H. H. Armstead is president.

CLEARWATER COUNTY

Pierce.—Dredging operations by the Pierce company have been stopped here, and the boat is being re-built five miles upstream.

IDAHO COUNTY

Orogrande.—At the Orogrande Mining Co.'s property a 300-ton mill has been erected to treat from \$2.30 to \$3.60 gold ore. A profit of \$1 per ton is expected, and a recovery of 90%. William Hogan is now in charge.

SHOSHONE COUNTY

Burke.—On No. 5 level of the Hercules, at a depth of 2000 ft., an orebody from 35 to 40 ft. wide has been opened for 480 ft. The lead-silver ore is rich enough for smelting direct. The shoot pitches east. This development is of great importance to this large producer.

The Imperial Mining Co. has spent \$67,097 on development, and has driven over a mile of adit and cross-cut. In the upper workings 48% lead-carbonate ore was opened, and ore was exposed for 400 ft. A winze sunk 55 ft. below the high-grade shoot opened from 18 to 60 in. of 3½ to 5% ore. In the lower workings from the main adit no ore has been found.

Mullan.—According to J. B. Short of the Butte & Coeur d'Alene Mining Co., there is considerable activity in this district, including his own company, Carbonate Hill, Snowstorm, West Hunter, National, Copper King, and Reindeer Queen. The National is now making from \$12,000 to \$15,000 profit monthly.

Sunset.—On March 22 the Sunshine Mining Co. will decide whether it will join the consolidation of properties on the north slope of the mountain in the Beaver district. It is proposed to increase the capital from \$1,500,000 to \$2,700,000, and acquire contiguous ground, especially the Toughnut, Tuscumba, and Idora properties. The Idora Mining Co. has voted to join the consolidation.

MICHIGAN

HOUGHTON COUNTY

Houghton.—On March 20, Calumet & Hecla will distribute \$10 per share, the same as paid for the previous quarter.

Copper Range has declared a quarterly dividend of \$1.50 per share.

Allouez is producing 1900 tons of ore daily. The five electric locomotives are working satisfactorily.

White Pine Extension employs 50 men. Work is confined to No. 2 and 4 levels.

Tributers in the Winona averaged 15 lb. of copper per ton in December, against 17 lb. in November.

Mechanical tramming is in satisfactory operation on two levels of the Hancock.

MISSOURI

JASPER COUNTY

Joplin.—Production of the Komspletter region during the week ended February 9 was 6210 tons of blende, 245 tons of calamine, and 1473 tons of lead, averaging \$55, \$33, and \$84 per ton, respectively. The total value was \$476,922, making

\$2,782,082 for six weeks. The Oklahoma field contributed 3738 tons of blende, and 1146 tons of lead. The car shortage was partly relieved, and prices were practically unchanged.

The first drill put down by the Ten Commandments Mining Co., of Asbury, near Joplin, passed through ore from a depth of 212 to 276 ft., estimated to average not under 15% zinc. From 90 to 110 ft. depth the ore assayed from 3 to 5%. A mill is contemplated.

The Ferch Mining Co., operating a lease of the Continental Zinc Co. on West Seventh street, Joplin, has opened good ore to a depth of 224 ft., and is considered to have one of the most promising mines in the district.

MONTANA

FERGUS COUNTY

Kendall.—On February 15 the Barnes-King Development Co. distributed 10c. per share, equal to \$40,000. During January about 11,000 tons of ore yielded over \$120,000.

LINCOLN COUNTY

Troy.—During January the Snowstorm Consolidated treated 6500 tons of ore. Floods early in the month curtailed operations somewhat. Zinc concentrate worth \$8000 has been accumulated, and daily additions are up to 30 tons. No. 6 tun-

structed. The Seaboard Steel Co. takes all of this ore and hopes to get 200 tons daily.

ELKO COUNTY

Tuscarora.—This old silver district is again attracting the attention of prominent mining men. The rising price of silver has made possible the operation of many mines here. Last year the assessment roll of Elko county showed that work had been done on 132 claims at Tuscarora. This centre has a past production of \$50,000,000 and over \$10,000,000 was paid in dividends.

There are three groups of properties under separate ownership at present, and these represent practically the whole district. The first is the Grand Prize, idle at present, consisting of the Phoenix, Early Morning, Golden Treasure, New Housdale, and New Era claims. This group is owned by the Wheeler family, and Z. F. Wheeler of Tuscarora is in charge; the second is the Commonwealth, under option to the Stewart Mining Co. of Idaho, consisting of the Commonwealth, Silver King, Diana, North Belle Isle, Exter, May Queen, and McVystal claims; and the third comprises practically the remainder of the claims in Tuscarora, including the Navajo, Dexter, Young America, Elra, and Ecletic. This group also controls the Tuscarora water-works, which brings water from Taylor

TUSCARORA AND DISTRICT, ELKO COUNTY, NEVADA

nel has reached a depth of 1100 ft. T. L. Greenough is manager.

MINERAL COUNTY

Iron Mountain.—January shipments from the Intermountain Copper Mining Co. were valued at \$15,000 net. The last car of concentrate averaged 18% copper. Mill improvements raised the grade 3%. Ore is mined from the 400-ft. level. The 700-ft. level is under water, but may be re-opened in the spring.

SILVER BOW COUNTY

Butte.—The Granite Mountain shaft of the North Butte Mining Co. has been concreted from the surface to a depth of 3000 ft., also the surface equipment has been remodeled. The total cost was \$300,000. Hoisting will be resumed at once.

In the dispute over certain ore in the Black Rock claim, the United States Circuit Court of Appeals on February 19 affirmed the decision of the District Court of Montana and ordered a decree entered in favor of the Clark-Montana Realty Co. and the Elm Orlu Mining Co. against the Butte & Superior Mining Company.

NEVADA

CLARK COUNTY

Las Vegas.—The Manganese Association has been incorporated recently, with James McCoy as general manager and F. A. Stevens as secretary. Auto-trucks are hauling 60 tons of manganese daily. A standard-gauge railway is to be con-

canyon and cost over \$80,000, and the Jack Creek power-plant. The owners of this group are E. K. Stallo and Samuel Newhouse of Salt Lake City. A syndicate is now being formed to operate this property.

The dumps of Tuscarora represent a large sum of money. Nearly all of them can be made to pay by screening out the coarse material and working the fine. Some of the dumps are immense, the Navajo, of the third group, having upward of 300,000 tons, and the Grand Prize over 350,000 tons.

Good veins are known to exist in many of these mines. It must be remembered that it has been a long time since silver was at a price high enough to enable these mines to operate. Milling costs were high years ago, being about \$27.50 per ton. In the Grand Prize, at 780 ft. a vein is said to be in places 17 to 18 ft. wide that will assay 22 oz. silver and some gold. In the Dexter and Young America mines good ore-bodies exist, known to old-timers, and can be worked at a good profit today. Core-drilling is necessary in this district to prove quickly and cheaply what exists.

ESMERALDA COUNTY

Goldfield.—It is reported that rich ore is being opened in a winze in the Red Hills Florence mine. On February 14 about 100,000 shares changed hands, declining from 7 to 5c. each, due to lack of news.

HUMBOLDT COUNTY

Golconda.—An extensive deposit of manganese is said to

have been discovered near Adelaide canyon, 12 miles south of Golconda, by W. S. O'Brien, J. Tucker, and T. Tucker. The ore assays 51% metal, according to analysis made at Winnemucca.

LYON COUNTY

Yerington.—The Bluestone Mining & Smelting Co. is shipping 100 tons of ore daily to the Mason Valley smelter at Thompson. Development is said to have opened enough ore to supply a mill of 800 to 1000 tons daily capacity. A plant including two 8-ft. Hardinge ball-mills and flotation apparatus is to be ready by March.

NYE COUNTY

Manhattan.—Argument in the White Caps-Morning Glory apex suit was completed on February 14, and a decision was expected at an early date.

Tonopah.—The old Liberty mine, 20 miles north of Tonopah, has been re-opened by W. H. Aubrey, and at a depth of 60 ft. there is showing 10 ft. of ore assaying 60 oz. silver and $6\frac{1}{2}\%$ lead. This mine was opened to a depth of 700 ft. in the seventies.

WASHOE COUNTY

Virginia City.—Two shifts are working at 2000 ft. in the Con. Virginia, where low-grade ore was exposed years ago.

In the Mexican mine, interest centres around exploration at 2300 feet. A 10-cent assessment has been levied.

WHITE PINE COUNTY

Ely.—From the 160-ft. level of the Willow Creek Gold Mining Co.'s property 450 lb. of ore, worth \$2500, was shipped to San Francisco by express last week. The lode is 4 ft. wide, containing an 8-in. streak of rich ore.

NEW JERSEY

SUSSEX COUNTY

Franklin.—Results of New Jersey Zinc Co. during 1917 and 1916 are as follows:

	1917	1916
Net income	\$19,086,601	\$34,488,239
Dividends	12,600,000	26,600,000
Surplus	\$6,846,601	\$7,888,239

From the 1917 surplus of \$6,486,601 there was deducted \$4,381,650 as additional Federal taxes for the first and second quarters imposed by Act of October 3, 1917, thereby cutting the surplus to \$2,104,952.

NEW MEXICO

SOCORRO COUNTY

Mogollon.—The Socorro is opening the Consolidated and Gunboat mines by adits and is also driving the 700 and 1100-ft. levels of the Fanny mine. The Oaks Co. is starting a shaft in the Clifton adit under a slope from which it has been milling \$15 ore. The company is shipping from and developing the Queen vein in the Eberle mine 1500 ft. farther south; the last shipment milled over \$11. Mr. Peterson and associates are developing the same vein a mile farther to the south and have found good ore. The Queen vein crops strongly for several miles and varies from 10 to 30 ft. in width. Extensive development work is planned for this vein during the present year.

OKLAHOMA

OTTAWA COUNTY

Picher.—On account of finding a 25-ft. orebody in its ground, the National Lead & Zinc Co. has resumed milling operations north-west of Picher.

Quapaw.—The Big Three Mining Co. has sold 40 acres to Howard Paschal of New York for \$75,000, plus $2\frac{1}{2}\%$ royalty. The present shaft is to be deepened.

The Quapaw Mining Co. is to erect a mill on its 80-acre lease near the Lincolnville station, a mile south of Quapaw.

Drilling this ground revealed a deposit 20 ft. thick at a depth of 100 ft. No. 1 shaft has yielded 4000 tons of ore, which is ready for the new plant. A 5% royalty is paid the owners of the land.

Either a 250 or 400-ton mill will be erected by the Medical Mining Co., operating west of Quapaw. Twenty-five drill-holes showed good ore.

Tar River.—The 50-acre lease of L. P. Buchanan of Joplin, Missouri, near Baxter Springs, is developing well. Thirty drill-holes showed 10% ore.

Oklahoma City.—The Crescent Lead & Zinc Co., controlled by local people, will proceed with the erection of a mill on a 40-acre lease in the north-west quarter of the north-east quarter of section 33, and will bring the property to a state of production at the earliest possible date. The land has been prospected, 14 drill-holes having been put down, showing a good deposit of ore. A shaft is now being sunk. The land is near the Welch mines, which were sold last July for a price said to be \$2,000,000. The men composing the Crescent company are James Auderbach, Oklahoma City; W. A. Doty, Newkirk; S. Bowman, Durant; W. L. Townsley, Sulphur.

The Bethel Mining Co. is making improvements on 3 leases, the Bethel, the Domado, and the Croesus. Drill rigs are being operated on all the properties. Three are on the Croesus, three on the Domado, and one on the Bethel. Twenty feet of ore has been penetrated on the Bethel and the Domado leases, assaying from 8 to 15%. It is probable that mills will be built on each of the three leases. The Bethel mill has been down for some time and has been entirely overhauled. Among the improvements, 10 tables have been added to the sludge department. The Croesus has been overhauled also and a number of changes made.

TEXAS

BREWSTER COUNTY

Terlingua.—It is thought that if there should be no great drop in the price of quicksilver during the present year the production of this metal in Texas will show a considerable increase, according to the statements of men who are interested in the industry of mining and treating cinnabar ore in the Terlingua district. The production of the metal in this State last year was nearly double in quantity and nearly quadruple in value what it was for the preceding year. The Terlingua district gave a total yield of 10,759 flasks for 1917, compared to 6506 flasks for 1916.

Owing to the fact that the Terlingua district is situated 90 miles from the nearest railroad point, Marfa on the Southern Pacific, and that the district is a dreary inhospitable part of the upper Rio Grande border, there has been little prospecting for cinnabar ore. It is well known that the cinnabar-bearing formation extends across the Rio Grande into Mexico and that it covers a much wider area on the Texas side of the river than has been developed up to this time. The cost of getting in supplies is heavy on account of the remoteness of the camp from the railroad. The cinnabar claims that were located north-east of Boquillas some time ago are to be developed as soon as machinery and furnaces can be installed. The work of opening up the mines situated in Mexico, opposite Terlingua, will begin as soon as border conditions in that country become more settled.

UTAH

JUAB COUNTY

Eureka.—Encouraging reports came from the Zuma mine, where a winze below the 500-ft. level is in good ore. New machinery has been ordered.

Exploration is under way at a depth of 200 ft. in the Republic mine, in charge of E. R. Higginson. The upper levels produced some good ore some time ago.

During December the Dragon Consolidated shipped 8000

tons of ore, which is desired by smelters for its fluxing qualities. Below the 1000-ft. level a winze is down 600 ft. in new ground.

No. 1 shaft of the Iron Blossom is down 2100 ft., and is to be sunk deeper, according to Frank Birch, the manager. Monthly earnings are \$10,000.

Tintic.—During 1917 the Mammoth Mining Co. shipped 40,000 tons of ore worth \$1,250,000. Dividends absorbed \$400,000. Present weekly ore shipments are about 15 carloads.

SALT LAKE COUNTY

Alta.—At the recent annual meeting of the Michigan-Utah Con. Mines Co. all officers save one were re-elected. R. R. Van Valkenburg is mine superintendent, and R. A. Brown consulting engineer. The financial condition of the company is much improved.

SUMMIT COUNTY

Park City.—Ore shipments from this centre during January totaled 205 carloads, equal to 10,547 tons. The Ontario Silver company contributed 3533 tons; Judge, 2791 tons; Silver King Coalition, 2417 tons; Silver King Con., 936 tons; and Daly West, 633 tons.

WASHINGTON

FERRY COUNTY

Spokane.—The ninth annual convention of the Northwest Mining Association opened on February 12. There was a large attendance from British Columbia, Idaho, Montana, Oregon, and Washington. A large number of minerals was exhibited, also a moving picture depicted 'Spokane to the Bunker Hill & Sullivan.' A variety of subjects was discussed, including mining war-tax, mineral-land laws, production and prices of metals, leasing mineral lands, leasing coal lands, protecting investors in mining stocks, handling explosives, concrete in mine operations, acetylene mine lighting, give miners a square deal, what stimulates mining, mining legislation, value of the Mining Association, oil-fotation, and mine-safety work. Opposition to Government control of mines, unless an actual shortage of minerals develops under private management, was voiced. Government subsidies to encourage production of rare metals, the Federal control of custom smelters and metallurgical processes and patents, with prices fixed by Government agencies, were asked; and free admission of lead and zinc ores between Canada and the United States was petitioned for. Purchase by the Government of a quantity of silver at \$1 per ounce was endorsed, and the creation of a Federal department of mining, with a Cabinet member at its head, was asked.

The U. S. CIVIL SERVICE COMMISSION at Washington, D. C., announces an open competitive examination for assistant coal mining engineer, to fill a vacancy in the Bureau of Mines for service in the field, at \$1500 to \$2400 per year. The duties of this position will include assisting in the conduct of investigations relating to coal mines, particularly into the causes of mine explosions and other mine accidents, avoidable and unavoidable losses of coal in mining, and the method of remedying such accidents and losses. Applicants must not have reached their 45th birthday on the date of examination. Applications must be filed by March 19.

THE ENGINEERING COUNCIL OF THE UNITED ENGINEERING SOCIETY, New York, states that it has extensive lists and information concerning engineers in this country, and desires to know who have joined any kind of Government service and who are available for positions that may be open in connection with the Army and Navy.

A meeting of the New York section of the MINING AND METALLURGICAL SOCIETY OF AMERICA was held at New York on February 14. The speaker of the evening was Simon Lake, one of the original inventors of the submarine.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

F. L. RANSOME was at New Almaden this week.

G. W. HIND, of Abilene, Texas, is in San Francisco.

E. P. MATHEWSON is expected in San Francisco next week.

C. VEY HOLMAN has been appointed State Assayer in Maine.

J. H. G. WOLF has gone from San Francisco to Washington.

ROBERT F. LETTIS, of Lima, Peru, is on a visit to San Francisco.

E. C. HOMERSHAM has returned from Johannesburg to London.

J. A. REID, of Cobalt, Canada, was at Wickenburg, Arizona, last week.

DAVID J. PULLINGER has returned from Nicaragua to San Francisco.

GEORGE C. CARPENTER, president of the National Lead Co., Denver, is here.

HERBERT C. WOOLMER has left Moscow, Russia, and is now resident in London.

M. W. VON BERNEWITZ has resumed his duties as Assistant Editor of this paper.

H. H. NICHOLSON is examining zinc-lead properties in the Joplin district, Missouri.

F. C. FRENCH is now Captain in the Engineer Officers Training Corps at Camp Lee, Virginia.

THOMAS F. SHERIDAN, of counsel for the Butte & Superior Mining Co., is at the St. Francis hotel.

C. H. HAND, formerly of Butte and now living at Los Angeles, was in San Francisco this week.

RENO H. SALES, geologist to the Anaconda Copper Co., has been to the Black Rock district, in Arizona.

W. M. H. WOODWARD has been appointed First Lieutenant in the 512th Engineers, and is stationed at Camp Travis, Texas.

L. SIBLEY M. GARRISON, of counsel for Minerals Separation, is here with SETH GREGORY, the company's manager at New York.

H. FOSTER BAIN is returning from China to accept the position of assistant to the Director of the U. S. Bureau of Mines.

I. F. LAUCKS, formerly of Falkenburg & Laucks, has opened chemical and metallurgical laboratories at 99 Marion street, Seattle.

W. A. CATTELL, formerly consulting engineer in San Francisco, is now Major and has been assigned to active service at Camp Lee, Virginia.

W. L. PENICK, recently foreman of the experimental mill at Anoyx, B. C., has joined the staff of the Hardinge Conical Mill Co. at Salt Lake City.

CHARLES O'CONNELL has resigned as manager of the Tough Oakes mine to become manager of the Boston Hollinger, at Boston Creek, Ontario.

CHARLES L. HARRINGTON has resigned as superintendent for the Overall Mine Co. to become mine superintendent for the Schlesinger Radium Co. of Denver, with headquarters at Naturita, Colorado.

CHARLES EDWARD STUART, formerly member of the engineering staff for the American Smelting & Refining Co., is now Captain in the Engineer Reserve Corps, and has been assigned to duty in the 312th Sapper Regiment of Engineers.

THE OREGON SCHOOL OF MINES SOCIETY held a special meeting on January 28. Thomas Varley, superintendent of the Northwest Experiment Station, U. S. Bureau of Mines at Seattle, addressed the Society. He discussed in some detail the development and work of the Bureau, and gave a brief résumé of the conditions affecting war minerals on the Pacific Coast. About 40 members were present.

Book Reviews

COMPRESSED AIR PRACTICE IN MINING. By David Penman. Pp. 221. Index, 113 ill. J. B. Lippincott Co., Philadelphia. 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.75.

The value of this little treatise seems to be mainly for shop use. It gives the fundamentals of the subject of air-compression in simple language, discusses adiabatics, the compression curve, the expansion curve, the construction of the isothermal and the adiabatic diagrams, multiple-stage compression, and expansion, with examples. Efficiency of compressors and air motors is then taken up, and the indicator diagrams follow in a separate chapter, after which comes a discussion of reciprocating air-compressors, the turbo-compressor, and the general principles of transmission of power. There is more in the book, especially with reference to rock-drills and coal-cutting machinery. It is a handy work that will be appreciated by whom who wish a simple statement of the problems involved.

METRIC TABLES. By Guilford L. Molesworth. Spon & Chamberlain, New York, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, 75 cents.

This is the fourth edition of a vest-pocket booklet that will be particularly appreciated, now that so strenuous an effort is being made to introduce the metric system into this country. Opinions differ as to the advisability of compelling the use of the metric system, but it is certain that the acceptance of that system will widen rapidly in the next few years as a commercial necessity, in order to give us an outlet for our manufactures in other countries, where, to put it frankly, the inch and the foot are so great a nuisance that workmen object to handle anything which calls for repairs on the basis of English measures, for which no gauges are available in their shops. This little book is adapted for ready conversion of all weights and measures, and also has tables giving the relationships between kilogramme calories and British thermal units, and prices in francs and shillings per unit of weight and length. It is a pity that similar tables in terms of American currency were not added.

ELECTRIC FURNACES IN THE IRON AND STEEL INDUSTRY. By W. Rodenhauser, J. Schoenawa, and C. H. Vom Baur. Second edition. Completely re-written. Pp. 429. Index. John Wiley & Sons, New York, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$3.75 net.

This book was published originally in German, in 1911, and brought into English in 1912. The new edition covers the advances made to the date of publication, which is September 1, 1917. It is a book that has made a strong appeal, owing to the widening interest in the production of iron and steel by the electric furnace. The growth of the electric steel industry has been enormous in the United States in the last three years, so that we now manufacture more steel by that process than all the rest of the world together. The book is not a highly technical discussion, but is adapted for the average electrician, and is not complicated by the introduction of the calculus. It gives a historical review of the subject, the laws and fundamental principles of electricity, with special reference to the effects of the electric current in its application to furnace-work, it has an illuminating chapter on the power factor, and the alternating current theory in general. It discusses the principles of arc-furnaces, and then takes up the special types, such as the Stassano, Héroult, Girod, and the Rennerfelt. Chapter IX describes the induction furnace, after which follow accounts of the Kjellin furnace and the Röschling-Rodenhauser furnace, electric shaft-furnaces, and a general review of numerous other types. Part II deals with the prac-

tical operations, such as materials for construction, cost of operation, and the technique of the electro-metallurgy of iron and steel. As an introduction to the subject, it is undoubtedly one of the clearest statements at present available.

THE MINES HANDBOOK. Edited by Walter Harvey Weed. Vol. XIII. Pp. 1919. Ill., maps, index. The Mines Handbook, 29 Broadway, New York, 1918. For sale by MINING AND SCIENTIFIC PRESS. Price, \$10.

If the founder—Horace J. Stevens—of 'The Copper Handbook' were alive to see what has been evolved from his early efforts he would be astonished at the scope of the thirteenth issue, now known as 'The Mines Handbook.' It is rightly termed an "international edition," for while Skinner's 'Mining Manual' covers most of the British-owned companies, 'The Mines Handbook' describes the most important of these and all in North and South America. The new volume contains notes on mines producing antimony, chrome, copper, gold, iron, lead, magnesite, manganese, molybdenum, nickel, quicksilver, tungsten, and zinc; iron being the important new section added this year.

In most publications of this kind, companies are arranged alphabetically, irrespective of country or metal. Such a scheme is simple enough and requires no index, but conceals imperfections; also it was difficult for engineers and machinery manufacturers to study any particular group of mines. These faults have been remedied by a geographical arrangement and index, the latter being on tinted paper in the front part of the book. The new system is one of countries, states, counties, districts, and towns; and at a glance one is able to determine the success or otherwise of any properties. If the geology is not given for all mines in a district, probably its description will be found under one mine, which might serve the lot. Another new feature, and one that should be extended considerably, is the inclusion of 31 maps of regions and districts. These add greatly to the study of a company's condition. Between each country is a clear break; a neat arrangement.

Reviewing seriatim, we find the index complete and well presented. The glossary of mining terms—21 pages—contains all that the ordinary mining man requires; as also do the four pages on mineralogy. In Chapter III are 19 pages covering all copper-bearing minerals; a useful list. Inquiries are frequently made concerning some company that is either merged, dead, liquidated, dissolved, bankrupt, or the like, such being difficult to trace; but here we find a list of approximately 4500 concerns under this head. Anybody reveling in statistics will have ample to satisfy himself in the 96 pages of Chapter V. Data have been brought right up to the end of 1917 in many cases, while foreign trade in metals covers eight months. The accompanying comments are worth-while. From page 249 to 1864 are described the officers, financial details, property, geology, development, equipment, and production of 4661 of the leading—and small—companies of the world. The text ranges from one line to fourteen pages for each, and is not so dull as one would expect in such a publication, as abstracts are given from leading journals on technical considerations at many mines, which makes the work more useful than ever. Foreign companies are well represented, especially the Japanese. The final 12 pages contain a re-print of the editor's—Walter Harvey Weed—address on 'Copper in America' delivered before the Pan-American Congress at Washington, D. C., in 1916.

'The Mines Handbook' is well printed on thin paper, opens flat, and is properly bound. In spite of all care, typographical errors creep in, and we note incorrect spelling on pages 32, 271, and 1727; a line upside down on page 569, and one out of place on page 1354. These do not detract one hit from the value of this handsome and useful reference work.

THE METAL MARKET

METAL PRICES

San Francisco, February 18

Aluminum-dust (100-lb. lots), per pound	\$1 00
Aluminum-dust (ton lots), per pound	\$0 90
Antimony, cents per pound	15.50
Antimony (wholesale), cents per pound	13.16
Electrolytic copper, cents per pound, in carload lots	23.50
Electrolytic copper, cents per pound, in small quantities	25.12
Pig-lead, cents per pound	7.25-8.25
Platinum, soft and hard metal, respectively, per ounce	\$108-116
Quicksilver, per flask of 75 lb.	\$115
Spelter, cents per pound	9.50
Zinc-dust, cents per pound	17.50

ORE PRICES

San Francisco, February 18

Antimony, 45% metal, per unit	\$1.05
Chromite, 34 to 40%, free SiO ₂ , limit 8%, f.o.b. California, per unit, according to grade	\$0.60-0.70
Chromite, 40% and over	\$0.85-1.00
Manganese, crude, per ton	\$8.00-10.00
Manganese, basis 40 to 44% Mn and 8% SiO ₂ , cents per unit	70.00-80.00
Tungsten, 60% WO ₃ , per unit	76.00
Molybdenite, per lb., 85% MoS ₂	\$2.15

February onward, tungsten, molybdenum, vanadium, manganese, chrome, and ferro-alloys come under the license authority of the American Iron and Steel Institute, in so far as these ores are imported from abroad. Importer dealers and consumers are henceforth required to give a guarantee before material is released to them.

New York, February 14

Chrome: High-grade ore is scarce, and practically none can be obtained from California. Market price is anywhere from \$1.50 to \$1.75 per unit, f.o.b. shipping point, for material carrying over 45% Cr₂O₃.

Manganese: February schedule for domestic ore continues at the same prices as in January. The rainy season having ended in Cuba and Porto Rico, manganese shipments from there have been resumed.

Tungsten: All buyers of high-grade ore seem to have fully covered their requirements for the present, and no business in this class has been done during the week. A fair amount of other grades, however, found a ready market. Stocks in New York, in the Middle West, and in the West, have accumulated on account of freight congestion. On the other hand a cable has been received from Bolivia stating that a flood has caused a washout on the railroads, and this will probably curtail shipments from that country. It is possible that smaller shipments from Bolivia will offset the present accumulation of ore in New York—Charles Hardy's weekly report.

EASTERN METAL MARKET

(By wire from New York)

February 19.—Copper is quiet; lead is dull and firm; spelter is inactive though steady; platinum is unchanged at \$108 to \$110.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

On February 14, President Wilson approved an agreement reached by the War Industries Board and the producers of grade A zinc, fixing a maximum price of 12c. per pound f.o.b. East St. Louis, subject to revision on June 1. A maximum price of 14c. per pound for plate zinc f.o.b. at plants and 15c. per pound for sheet zinc f.o.b. at plants was fixed subject to the usual trade discount.

The following conditions were laid down: (1) that the producers of grade A plate and sheet zinc will not reduce the present wages; (2) that the Allies, the public, and the Government will be sold zinc at the same prices; (3) that they will take necessary measures to prevent zinc from falling into the hands of speculators who might increase the price to the public; (4) that they exert every effort to keep up the production so as to assure an adequate supply during the War.

Eastern Metal Market

New York, February 13.

An already dull and inactive market in metals has been rendered more uninteresting and featureless by the two holidays this week. Yesterday was Lincoln's birthday, which is always closely observed in New York and Monday was another 'fuelless' day which, it is hoped, is the last one. There was no business in metals done on either of those days, hence the period which this letter covers is really only four days—the last four of last week.

Copper continues to be dominated by Government regulation and orders which are doubtless large, but not made public.

Tin has been quiet again with transactions confined to futures, spot metal being unobtainable.

Lead continues inactive but firm.

Zinc is also lifeless and featureless, but steady.

Antimony is lower with little demand.

The iron and steel market has a more cheerful aspect because of the much milder weather all over the East, which has prevailed for several days. The derangement of the whole machinery of production and shipment was so complete that many days will be necessary for any approach to normal operations, even with no more severe winter weather. Excepting last October and November, each month since April last has shown a decline in iron and steel output, revealing the fact that causes go deeper than the weather. Steel operations in the Central West are generally at 60 to 70% of capacity, with some at less than 50%. The marked reduction in pig-iron output in the last six weeks indicates a possible shortage in the later months of this year.

COPPER

In a market devoid of normal speculation, because of fixed Government prices, there is naturally little to report except market development of interest to the trade in general. But with a Saturday followed by two holidays—fuelless Monday and Lincoln's birthday—the source of information is cut down to absolutely nothing. The mild weather of the last week has been a boon, and has mitigated decidedly the fear of a shortage of raw materials at the Eastern refineries. The entire situation is much better, and the hope is strong that it will continue to improve. There was a rumor that some jobbers had been cutting the official price of 24.67¢, but no confirmation of this is found; it is rather vigorously denied. The price of 23.50¢ for carload and larger lots still obtains, and supplies seem ample for all concerned. Production is on a large scale, that of the Anaconda company for January having been 24,984,000 lb., contrasted with 13,000,000 lb. per month last July, August, and September.

TIN

In the four days on which any business was done—Wednesday, Thursday, Friday, and Saturday—the market was quiet. On those days a little business was transacted in far futures; the total probably aggregated 400 tons. More business would have been done if there had been more sellers. One reason for a lack of sellers is the fact that some or many merchants have gone out of the tin business because of the difficulties and extreme uncertainties. It is stated that if they make a purchase at what appears will net them a fair profit, by the time they obtain the tin the profit has developed into a loss, because of commandeering, demurrages, or other reasons. There has been no further Government commandeering since that reported last week. Transportation difficulties, while eliminated to some extent by the milder weather, continue to interfere with the shipments of metal after it reaches New York, or in the journey overland. Arrivals to February 8, inclusive, total

250 tons, with the quantity afloat estimated at 5275 tons. The last cable from London, on the 8th, reported the spot Straits tin market at £308 per ton, an advance of £7 over that of the 5th, reported in this letter a week ago.

LEAD

The same situation prevails in the lead market that has been characteristic for some weeks—extreme quietness. There was a little better inquiry in the four market days which this report covers, but this statement is entirely relative. The inquiry was not brisk, but the market before this has been stagnant and dead. This better inquiry resulted in some transactions, mostly for nearby delivery, but the tonnage involved was not large. Today (Wednesday) the American Smelting & Refining Co. advanced its price 1¢, per lb., to 7c., New York; but no reasons for this step are yet obtainable. The outside market has been 7c., New York, or 6.85c., St. Louis, up to the present; but a higher level is probable soon, as in the past.

ZINC

The same lethargy that has hung over the market so long continues. Demand is generally light. The Government is quietly taking substantial quantities of zinc, particularly grades A, B, and C (prime Western); but these negotiations are not public. No decision has been announced as to a fixed price for grade A, and all business being done is to be settled for on a price to be agreed upon later. This question of a price for grade A has been up for over eight months, and there is some dissatisfaction because no settlement has been reached. On account of railroad congestion and delayed shipments of materials the market is perhaps a little stiffer, and the quotation for prime Western for early delivery is 7.75c., St. Louis, or 8c., New York, though these can be shaded possibly to 7.62½c., St. Louis, or 7.87½c., New York. Sheet zinc is \$19 per 100 lb. base.

ANTIMONY

The market is a little lower at 13.75 to 14c. per lb., duty paid, New York, for Chinese and Japanese grades for prompt or early delivery. Demand continues light.

ALUMINUM

No. 1 virgin metal, 98 to 99% pure, is quoted at 36 to 38c. per lb., New York, for prompt and early delivery, but there is no life to the market.

ORES

Tungsten: Railroad congestion has interfered with business considerably and until more essential materials are moved, now that better conditions prevail, the market will remain inactive. Prices are unchanged at \$26 per unit for scheelite, down to \$20 for poorer grades. Californian producers are reported to be asking \$30 for scheelite. Ferro-tungsten is unchanged at \$2.35 per lb. of contained tungsten.

Molybdenum: An active business is reported at \$2.15 per lb. of MoS₃ in 85% molybdenite, and some shipments are made by express to get around freight congestion.

Antimony: In this ore there is nothing to report.

Manganese: Quotations are unchanged at \$1.25 per unit, delivered at furnace for 48% material and better. According to newspaper report, Brazil has stopped exportation of ore for the time being, and, if this continues, a further rise in price for domestic manganese should be looked for.

Magnesite: Calcined magnesite is offered freely at prices ranging around \$35 per short ton, f.o.b. shipping point.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

BARBER-GREENE SELF-FEEDING BUCKET LOADER

The distinguishing feature of the B-G self-feeding bucket loader is the rotating double-disc feeder (patents pending) at the base of the elevator. The feeder does the work of two or three men and gives the machine a range that is otherwise impossible. It enables the machine to dig to a width of five feet rather than to the bucket width, and the operator consequently has little difficulty in keeping the loader continuously up to the capacity. The digging or feeding device consists of a pair of horizontal discs, set almost flat on the ground, but

speeds in either direction. A differential provides for turning sharp corners. A slow reverse-feeding speed is provided and a high speed forward for road traveling. Two intermediate speeds forward and the reverse enable the loader to be readily spotted on the job. It will handle crushed ore, stone, gravel, clay, coal, cement-clinker, and other materials.

INSULUMINUM

One of the interesting new things which the research laboratories of the General Electric Co. at Schenectady has developed in the past few years is a process for impregnating iron and steel, with an aluminum alloy. The resulting material is a rich ferro-aluminum, of great hardness, and possessing heat-resisting qualities much in excess of iron and steel. It is a discovery of the first importance. Since the close of the bronze-age iron has been used for ovens, utensils, and tools of every kind for all temperatures up to a dull red; but for higher temperatures there has been, even up to the present day, no cheap metal available. Manufacturers and users of a wide range of equipment called upon to meet unusual thermal conditions have been quick to seize the opportunity of increasing the effectiveness and durability of their units by the use of material treated by this new process. It was with a great deal of satisfaction, therefore, that the Diamond Power Specialty Co. was able to announce, a year ago, that in line with its established policy of developing and producing equipment only of the highest order, it had secured the sole right as lessee, from the General Electric Co., to the use of this process in the manufacture of soot-blowers. It seems proper to add at this point that no advantage has been

BARBER-GREENE LOADER

with a slight pitch toward the pile. The rotation of the two discs carries the material to the centre where it is picked up by the buckets digging from the smooth surface of the discs. The wide digging-face of this loader enables it to handle a large quantity of material with very little movement, and it also enables the machine to advance without obstruction into the pile. The construction of the machine enables it to use the disc-feeder to the best advantage. The discs deliver a large capacity to the bucket elevator and this, in turn, is of a size consistent with this capacity. It is designed for handling heavy materials and for severe service. The frame construction and the wheels embody strength; the chains and buckets are selected for wearing-qualities; and the drive is designed to enable the operator to keep the machine at productive work for the maximum amount of time. A direct-gear drive to the rear wheels propels the loader forward or the reverse, two

or will be taken of the fact that the exclusive right to this process gives the company a virtual monopoly, so far at least as successful operation is concerned, of certain classes of installations, and that units of Insuluminum (the registered trade-name of the new material) are supplied at merely a nominal advance over the extra heavy steel required in ordinary locations.

The originator of the new method, having in mind the heat-resisting qualities of the product, called the treatment 'calorizing.' The essential point of difference between the effects of this process and any hitherto used commercially, such as galvanizing or sheradizing, is that the insulating material is not imposed as a coating or skin (which may be chipped off) upon the surface of the metal to be treated, but, on the contrary, enters into intimate association with it, so that the whole outer zone of the body affected changes its composition. A

homogeneous alloy is formed, which cannot be destroyed except as the mass of which it is a part is destroyed. The richness of the alloy is proportional to the depth of impregnation, which varies with the length of time of the treatment.

A photo-micrograph of the cross-section of a calorized-steel tube shows clearly the diffusion of the aluminum into the steel resulting from a fairly prolonged treatment. On the outer and inner surfaces of the tube a thin film of alumina is formed, and the thickness of the metal is increased by this slight amount. Under this a wide band of ferro-aluminum is found. In the centre the steel remains unchanged. It is interesting to note the even depth of the penetration.

One of the first questions arising in connection with the adoption of Insuluminum to the Diamond soot-blower system with its ability to withstand the stresses of hard service. The mechanical properties of the new material had to be determined accurately. On this point the General Electric Co. stated: "The coating produced by calorizing is so hard that considerable effort is required to break through it with a file. Consequently, such scratches or scrapings as it receives in normal handling need not be feared at all."

To supplement this information the Diamond Power Specialty Co. conducted a long series of severe tests of Insuluminum tubes, subjecting the metal to bending, flattening, and hammering. The results proved the homogeneity of the mass, and its ability to withstand severe treatment without failure. While these experiments were under way, the National Tube Co. became interested in the new metal, and early in the present year subjected it to a series of tests. Their signed statement is as follows: "Our laboratory reports that the calorized coating on 2-in. boiler tubes which they tested, did not fail when these samples were subjected to the standard boiler-tube flanging, crushing, flattening, expanding, and ring-tests."

The conclusions to be drawn from these investigations are self-evident. Insuluminum units are guaranteed to be of homogeneous structure, capable of withstanding the severest conditions to which they may be subjected by the conditions of installation and operation. They will resist for an indefinite time the continued action of temperatures as high as 1000° C. or 1800° F. This is an exact statement of the heat-resisting quality of the new metal. Its importance is apparent from the fact that steel begins to burn. It is believed, at about 370° C. and nickel at 650° C. Both of these metals will bear considerably higher temperatures, of course, but the oxidation of iron and steel becomes pronounced at 500° C., and increases rapidly from this point on.

Every material has an oxidation point, and that of Insuluminum is around 1100° C. If the alumina-film is broken, scaling will set in at a temperature above 1050° C., but if the film is unbroken the scaling temperature will be higher. The high heat-resisting quality of calorized metal makes it much less subject to warping than cast-iron or steel. In only one instance has any serious trouble of this nature developed in a soot-blower system. In the case in question the purchaser insisted upon making the installation himself. He did not make it properly, failing to utilize all the supports provided, with the result that after exposure to high temperature one of the units warped. On the customer's complaint the company made an investigation, and decided to replace the warped unit with a new one properly installed. This was done and no further trouble resulted. The new unit is now in place and reported to be standing up satisfactorily.

The superiority of this new metal over iron and steel for unusual heat conditions has commended itself to a large number of well-known companies. The Dayton Company, Buffalo, N. Y., writes: "Calorizing certainly prevents oxidation, increases heat conductivity, and increases melting points. We find it very essential in the treatment of our gas-making retorts which are subjected to an oxidizing atmosphere at 1600

to 2000° F." The Westinghouse Lamp Co., Bloomfield, N. Y., says: "These calorized tubes are used in furnaces where the temperature is in the neighborhood of 900 to 1000° C. At this temperature, we get normally double to triple the life which we would obtain from ordinary wrought-iron tubes." The Denver Rock Drill Mfg. Co., Denver, Colo., writes: "By submitting the pipe (calorized pipe used as containers in their steel-carbonizing process) to temperatures of 1650 to 1700° F., together with wrought iron, which we ordinarily use, of the same shape, size, and thickness, the calorized material lasted very nearly ten times as long as the plain pipe."

As the dominant factor in the mechanical soot-blower field, it was natural that the Diamond Power Specialty Co. should be the first to develop a means of insulating units so that they might be exposed continuously to combustion gases at high temperature. The original means employed consisted of placing two extra heavy steel pipes, one within the other, the space between being filled with a non-conducting material. The unit proved successful for water-tube boilers, because being capable of withstanding high temperatures it could be placed at points of advantage in the passes where units of other systems would have been destroyed in a short time by the hot gases. As the result of the introduction of this system a thoroughly effective cleaning of the boiler was secured, and a host of friends was made for the Diamond blower. Soon after the calorization process was announced the company's engineers instituted an investigation, lasting many months, of the new material. In addition to the mechanical and thermal tests, trial installations were made in all the different types of water-tube boilers. The Insuluminum units were placed at points in the passes where the temperature ranged from 1800 to 2000° F. The need of blowers at these locations had long been recognized, but their application had been considered impracticable. Performances of the units were watched with keen interest for months, and there was no sign of scaling or disintegration from the long exposures to combustion gases at the high temperatures existing.

Diamond mechanical soot-blowers are the one known positive means of keeping the fire-surfaces of boilers and economizers clean. Their pre-eminence has been recognized by the United States government, the U. S. Steel Corporation, the Ford Motor Co., the Hudson Motor Car Co., Inland Steel Co., Standard Oil Co., and many more. Over 40,000 installations have been made in all parts of the world. At present, boilers in excess of a total of 500,000 hp. are equipped each year with these blowers.

OPPORTUNITY OF THE SMALL QUARRY

One period in the development of man is called the Stone Age, when pieces of rock were used to make cumbersome, but rather effective, mauls for cracking heads; later peoples used larger amounts of stone in various forms to build houses, temples, and tombs, and adopted somewhat more convenient methods of exterminating the unfriendly; today the use of stone is much more extensive, and single American quarries have been crushing and marketing annually heaps of stone that would shame in size the most stupendous pyramid or sacred temple of the ancients.

Crushed stone in one form or another is an important part of practically every class of edifice and public improvement. It is required in the construction and repair of streets, roads, railroads, wharves, factories, and buildings. The art of quarrying and preparing the stone has been highly developed, and millions of tons of crushed stone are hauled annually by the railroads to meet the large and increasing demand.

Practically all open-top cars suitable for hauling stone are now requisitioned for hauling coal and other bulky materials to supply the Army and Navy and the industries contributing to their immediate support and development. This will prob-

ably interfere with the shipment of stone for various purposes for some time, and many contractors have already suspended operations on road building and repair, bridge approaches and other work that should be pushed to rapid completion, because of the limited amount of broken stone available. Many of these contractors have in the past depended on stone shipped considerable distances. In the immediate neighborhood of the work, large amounts of suitable stone are frequently to be found, and the possibilities of opening small quarries, or of utilizing masses of boulders, are left undeveloped. In some cases this stone is as good, or better than the stone specified for the job. The reason for this neglect has been the greater economy and convenience in handling stone from the larger crushing-plants. At this time of limited shipping facilities, small portable crushers can be used in the working of the available stone to the best advantage, where the distances are so small that teams and trucks can be used in delivering the stone so that the jobs can be completed and others begun without delay. When small local quarries are near at hand they can in many instances be depended on for immediate delivery of small orders, and can be rapidly enlarged to meet the full requirements of the job. In other cases it will be necessary to develop entirely new faces, but, if the work is undertaken in time, they can be made to yield a sufficiency of stone with a minimum of delay and overhead cost. There is more need for improving our roads than ever before. In time of war road maintenance is an essential part of our system of national defense which must not be deferred. In the light of the priority rulings the supply of crushed stone for road-building is distinctly something to be undertaken by the small local quarry.

BOILER-ROOM MANUAL

'Finding and Stopping Waste in Modern Boiler Rooms' is the title of a practical treatise intended to serve as a reference manual to aid owner, manager, and boiler-room operator in securing and maintaining economy in the steam plant, which has been issued by the HARRISON SAFETY BOILER WORKS of Philadelphia. It is an exceedingly interesting and valuable book of 274 pages, with index and illustrations, and is not confined to the discussion of equipment manufactured by the company. The several chapters deal with Fuels, Combustion, Heat Absorption, Boiler Efficiency, Boiler Testing, and Boiler-Plant Proportioning and Management, with an appendix dealing with the Cochrane Meters. As an example of the scope of the discussion under these chapter-divisions, that on Heat Absorption covers heat transmission, conduction, convection, radiation, heat-transfer from fluid in a channel, economizers, air-heaters and superheaters, improving absorption, heating-surface and boiler-capacity, boiler settings, refractories and firebrick, soot, scale, softening feed-water, and feed-water heating. The method of treatment is seen from the following excerpt on the subject of feed-water heating:

Heating boiler-feed water by means of exhaust steam effects a saving of about 1% of fuel for each 11° F. rise in the temperature of the feed water.

Besides the fuel saving, heating the feed-water increases the actual steaming capacity of the boilers. The part of the heat required to turn the water into steam supplied before the water enters the boiler diminishes the work of the heating-surfaces, or if, on the other hand, the transmission of heat remains the same as before, more steam will be generated from the same heating-surface, and for the same amount of fuel and hot gases, where the feed-water is preheated. The increase in capacity is in nearly the same proportion as the fuel saving. About one-seventh of the fuel is saved by heating the water from 50° to 210° F., and the steaming capacity is increased by one-sixth.

The saving from an open heater is greater than from a

closed heater, since the heat in the condensate from the exhaust steam is wasted by a closed heater, while the open heater saves it. The closed heater also wastes the condensed steam itself, because in the absence of an oil separator it is not suitable as boiler feed, while the open heater makes use of this distilled water as boiler feed. To make 7 lb. of hot boiler feed the closed heater requires 7 lb. of cold water and 1½ lb. of exhaust steam, whereas the open heater requires only 6 lb. of cold water and 1 lb. of exhaust steam, assuming that the water is heated from 50° to 210° F. in both cases. This is an important consideration, especially in condensing plants, where the supply of exhaust steam from auxiliaries may be limited. At a matter of fact, however, while open heaters, in which the steam comes into actual immediate contact with the water, will raise the temperature of the water to within 1° or 2° of the exhaust steam temperature, closed heaters with ½ sq. ft. per horse-power, the maximum amount of heating-surface ordinarily installed, will not come nearer than to within 15° to 30° of the steam temperature, even when the surface is clean and the heater free from air binding. Accumulations of scale on one side of the surface and grease on the other cut down the heat transmission, while unless the heater has a large surplus of exhaust steam passing through it, air accumulates, blanketing and rendering inactive a part of the surface. The closed heater also does not provide for the elimination of the air and other gases driven off from the water by heat, as does the open heater. Recent researches have shown that the air in solution is the principal cause of corrosion in boilers and piping.

An open heater can be used as a catch-all for all available supplies of exhaust steam and hot water, such as drips and condensate, suitable for boiler feeding. If the amount of exhaust steam from auxiliaries is not sufficient to raise the feed-water to the desired temperature, steam can advantageously be bled from an intermediate stage of the main turbine, such steam working with much higher efficiency than that which goes through to the condenser. If, on the other hand, there is not sufficient boiler-feed water at certain times, as during periods of light load, to absorb all of the auxiliary exhaust, the surplus not required for feed heating can automatically be passed by a flow valve to an intermediate stage of the main turbine and utilized therein.

The subject of feed-water heating is fully treated in 'Cochrane Heaters for Steam Power Plants,' published by the Harrison Safety Boiler Works.

The Boiler-Room Manual can be had from the same company. It is listed at \$1.

COMMERCIAL PARAGRAPHS

A 391-mile run without mechanical trouble, and delivery of freight several days ahead of railroad schedules, was the recent performance of a 4-wheel drive truck of the DUPLEX TRUCK Co. of Lansing, Michigan. Gasoline used was 59 gal., equal to 6½ miles per gallon. Although the cost was \$56.11, against \$41.30 by rail, there was no cartage to pay at each end and delivery was quick.

Chain-driven motor-trucks and tractors are discussed in Bulletin 359 of the LINK-BELT Co. of Chicago. The firm states that it has been making chains for 43 years, and the 'T T' roller-chain is one of its products. Advantages claimed for chain-driven over gear-driven trucks are (1) higher mechanical efficiency; (2) less unsprung weight; (3) semi-elastic driving to protect the machine; (4) the chain receives the most wear; and (5) variable wheel-centres are possible. On the other hand the Link-Belt Co. concedes to the gear types the advantage of enclosed and automatically lubricated driving parts. The publication shows the solid roller, new curled roller, and offset link-plate.

The First Line of Defense

In any mine, mill, or smelter; on any water-supply line; at any saw-mill—the first line of defense against fire and decay is the CEMENT-GUN.

This gun sprays atomized "Gunite", (cement-sand mixture) under pressure, over any surface to any desired thickness. Test after test has shown that surfaces so protected are immune from attack by fire, insects, and weather conditions.

Investigation will prove the efficiency of the CEMENT-GUN for your own work.

CEMENT-GUN

As many as eight Guns are in use in some mines. They are in daily use on a hundred-and-one different kinds of work.

WAUGH "CLIPPER" DRILLS

Mounted on a column or tripod, they will easily outdrill any other drills of their size and yet are unusually economical of power. Unmounted they are without an equal as light utility drills.

The "Clippers" can be equipped for either wet or dry drilling and are self-rotating machines possessing great durability.

The chance of losing a hole is reduced to a minimum when using these drills, for they can be cranked or worked back while rotating at full speed, without danger of breakage. This means much saving in both upkeep and drilling. Indeed, they are the embodiment of rock drill efficiency.

EDITORIAL

HEARST'S camouflage campaign, ostensibly to raise funds for the re-building of French towns, is being rated at its worth, judging from the subscription list in his local journal of misinformation. To any lover of France the suggestion coming from Hearst is much like the driver of a garbage wagon advocating the re-building of a cathedral.

AT the annual meeting of the Institute at New York the amendment on membership requirements was passed by a vote of 1123 to 59. The election of officers gives Mr. Sidney J. Jennings as president, Messrs. Henry S. Drinker and Robert M. Raymond as vice-presidents, the new directors being Messrs. F. G. Cottrell, Hennen Jennings, George C. Stone, S. A. Taylor, and Arthur Thacher. We feel sure that the profession will take pleasure in recognizing the excellence of the selection made. Apparently that distinguished engineer and technical authority, Dr. Drinker, the president of Lehigh University, is to be the next president.

EXCHANGE with Argentina has been stabilized so that in our trade with that country the American dollar will have a value of 97 cents. The discount is equivalent to the cost of transferring bullion to the southern republic. The Banco de la Nación at Buenos Aires maintains a deposit of \$17,000,000 in New York against which commercial credits may be issued, and these transactions will be handled by the Federal Reserve Bank on the basis of par plus 3% commission. Under an arrangement between the United States Treasury Department and the Argentine bank a limit of \$40,000,000 has been fixed temporarily as a basis for stabilizing the exchange between the two countries.

JOHANNESBURG has been treated to an exposure of gold-stealing that has opened the eyes of mine-managers on the Rand to the loss caused by illicit dealings in gold by Indians, more particularly. One dealer appears to have sent \$580,000 to India in four months, and his books showed receipts for \$1,500,000 in a single month. The Transvaal law is stringent on illicit buying of gold and provides severe penalties for infraction, yet it appears that legal proof that the Indian offended criminally is difficult to obtain. We expect, however,

that means will be quickly devised for checking theft, for the Boers and the British alike do not regard larceny as in any way humorous or excusable, as has been done at Cripple Creek, for example.

IN our issue of February 2 we expressed agreeable surprise at the optimism of the British directors of the copper companies operating in Siberia in face of the news concerning the condition of general anarchy then menacing Russian industry even in the outlying portions of what was an empire and is now a region without orderly government. We note that news has been received in London through the British Foreign Office that the Bolsheviki have confiscated the property of the Kyshtim Corporation and declared it 'national' property, because the local management "refused to accept the control of the workmen's committees." A formal protest has been lodged through the British embassy at Petrograd.

PAPER shortage is said to have "hit the Congressional Record." We hope the shortage of print-paper may cause Congress to diminish the quantity of useless printed matter that is posted wastefully from Washington. A record of congressional proceedings is necessary, of course, but it should be a true record, not a scrap-book of speeches and statements that were never made, fortunately for all concerned. The amount of waste in the Government Printing Office is deplorable, and it sets a bad example to the State legislatures. For example, we receive circulars and pamphlets from the agricultural departments both of the Federal and State governments, only to be troubled to throw them unopened into the waste-paper basket. Much of it is designed to give cheap notoriety to subordinates and in the attempt to create the impression that a great deal of work is being done, so as to obtain appropriations for the department.

DOLCOATH is a mine in which Cornishmen all over the world take almost a filial concern, so that it will interest them to learn that the two companies controlling the Dolcoath and East Pool mines, at Camborne, have joined in purchasing the mineral rights of the Tehidy Estate, which is the landlord to whom royalties averaging \$42,790 per annum have been paid by Dolcoath since

1895. Of the area over which mineral rights extend 2161 acres are under grant to mining companies that have paid an average of \$89,175 per annum during the last seven years. The transaction involves 9000 acres, and the freehold of all damaged lands, for the sum of \$450,000. The two companies will divide the mineral rights to the land outside their present holdings and thus will obtain both scope and inducement for further exploratory work. It is considered, by those best informed, that this negotiation will prove to be one of the most important events in the recent record of Cornish mining. It removes an incubus that has weighed heavily on progressive development. To Messrs. C. A. Moreing and Oliver Wethered is due the credit for the deal, and we hope that both of them may have the satisfaction of seeing their sagacity crowned by a new era of profitable mining in this historic portion of the old county.

TAXATION of mines was the subject of a paper read by Mr. Henry Louis, Professor of Mining in Durham University, at a recent meeting of the Institution in London. He insisted that the methods of taxation were accountable, in large part, for the decadence of British mining, and then proceeded to lay emphasis on the folly of levying an income-tax on such a wasting asset as a mine. In normal times the income-tax does not weigh heavily on mining companies, but now that it takes 25% of the profit it is a depressing incubus. The inadequate allowance permitted for depreciation of machinery is another unfavorable factor. The subject is of more than provincial interest, for it concerns the multitudinous forms of mining enterprise having headquarters in London and operating mines in different parts of the world. Excessive taxation, some of it illogical, will render inadvisable the registration of companies in England and will thereby rob London of some of its predominant position as a centre of mining finance. The problem is to cause the mining industry to contribute its proper share of the money needed for the War without imposing burdens that will check the development of mines.

GERMANY'S heroic victories over the Russian rabble brings into strong relief the helplessness of the mob that undertook to stop the Prussian by much talking. Those that will not fight for freedom do not deserve to be free. "The good German sword is again at work," as Count von Westarp says, and the point of that bloody weapon has been thrust through the agreements of the Brest-Litovsk conference with a rip and a rent that have been heard from the Baltic to the Euxine. The anarchists that have volunteered to lead the Russian revolution are as helpless as puling babes before the German invasion because they themselves destroyed the discipline of the Russian army before they demobilized it. They can now no more re-mobilize it than they can restore the morale that they shattered by their subserviency to the German propaganda. They continue to make faces at the 'bourgeoisie,' meaning the professional classes and all those sufficiently intelligent not to approve of jump-

ing from the frying-pan of an imperial bureaucracy into the fire of an anti-social chaos. The Prussian and the Bolshevik typify respectively the Seylla and Charybdis between which democracy must steer. Highly organized tyranny and wholly unorganized tumult represent the extremes from which civilization has ever sought to escape. What a fate to be a Pole, a Lithuanian, or an Estonian today!

IN our last issue we referred to the lack of co-ordination in the duplicated enquiries made by the Geological Survey and the Navy Department into the conditions governing the quicksilver industry of California. We forgot to mention that just before these two investigations were started, a third had been made for the Bureau of Mines by Mr. Hennen Jennings. Again we suggest that time and energy be saved by the use of the telephone at Washington. This suggestion would appear to apply even to those in higher offices, for during the past week, we have been treated to newspaper announcement by the heads of the Food and Railroad administrations, followed by the publication of a correspondence that exhibited a curious lack of co-operation. The telephone, or a quiet interview, is preferable to the columns of a daily newspaper as a means of communication between the administrators of national affairs.

The Shift-Boss

Shift-bosses are useful and important men in the economy of a mine. We take pleasure in publishing the text of a short address on the duties of a shift-boss as delivered at Bisbee by Mr. Joseph P. Hodgson consulting engineer of the mining department of the Phelps-Dodge Corporation. The shift-boss is the boatswain of those that go down to the mine in skips. He is the non-commissioned officer upon whom so largely depends the morale of the crew. He is the link between the company and its employees. A mine cannot be well managed without the aid of one or more good shift-bosses. Poor ones will render futile the best efforts of a clever superintendent. The shift-boss selects the men for different tasks; he tells them what to do, and is able to show them how to do it. Being in close touch with the men, he is the first to know if trouble is brewing, if they are dissatisfied, or if they are unfairly treated—and he himself may be the immediate cause of trouble by treating individuals unfairly, showing favoritism, or exhibiting bad temper. Again, the shift-boss is expected to have a keen eye for ore, to see that the working-places are safe, and to report any significant changes in the face of a level or stope. He sees to the safety of the working-places, and is the first to give aid when accidents happen. To the young mining engineer the shift-boss looms large. In him the technical graduate finds a storehouse of valuable experience, and from him can be obtained the practical hints that no professor or book can furnish. The young man on the way to becoming a mining engineer is wise if he make friends with the shift-boss, for in him he will

find the guide and philosopher of the world underground. To the visiting engineer, inspecting or appraising a mine, it is essential to establish pleasant relations with the shift-boss, for from him can be obtained information of a most illuminating kind. A hint from a shift-boss may be worth as much as a thousand samples. Shift-bosses deserve cigars. Ignorant and loutish shift-bosses there are, of course, but they are rare, because men of such characteristics rarely hold the confidence of the management or the respect of the men. Not only has the standard of shift-bossing improved as mining has become more technical in method and more comprehensive in scale, but a start has been made in training technical graduates for this work of supervision, which affords a splendid training for educated young men possessed of the physique and experience that are essential for such a responsibility. The innovation may succeed, but we shall continue to think of the shift-bosses whom we have known, not technical graduates, but boss miners, quick-witted and strong-armed, keenly observant, good natured, and intensely proud of their mine.

Mexican Finance

When General Porfirio Diaz brought Mexico to order in 1877 he found a country that had plunged blindly through 55 years of virtual medievalism, after its liberation from the colonial exploitation by Spain, without ever having enjoyed opportunity for industrial development. Co-operative effort in manufacturing and commerce had no place in the national life; the people were individualists from necessity, with the good, and not a few of the bad, qualities that germinate in such a society. It requires generations of organized industry to change the spirit of such a people; their understanding of the possibilities of living by personal wit, bravado, and strength is larger and deeper than their faith in the artificial system of a highly developed state. Collective effort and dependence upon the machinery of banks and credits and distribution of commodities, regulated through commercial exchanges, can but slowly replace the more primitive ideas of self-reliance. Those who lived in Mexico twenty years ago will recall the struggles of the banks of issue to establish their currency in the confidence of the merchants. The working people, the petty traders, the forwarding agents that dealt with the freighters who distributed goods throughout the back-country for the most part declined to be paid in bank-bills. Hard money, the safe kind that would not burn, that would neither mildew nor fall to pieces when buried, was the only acceptable currency. The people retained vivid memories of the sudden descent of robber chieftains, of the sort that would have been called counts and barons six centuries ago, when cash must as suddenly be hidden. It was against these medieval suspicions of government that Diaz had to work, and he overcame them so effectually that the currency of nearly all the State banks circulated freely at par throughout the

Republic. It was a great achievement. The revolution, however, has whirled the people back into the epoch of self-reliance, of intense individualism, of distrust in government and refined schemes of economic organization. The good work of Diaz has been undone, and it happened before the habits of social co-operation had been firmly established. Most of the men of big business have become exiles; those remaining belong preponderantly to the uneducated classes, who are the most suspicious of all forms and systems, and confidence in the reliability of governmental promises has been shattered by the experiences of the last seven years. Carranza is laboring against greater obstacles than those that confronted the man who gave Mexico her first uplift. At least Diaz did not have to explain any failure of previous experiments to introduce the machinery of civilization. The country has returned to a hard-money basis, and the credit system has been largely eliminated. The effort to create a central bank of issue has been resisted by the Mexican congress. Gold and silver sufficient to guarantee a large issue is not available, and the plans of the administration are not such as to inspire confidence. The result of authorizing such a bank without ample gold reserves would be further complication of the difficult finances of the country. The public would distrust the bank-notes, and as these would be legal tender the first effect would be to cause the disappearance from circulation of the coin now serving the needs of business. A staff correspondent of the New York 'Sun' recently stated that "with an empty treasury, and no credit, Carranza cannot meet the expenses of the Government, and looting as a means of maintenance is scarcely less necessary to his generals than to Villa or Zapata." It is evident that foreign aid is essential for the reconstruction of Mexico. With funds available to meet the obligations of the Government, and with credit and commerce re-established, deliverance is possible. The opportunity lies open through a cordial understanding with the United States; but, for this, a change of attitude on the part of Carranza is requisite. While he is still under the influence of Germany to such an extent that he can telegraph birthday congratulations to the Kaiser "who celebrates his anniversary today with just cause for rejoicing," and more adulation of that kind, the case seems hopeless. The Kaiser left no doubt as to his interpretation of the message from the old cacique when he replied that he was grateful for Carranza's "very amiable telegram of felicitation on the occasion of my birthday." On the heels of this comes word of a new treaty under which Mexico would enjoy the privilege of importing foodstuffs and gold from this country, but the dispatches fail to mention reciprocal advantages that shall accrue to the United States, except the right to draw ores and metals from Mexico, which right has been enjoyed continuously since Carranza came into power. The omission to suggest adequate reciprocity is peculiar. Usually it turns out that we have been too good-natured, just as in the case of Japan, where our arrangement for the exchange of ship-plates for shipping failed to justify the

hopes of our Department of State. It is this easy inefficiency in diplomacy, and our tendency to effusive generosity as the big brother that have so often brought upon us the contempt of the Mexicans, who explain such tactics as an evidence of timidity on our part to deal firmly with their Government. It certainly would be an error to offer Mexico the gold that she so greatly needs unless it were to cement a union equivalent to an alliance. Such a step, even in a country where executive decrees are sanctioned by act of Congress, would be most unlikely without special legislative authorization, and no steps of that kind have been taken. Without an alliance the privilege conceded solemnly by a treaty would be tantamount to strengthening the Enemy and playing into the hands of the Kaiser. News from Mexico indicates that Carranza's authority is lessening; his own generals are not faithful to him; new revolutionaries are constantly entering the field; Pelaez, the friend of the Allies, who has protected the interests of the Americans and British in the Tampico oilfields against the Carrancistas, now has pronounced for the triumph of the constitutionalist cause in Mexico, and has sounded the call for a national revolution. Meanwhile the grafters are making a display of luxury and extravagance in the capital city such as was never seen before, and against it the wretchedness of the poor stands in more pitiable contrast. These are symptoms of a political condition that cannot long endure. We do not wish to see more revolutions in Mexico, and we would welcome an alliance that would ensure the cordial co-operation of the two countries, but while Carranza remains an unregenerate German sympathizer, while he tries to get underneath the agreements of this country and our Allies with Argentina for wheat, and while he showers his favors upon German corporations and follows the lead of German advisors in his financial schemes, and assumes a continuously antagonistic attitude toward America and her Allies, we are opposed to further bolstering of his regime. Friendly acts alone could justify such favors.

Rhodesian Mining

Recent unexpectedly favorable underground developments, including the discovery of rich ore, in several of the Rhodesian gold mines, notably the Gaika, Lonely, and Shamva, have stirred the London mining market to a pitch of enthusiasm that must be peculiarly refreshing during this period of financial depression caused by the War. The good news has moved our excellent little contemporary 'The Mining News' to comment on the causes assignable for the "relative failure of the Rhodesian mining industry," meaning the series of disappointments during the last five years that have caused the public to withdraw speculative support from the various surviving gold-mining ventures. Our contemporary imputes the "relative failure" to the lack of working capital and to "the desire of many promoters originally connected with the country to get rich quickly through

the medium of the share-market." This is said evidently with a proper regard for the amenities of polite journalism and a discreet recognition of the propinquities of Throgmorton avenue. The real cause is the loss of public confidence in the financial companies that promoted and controlled the various mining enterprises of Rhodesia, more particularly the Consolidated Gold Fields of South Africa, the Amalgamated Properties of Rhodesia, the Rhodesian Exploration & Development Company, and the various subsidiary development and exploration companies by which the chief controllers were able to disguise their market operations. Of these the first-named was the most reputable and is therefore chiefly blameworthy for the collapse of public confidence. In plain English, the winning of gold from the ore in the mines was completely subordinated to the share-market game, a game played with loaded dice in so far as the controlling directors and their friends on the inside obtained the earliest information from the mines and used it to buy and sell shares on the Stock Exchange. The Gold Fields company, and others in the same business, acted as 'managers' for various subsidiary mining companies and rented office-quarters, as well as the complacent kind of directors most useful for the purposes of their business. When a mine was floated in London they supplied the report of one of their own engineers and fed the press with their own puffs, when these were not written freely by editors that obtained an option on a block of shares. The gutter press of London is multitudinous and voracious, and it would not exist if shady finance did not find it expedient to provide frequent nourishment. Unfortunately not only did the 'managers', that is, the financial company that provided headquarters and a staff to the individual mining enterprise, gamble in the shares, but the mining engineers responsible for periodical reports of progress, and supposed by the public to transmit unbiased news concerning developments, did the same. Rhodesian mining decayed to the point of putrescence because it was sacrificed to share-dealing of an unsavory kind—unsavory because it was done by directors that were in the position of trustees and by engineers that were in the position of scientific witnesses. As surely as money spoils sport, so surely share-gambling corrupts the integrity of mine management. This is an old story and the telling of it may prove wearisome to those familiar with the conditions that we attack. The morale of Rhodesian mining has sunk low because those in control were hardly aware that some of the things they do are wrong, they have done them so often, and without punishment, that they have come to think of them as proper to mining. That is the pathetic feature of the position, and for it the financial press is largely responsible. Only an independent press can create healthy public opinion on such matters, and that is of slow growth. No new discoveries will justify the public in re-entering the spider's web of intrigue and chicanery for which Rhodesian mining is synonymous; a restoration of confidence will be justified only when clean management is assured.

PRIMITIVE FURNACE AND BLOWER USED AT KOLMEZI, IN THE BELGIAN CONGO

The U. V. X. and the Kolmezi

The Editor:

Sir—Your recent article on the U. V. X. bonanza, "the most remarkable discovery of ore made in recent years," suggests a reference to an orebody in Kolmezi hill, 20 miles west of the Lualaba river, in the Belgian Congo, the property of the Union Minière du Haut Katanga. This hill, first seen by white men in 1902, was a favorite place for natives to make copper, and its southern slope is covered with their workings, one of which is a trench over 1000 ft. long, 12 to 20 ft. wide, and 10 ft. deep. From a shallow shaft sunk near the middle of this trench, a cross-cut was extended south for 262 ft., of which 258 ft. was clean ore and the other 4 ft. in the barren sandstone of the foot-wall country, the line of division being sharply defined. From the floor of this cut a bore-hole was put down in similar ore, the strata dipping regularly 65° north for 147 ft., making, with 40 ft. of backs, a known depth of 187 ft., and the ore continuing below. The orebody for a length of more than 800 ft. has an average width of over 400 ft., thus covering an area of 320,000 sq. ft., or over five times the 62,400 sq. ft. of the 260 by 440 ft. of the U. V. X., but, as malachite is of less specific gravity than chalcocite, the tonnage for equal depths would be only three times as great. Sampling showed an average of between 15 and 16% copper, about equal to the U. V. X., and while large samples were taken to ascertain the contents of the two varieties of the ore, similar results were obtained from 26 samples regularly taken at 10-ft. intervals. The cut has also been sampled time and again by different visitors; it is almost a pastime there. Like results were obtained from a considerable tonnage passed through the Kolmezi smelter. This smelter is shown in Fig. 1. The waterwheel in Fig. 2 ran on bearings hand-shaped in Central Africa from bronze made by mixing Kolmezi copper with tin from a similar reduction works at Busanga, 30 miles to the north.

The U. V. X. bonanza has already made a number of

men rich, while from the longer known Kolmezi orebody no man has as yet received a single dollar, and no one is likely to obtain any for years to come, as there are a great many known copper hills lying east of it along the Katanga copper belt with prior rights to crawl.

J. R. FARRELL.

Oakland, January 28.

Misfires

The Editor:

Sir—I note in your issue of December 1, 1917, an article on 'Missed Holes and a Wet Shaft' by J. F. Harrington, and as we have had considerable experience with the Clover Brand fuse, I thought you might care to receive what we think might be one or two reasons for this trouble.

We had a similar case; the trouble could not be located for some time, and then we found that a poor set of fuse-cutters was being used, resulting in the fuse not being cut square and the powder-man was not pushing the fuse back into the cap before crimping. This correction diminished the trouble but missed holes continued. Finally we found that the fuse was sent down in a box on the cage and the wrappers got wet when lying in the bottom of the box. The powder-man put six rolls of fuse on a rod and started by cutting the ends from each, pulling them out the required length and again cutting all these lengths and repeating the operation until he came to the last of the fuse. He then cut all the longer lengths to the same length as the shortest piece, which left one length out of every six coils of fuse without having its end cut, and if this end had happened to be up against water, it left a wet end to go into the primer; hence a missed hole. We had this remedied and our trouble disappeared.

Another remedy which we have sometimes used, is to dip the fuse and cap into P. & B. paint rather than painting the fuse. The cap and about one inch of the fuse should be dipped into the P. & B. paint and with-

drawn immediately so as to take no chances on having the destructive liquid penetrate to the core, for should oil penetrate to the powder it would be destroyed.

Should the above not remedy the trouble, I would suggest that you secure a length of fuse from a misfire and remove the cap. You would then be able to ascertain where the failure occurred, whether at the end of the fuse which is inserted in the cap, or along the length of the fuse. When the fuse is thus opened it is easy to determine the cause for failure, namely, whether the powder-core in the fuse had been wet, or whether the fuse had the appearance of having been kinked sufficiently to destroy the water-proofing qualities.

Referring to the kinking of the fuse, I remember a case where the fuse was laced in the cartridge in such a manner as to open the fuse sharply at this point, weakening the water-proof covering. This trouble was eliminated by placing the cap in the side of the cartridge pointing downward at an angle of 45° and tying the fuse with a string to hold it in place, thus avoiding any kinking at this point.

FRANK GROCH.

Cobalt, Ontario, February 5.

Water in Stamp-Milling

The Editor:

Sir—Referring to the question of the amount of water required in stamp-milling, brought up by H. E. West in your issue of January 5, I think the following data concerning this subject may be of interest:

The Nevada Wonder Mining Co.'s mill (formerly the Churchill Milling Co.) is equipped with ten 1400-lb. stamps, one 6-ft. Trent Chilean mill, and one 5 by 22-ft. tube-mill. It was the original intention to stamp about 7½ tons per stamp per day, but later developments showed that the Chilean mill and the tube-mill had a greater capacity; in consequence the stamp-duty was increased until during the year 1916 better than 20 tons per stamp per day, actual running-time, was achieved, and during 1917, on a much harder ore, 18.72 tons per day was the record, counting the operating time only. During this year a number of tests was made relative to the amount of solution passing through the batteries per ton of ore, and all tests checked closely, showing an average of 2.6 tons of solution per ton of ore.

This figure corresponds closely with that given by Mr. West, and if I were to answer his question as to whether or not the tonnage could be further increased by the addition of solution, I would be inclined to state that a higher ratio of solution would not increase the tonnage proportionately, in fact, I do not believe doubling the solution would increase the tonnage 10%.

Using this amount of solution a low discharge is maintained and the size of the screens varies with the hardness of the ore from day to day, and it is not uncommon to find a screen on the batteries made of heavy wire with openings one inch in the clear both vertically and horizontally. At times, when the ore is softer, a screen

as small as one-half inch in the clear is used, the intermediate screen being one-half by one inch in the clear. As an illustration of the varying conditions, examination of the records will show that when the mill has averaged 170 tons per day for some particular month the daily tonnage made varied from 140 to 220, with still greater variations shown occasionally.

E. E. CARPENTER.

Wonder, Nevada, February 19.

Chinese Mineral Production

The Editor:

Sir—It is not generally known among foreigners that the Ministry of Agriculture and Commerce of China has been issuing annual statistical reports in Chinese during the last three years, and that the latest to hand, issued last year, is for the year 1914. Although discrepancies and omissions could be detected here and there, yet the ministry deserves credit in the endeavor to compile these valuable statistics, heretofore unknown in China, which will certainly improve both in form and in accuracy in the future. The value of the output of various mineral products, in terms of Mexican silver pesos, is as follows: Gold, 3,664,040; copper, 59,888; iron, 1,450,127; tin, 9,258,987; lead, 162,280; antimony, 1,061,710; cobalt, 360; manganese, 16,000; arsenic, 3480; coal, 17,268,103; nitrates, 3964; sulphur, 102,230; and tale, 28,480. The number of mines operating was 4444, in which 258,461 persons were employed. The value of the product per miner was \$93, against a productive value per miner of \$1062 in the United States in the same period.

Fish in Arizona

The Editor:

Sir—In your article on 'The Apache Trail,' in the issue for February 23, you mention the lure of fishing in the Roosevelt lake, and incidentally name black bass and carp as existing there together. The experience of pisciculturists has been that bass, which are noble game and fight hard when caught on the line, nevertheless do not long inhabit the same waters with the carp. These creatures, which are of German origin, seem to have adopted the slogan 'karpfen-teich über alles', and devour all the small fry of bass and trout and other species, until only carp remain. Is the world-war not in progress in the Roosevelt lake?

NATURALIST.

San Francisco, February 25.

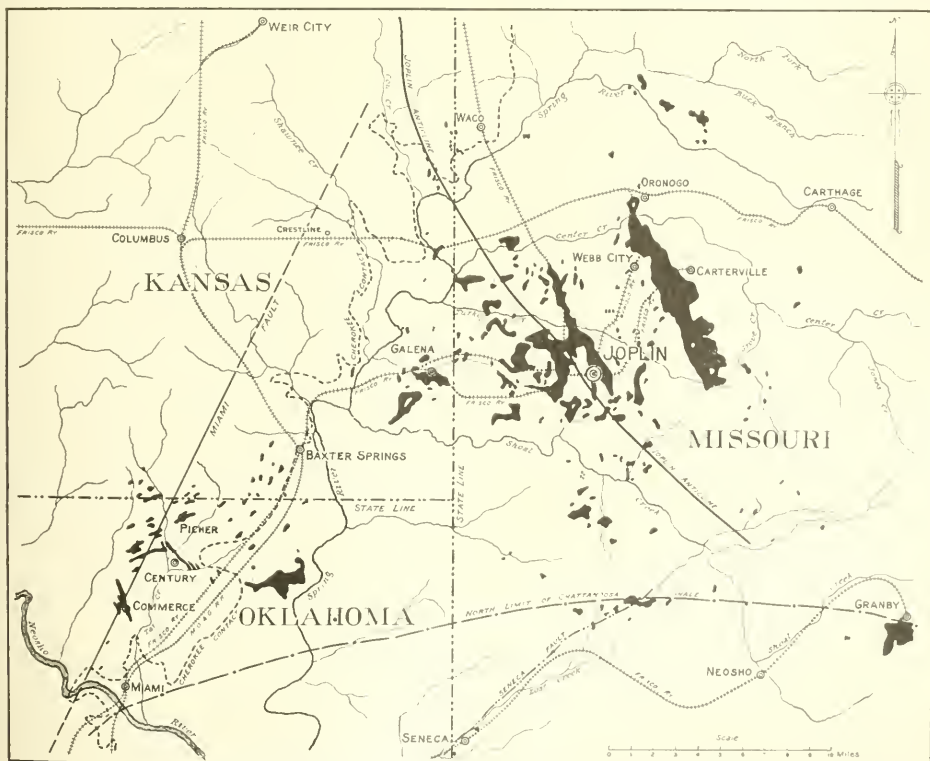

HEAVY solutions for separating minerals from ores on a commercial scale have been proposed by A. Nagelvoort, who recommends bromides of arsenic in carbon disulphide. The bromides are recovered by the solvent action of CS₂, and the excess of the latter is separated by distillation.

The Kansas-Oklahoma-Missouri, or Komspelter, Zinc Region — I

By T. A. RICKARD

INTRODUCTION. At the outset I confess a difficulty in selecting a name to describe the mining region that is the subject of this article. I might accept the hyphenated name used on the programme of the recent meeting of the American Institute of Mining Engineers; that was 'Joplin-Miami.' This name, however, is not satisfactory because Joplin constitutes only one district out of many comprised within the area in question; moreover, its importance is declining and its prestige is dependent largely upon the fact that it is a famous locality from which mining exploration has spread through south-western Missouri into north-eastern Oklahoma; also upon the fact that many of the men interested in the Oklahoma mines have their homes at Joplin and find it pleasant to use the Connor hotel as a social rendezvous. These con-

ditions will change when new towns and new hotels are built nearer the productive mines. The second half of 'Joplin-Miami' is even more objectionable; first, because the mines are not at Miami; second, because 'Miami' is the name of an older and more famous copper-mining district in Arizona. To give the name to two mining districts in the same country is only to invite confusion. There are ten post-offices named Miami, in the States of Arizona, California, Florida, Indiana, Kentucky, Missouri, New Mexico, Oklahoma, Texas, and West Virginia. This article will be confined chiefly to a description of mining activities in the sub-districts of Commerce and Picher, to which Century, Quapaw, and Tar River are attached; but the exploratory work already done indicates unmistakably that the ore-belt extends across the

line into Kansas, even as far as Crestline; therefore a comprehensive name is desirable; a regional designation is needed not only to include the older districts of Joplin and Webb City, in Missouri, with the newer and growing centres of activity around Commerce and Picher, in Oklahoma, but also the operations of the immediate future in Kansas; hence I have ventured to coin the name 'Konspelter', which gives the initials of the three States—Kansas, Oklahoma, and Missouri—prefixed to the trade name of the principal metal produced in this mining region.

The relative positions of the several mining centres are shown on the accompanying map. The town of Joplin is 360 miles south-west of St. Louis and 165 miles south-east of Kansas City; it is 34 miles from Miami, 24 miles from Picher, and 16 miles from Baxter Springs, the last being one of the oldest settlements in this part of the country. The area of the Konspelter region is 3000 square miles; from Springfield, in Missouri, to Miami, in Oklahoma, the distance is 100 miles; from Seneca, in Missouri, to Lawton, in Kansas, the distance is 30 miles. In days to come the limits of the known zinc-bearing area are likely to be extended even farther afield. During the period from January 1900 to August 25, 1917, this region, centring for many years around Joplin, had produced \$233,000,000 worth of zinc concentrate and \$44,000,000 of lead concentrate. During 1916 the combined output was worth \$35,955,318, according to the statistics compiled by Otto Ruhl for the recent meeting of the Institute.

During 1917 the total output of zinc and lead concentrates was as follows:

	Tons	Market-value per ton	Total value
Blende	409,114	\$70.52	\$28,469,637
Calamine	29,869	41.07	1,226,975
Galena	63,931	99.70	6,377,838

Mr. Ruhl informs me also that the 'ore-prices' for zinc-blende concentrate at the end of January 1918 were \$50 to \$67.50; for calamine, \$30 to \$35; and for lead 'ores,' meaning concentrate, \$85 per ton. The proportion of metal in these three products averaged 60% zinc,

40% zinc, and 80% lead, respectively.

The magnitude of the Konspelter industry can be indicated in another way. It is estimated that the capital invested in mining is \$33,400,000. The average profit per ton of concentrate may be taken at \$10; therefore a production of 3,340,000 tons of concentrate is required to return the capital. If an average recovery of 5% sulphide be assumed, then 66,800,000 tons of ore must be mined. Taking 15 ft. as the average working-face and allowing 14.1% of ore for pillars, then each acre will yield 45,000 tons of ore, so that to produce the tonnage calculated it will be necessary to exhaust the mineral wealth of 1485 acres per annum. This does not take account of interest; it assumes only the return of capital. To pay a reasonable interest the rate of exhaustion must be proportionately greater.

HISTORY. This is a comparatively old mining region. Lead was known to exist in south-western Missouri fully a hundred years ago, but the first mining was started in 1848 by William Tingle, in Jasper county, two miles from Joplin. This locality received but little attention at first, the principal activity being centred around Granby, where 300 shafts had been sunk by 1857. A smelter was built in 1852. The zinc mineral accompanying the lead was ignored at that time, because it had no commercial value. The Civil War interrupted work, but the completion of the first railroad, the St. Louis & San Francisco, stimulated development in 1865. About 1870 many discoveries of lead and zinc ores were made near Joplin and in 1872 the first zinc ore was marketed. By 1880 the Missouri production of lead ore had increased to 28,319 tons and of zinc ore* to 34,344 tons. In 1870 the ore-bearing ground was traced westward into Cherokee county, Kansas, and by 1877 Galena became prominent as a producer of lead and zinc. The first mining in Oklahoma was begun in 1891 at Peoria. In 1904 the first shaft in the Quapaw district was sunk and in August 1907 the first mill was completed. Railway connection

*The use of the term 'ore' as a synonym for 'concentrate' is general in this part of the world, so that it is impossible to tell whether crude ore, broken in the mine, is meant or the artificial product made by concentration in a mill. It is a stupid localism without logical excuse.

¹See editorial in M. & S. P. of November 10, 1917.

CHURN-DRILLS

THE PRAIRIE

with Miami, on the Frisco railroad, was made in the following year. By 1913 the productive ground had been traced, by drilling and shafts, to the Kansas line.²

The Missouri lead region is important in the history of American mining, not only on account of its production of metals but because it served as a school of mines for training many men that made their mark farther west. For example, George Hearst and David H. Moffat started their careers in the Joplin district.

The recent story of this mining region finds its central figure in a young mining engineer, Victor Rakowsky. As is not unusual in the history of mining, the human interest of the record is at least as impressive as the industrial result. Mr. Rakowsky was born in Minnesota in 1882, and graduated from the College of Mines at Houghton in 1904. In the fall of 1909 he came from Duluth to make an examination of the Commerce Mining & Royalty Co.'s property for A. M. Chisholm. At that time Commerce could be described as an unimportant zinc-mining district linked in a loose way with the well-known Joplin district; the one was in north-eastern Oklahoma and the other in south-western Kansas, the distance between them being 24 miles. Mr. Rakowsky's examination of the group of small mines at Commerce showed that three distinct ore-channels, or 'runs' of ore, had been developed at a depth of 100 ft. He made a careful survey and recognized the parallelism of these 'runs,' which might be described as lodges along lines of fracture in beds of chert. The deal on which he was asked to give an opinion involved the payment of \$175,000 for a half-interest, \$100,000 of this to be used for development and \$75,000 to go to the owners. He recommended the deal to his client, Mr. Chisholm, but financial conditions happened to be bad in November of that year, particularly in the timber and iron trades, in which Mr. Chisholm was heavily interested, therefore the business was dropped. Mr. Rakowsky kept in touch with the owners of the mines. Three years later, in July 1912, he obtained an option on the same property for \$1,250,000. By this time two more runs of ore had been found and 16 mills were in operation on the proper-

ties of the Commerce Mining & Royalty Co. and of its lessees. The option was taken for Charles Hayden, Charles M. MacNeill, and their associates, who formed a pool and delegated the investigation of the property to the American Zinc, Lead & Smelting Co. The examination was made by H. S. Kimball and R. H. Polhemus, who advised exploratory work and were placed in charge. Operations were concentrated on the extension of the known runs and as no more ore was uncovered during the four months of the option it was dropped after spending \$18,000. No drilling was done on the outside acreage.

Mr. Rakowsky remained at Miami, which is six miles south of Commerce. Still confident that the locality promised good opportunities for profitable mining, he secured leases from Clyde Fullerton and W. W. Dobson, who controlled ground in the northern part of the district along the Miami fault, the axis of the ore-belt. He leased 3500 acres on a royalty of 12½%, without a bonus, but with the privilege of testing the ground for a year, and longer if his work proceeded continuously. Fullerton and Dobson had obtained their title from the Indians owners of the ground, paying sums ranging from \$50 to \$200 per lease of 200 acres; they knew that Rakowsky had conducted the negotiations with the Commerce people and they were willing to give him a chance to promote a large enterprise. Rakowsky placed the business before O. S. Pieher, president of the Pieher Lead Co., a firm engaged in the manufacture of pigments at Joplin and now consolidated with the Eagle Lead Co. of Cincinnati. Mr. Pieher was anxious to increase his supply of lead product for the sublimation process and was already interested in the development of lead ore in the Joplin district; he knew, from his purchase of ores coming from the Oklahoma mines, that their output contained a proportion of lead larger than the Joplin ores; so he closed a deal with Mr. Rakowsky. The latter was put in charge of the exploratory work, being paid a salary and remaining under contract from October 1913 to January 1915, by which time he had proved 2,000,000 tons of 8% ore, that is, ore from which 8% of zinc and lead could be recovered in the mill. This successful demonstration of the local mineral resources was made on

²Silver, Copper, Lead, and Zinc in the Central States in 1914,' by B. S. Butler and J. P. Dunlop. U. S. Geological Survey, 1915.

the orebodies that are now supplying the Netta, Crawford, Bingham, and Whitebird mills.

In 1915 Rakowsky sold his equity and severed his connection with Picher. He then secured options in Kansas, on ground adjoining the Picher property, to the extent of 4500 acres on 20-year leases at 5 to 7% royalties. This business was submitted to J. L. Bruce of the Butte & Superior Mining Co. Mr. Bruce represented D. C. Jackling in the deal and formed the Miami Zinc Syndicate to conduct operations, which were commenced in June 1916. This work is still in progress and Mr. Rakowsky, I am glad to add, retains an equity in the property, so that he will participate in the success of it. The immediate result of exploration has been to prove the extension of the ore-belt from Oklahoma north-eastward into Kansas. Since the summer of 1916 Mr. Rakowsky has acquired leases along the projection of the Miami fault and in December of that year had secured 25,000 acres under first lease from land-owners in Kansas on royalties ranging from 5 to 7½% for a distance of 21 miles north-east of the Kansas-Oklahoma line. These leases have been transferred from the Jackling syndicate to the American Metal Co., which is now operating drills, and was expected to begin mining at three points before the end of 1917. Another suggestive discovery has been made at the extreme north end of the known zinc belt, near Waco, on the border of Kansas and Missouri, where a run of ore is being tested by local people, namely, P. B. Butler, T. J. Franks, and Frank Danglede. Mr. Rakowsky is also interested with O. M. Bilharz in the successful exploitation of the Bluebird, Shorthorn, and Chapman properties, which are now among the leading producers of the so-called Miami field. His faith has been splendidly justified and he has the satisfaction of knowing that the honorable part he has played in the development of this important mining industry is recognized by the community in which he lives.

It is worthy of note that the Commerce Mining & Royalty Co., which negotiated in 1909 for the sale of a half-interest at \$175,000, has recently* given an option on a part only of its holdings for \$5,000,000. Among other incidents of the boom I may refer to the good luck of Philip N. Moore, president of the American Institute of Mining Engineers. He and his friend C. P. Perrin acquired control of the Admiralty group, covering 100 acres, in 1915. They paid less than \$100,000 for the leases and 20 months later sold their rights through Mr. Rakowsky to Cosden, Aiken & Curtis, for \$600,000. In March 1917 Bulkeley Wells, representing the Metals Exploration Co., of Boston, bought leases on 180 acres, also through Mr. Rakowsky, for \$250,000. It is evident, therefore, that he has played a notable part in starting intelligent exploration and in the later transfers of property.

The mention of the Indian owners of the land draws

attention to an interesting feature of industrial development. In Ottawa county, the county in Oklahoma that is the scene of the principal mining activities, there are seven Indian tribes, but of these the Quapaws are the only ones fortunate enough to own mineral-producing lands. The allotments were made to them in 1896, in compensation for vague rights pertaining to them as aborigines. When they were restricted to this 'reservation,' each male adult received 240 acres. In 1897, by act of Congress, the Indians were permitted to lease their lands for mining purposes for a period of 10 years, but at that time there was no immediate prospect of using this privilege profitably; not until eight years later were rich deposits discovered under the surface of the prairie. The original leases were obtained for the purpose of drilling for oil, attention having been attracted by the tar seen on some of the water in this region. At that time the Quapaw reservation was the greatest producer of prairie hay in the country. The reservation extends southward six miles from the Kansas line into Oklahoma. In Kansas all the land is held by whites and no repetition of the Ottawa county experience is possible.

When ore was found a hundred feet below the surface the Indians were easily persuaded to grant leases on small royalties, say, 5% of the smelter returns; the local lessors were quick to sell their rights to speculators, who paid them absurdly small sums, from \$25 to two or three hundred dollars, and then in turn sub-leased the ground on royalties of 10 to 15% to real mine-operators. The Indians did not cultivate the land; for 50 cents per acre they would sell to a white man the right to cut the crop of wild hay that usually represented the only produce of the soil. Here and there, along the bottom lands, bordering the small and sluggish streams of this flat country, small areas of cultivation devoted to corn and sorghum might be seen, but in a broad way the region could be described as untamed prairie. For example, a State official³ purchased for \$250 the mineral rights on land belonging to Wah-tah-noh-zhe, a squaw, who had leased the land on a royalty to the Miami Royalty Co. This State official became the recipient of tribute while the Indian woman received \$250 in cash, which seemed to her lots of money and a more assured profit than the uncertain proceeds of mining operations that she did not understand. Her ground happened to become the site of the highly productive operations of the Turkey Fat mine, which paid the State official \$100,000 in royalty in a short time. Such impositions on the ignorant red people are no longer permitted; now their business is supervised and they are protected by a Federal agent. For several years the Quapaws were the only tribe of Indians that did not have to submit their arrangements, for disposing of land, to the Secretary of the Interior. This was a 'joker' perpetrated by ex-Governor Crawford, of Kansas, and A. B. Abrams, of Baxter Springs, a New York Indian with Hebrew blood. Abrams had managed

*This was written last November. A delay in obtaining supplementary data has prevented the prompt publication of this article.

³A Mine-Ownng Tribe of Indians,' by Lucius L. Wittich. M. & S. P., July 17, 1915.

to lay hands on 1700 acres of land in north-eastern Oklahoma and had become secretary of the Quapaw tribe. The ex-Governor secured 160 acres of land at Lincolnville, on which tract the rich Omaha-Petersburg mine is now situated.

Among the transactions worthy of mention, as illustrating the easy pickings available on this ethnic island of real Americans, I may mention how Harry Crawfish, a buck, sold for a song his mineral rights to the ground on which the Picher Lead Co. has developed several splendid mines. For a few hundred dollars Julia Greenback, a squaw, disposed of a lease out of which the Lost Trail mine has won zinc-lead ore to the amount that under a fair royalty would have yielded her \$20,000. Netta Trak, an Indian girl, owned an allotment of 200 acres; this was bought at auction in 1911 for \$9200, or \$46 per acre, by O. J. McConnell, associated with W. B. Thompson. The purchase was subject to a lease at 6% royalty payable to McConnell. This lease was sold on a 12% royalty to O. S. Picher, the fee simple being sold by McConnell to others for \$200,000, or \$100 per acre. The Netta is one of the most productive mines in the district.

In course of time, under the tutelage of their protector, the Federal agent, the Indians learned how to take advantage of the opportunity given to them by a bountiful providence, assisted by the U. S. government and the intelligent energy of the white miner. Benjamin Quapaw is receiving \$20,000 per month as royalty from ore mined under his allotment of 200 acres. Emma Gordon, who owned a similar allotment, married a 'mucker,' Hiram McBee, a Scot, who had been 'fired' from a mine working on that particular allotment. When he married the bronze landlady he did not revenge himself on the mining company; on the contrary, he conceded a full extension of the lease. He is dubbed "a real gent from Oklahoma." His income is \$25,000 per month, the tribute on a 20% royalty. The half-breed to whom Mr. Moore paid \$6000 royalty per month bought farm-mortgages in Kansas and two automobiles. These Indians are great motorists, in the sense of owning cars. The story is told that Jim Good Eagle bought a six-cylinder car at Joplin. A few days later another Indian went to the same agent and asked: "Jim Good Eagle, he buy car how many cylinders?" The agent said, "Six." To which the Indian replied, "Jim Good Eagle him no good; got no money; I buy nine-cylinder car." During the meeting of the Institute in this district early in October it was arranged that the Indians should give a dance on the occasion of a breakfast that was served on the Blue Mound, a hillock from which a good view of the prairie and its new mining industry could be obtained. The Indians came in blankets, but they drove their own high-power cars. Somebody exclaimed, "Poor Lo is riding on high." Shades of Alexander Pope!

Lo! the poor Indian whose untutored mind
Enjoys the tribute from another's find;
His soul proud Science never taught to stray
Beyond the zinc-ore price of yesterday.

SCENERY AND ROADS. The view from the top of the Blue Mound near Picher reminded me of looking upon the Sons of Gwalia mine and its environs as seen from Mount Leonora. Indeed, there is much about this region to recall Western Australia. The country is flat; it is dusty; the roads follow the section-lines, so that straight vistas are frequent, like the clearings that follow telegraph lines across the Westralian desert. They form aisles through the stunted forest—oak and elm, between Picher and Joplin—mulga and titree between Coolgardie and Menzies. The excitement of successful mining furnishes the electric atmosphere common to both regions; in both a few aborigines remain to remind the white man that he is an intruder, but the aboriginal American is as much superior to the Australian black as the conditions of life generally are more favorable on the prairie than in the desert. In 'W. A.,' as they call it there, we had to get our drinking-water by distilling the brine of shallow wells; in Oklahoma good water is plentiful, even if anything more potent is under prohibition. The scenery, if alike in its flatness and its stunted forest, is more urbane near the zinc mines than the thinly veiled aridity of the Australian hinterland, in which so many men have died of thirst in their hunger for gold. When I was in Western Australia the ship of the desert, the camel, was the most picturesque means of transport. In the Komselter region the motor-car is supreme. Three hundred taxicabs ply between Joplin and Miami; they bring 3500 people to Joplin on a Saturday night, many of them to the 'Connor,' which was built out of royalties by an Irishman that perpetuated his name honorably by building a handsome hotel. As for automobiles, there is an endless stream of them on all the principal roads. They pass at the rate of one car per minute; the main streets of the little mining settlements are cluttered with them; it is estimated that 2500 cars per day make the 24 miles between Joplin and Picher in 90 minutes. No wonder the roads are dusty, for they spread over the prairie wherever convenient. It is true, a beginning at road construction has been made in the environs of Joplin, and I am told that large sums of money have been voted to build a real road from Joplin to Miami, but in October last this improvement was still in the lap of the future. Meanwhile the mining industry suffers from being conducted 40 miles from the business centre; the managers travel in open touring-cars over the rough and dusty roads, injuring their eyesight and returning in the evening covered with grime, burnt by the sun, and buffeted by the wind of rapid transit. The technical staffs come into town on Saturday afternoons and return to the mines at 10 o'clock on Monday morning; the loss of time and energy due to this migration, daily for some, weekly for others, is a serious tax on their efficiency. An electric trolley-line is being built; this will be a boon. A system of light electric railways along the mining belt should be useful and profitable. These will help, but it is obvious that the technical men should live nearer the place of their work.

(To be continued)

V-Notch Weir Measurement

By D. ROBERT YARNELL and G. A. BINZ

*Weirs of various types are familiar to hydraulic engineers, and employed by them for the measurement of the flow of streams and of large volumes of flowing water. Fig. 2 shows a comparison of the flow-curves obtained when using various types of weirs. The rectangular form is most popular for large flows at a rather constant rate. It has been found less suitable for boiler-feed measurements, because different co-efficients have to be used for different ratios of width to height, and because the rectangular notch furnishes small motive-power at low rates of flow. The V-notch obviates both these objections. Its accuracy is essentially the same at all rates of flow. The curve also shows that, at low rates of flow, the head increases rapidly for small increments in volume. The V-notch is therefore an ideal weir for boiler-room measurements, and has become universally adopted for this purpose. Measurements of flow by means of the V-notch are based upon the well-known formula:

$$Q = KXH^{\frac{5}{2}}$$

Q = quantity flowing in a unit of time.

K = a constant.

H = height in inches of liquid flowing through weir.

The flow, therefore, is not directly proportional to the head, and some compensating device must be embodied in the recording-mechanism, if, as is desirable, the recording member shall travel equal distances on the chart for equal increments of flow. Various methods have been proposed with this in view, and a few of the more important ones will be briefly described. These methods may be divided into the following groups:

1. Instruments which use a plain float, and employ some intermediate method for correcting the travel of the pen on the recording-chart.

2. Instruments in which the compensation is provided in the shape of the weir, or where a float of special construction is used to secure equal rise for equal increments in flow.

3. Instruments operated electrically.

4. Instruments which weigh the liquid.

Commencing with group No. 1, probably the fore-runner of the best-known V-notch meters was that designed by James A. Gardner and built by the firm of Glenfield & Kennedy, Ltd., of Kilmarnock, Scotland. The idea underlying the construction of this meter is as follows: The length of a pendulum H , which controls the escapement of the integrating device, is made to vary as the $5/2$ power of the head of liquid in the notch. This is accomplished by causing the suspension-carriage E

of the pendulum to ride on a cam D , made to rotate as the float rises and falls. The device is so adjusted that there is no movement of the integrator when the float is at zero. As the float rises, the pendulum is shortened and the clock-escapement, which it controls, runs more rapidly. No chart-record is provided. Great delicacy is probably the principal disadvantage of this ingenious design. Next is the Lea meter. With this a cam is interposed between the float and the recording-chart. The cam is in the form of a drum carrying a screw-thread with variable pitch so calculated that the pen will be caused to travel equal distances on the chart for equal increments of flow. Another meter which uses this method of correction, but employs a spiral groove cut upon the surface of a flat disk, is the Cochrane (Fig. 4). The float is suspended from the cord S wound around drum B and counterbalanced by weight W . The cam-disc is mounted on the same shaft B and rotated when the float rises or falls, thus moving the carriage D to which the recording pen and integrator are attached.

Another group comprises those in which the correction, necessitated by the fact that the quantity of water flowing through a V-notch is as the $5/2$ power of the head, is made directly by shaping the weir or the float employed. One of the earliest methods of this kind is the weir designed by Wilfred Yorke, an Englishman (Fig. 5). This is so designed that the area varies as the square root of the height, and therefore the quantity of water flowing varies directly as the head. It has been found in practice that this weir cannot be shaped in accordance with calculated curves, as the varying effects of contraction and other disturbing factors have to be taken into consideration. It is therefore made in accordance with empirical determinations. The same principle is employed in a weir formerly manufactured by the Kennicott Co. (Fig. 6), where the water falls through a specially shaped slot, and for equal divisions of head A , B , C , D , and so on, the area added for the passage of water to the interior of the weir grows progressively smaller as the head increases. Both of these were found in practice to show considerable inaccuracy at low flows. Of meters in which the compensation to the chart-reading is obtained by employing a specially shaped float, probably the earliest was invented by J. W. Ledoux and built by the Simplex Valve & Meter Co. (Fig. 7). In this meter the buoyancy of the float is successively changed by causing the lower conical portion of the float to displace a varying quantity of mercury contained in M . In this way the effective weight of the compound float-system is successively decreased in such manner that the float will travel equal distances for equal increments

*Abstract: Proceedings Engineers' Club of Philadelphia from paper read before the Philadelphia Section of A. S. M. E., April 1917.

FIG. 3. RECORDING MECHANISM OF LEA METER

FIG. 5. THE YORKE INVERTED WEIR

in flow. Another form employing this principle of changing buoyance is found in the ingenious design by E. G. Bailey, of Boston. Here two displacement-bodies are used, suspended on opposite ends of a scale-beam that is pivoted on knife-edges. The two bodies are so adjusted that they rest on the surface of the water when no water is flowing through the notch. In this position both bodies are of equal area, displace equal volumes of water, and are therefore balanced. The cross-section of one of the bodies increases upward, whereas that of the other diminishes. As the water rises they therefore displace different volumes of water, and one will sink lower than the other before equilibrium is restored. A turning motion of the scale-beam results, which is transmitted to the recording chart. By shaping the contours of the two bodies, their motions are made to conform exactly with the $5/2$ -power curve of flow.

Of electrically-operated devices, only one has come under my notice; namely, that proposed in 1914 by Rateau, the inventor of the Rateau turbine. The head, in this case, is measured by the difference in level in a mercury U-tube. The leg in which exists the lower level carries a resistance-element, such as a high-resistance wire wound upon an insulator. This element is made part of an electric circuit in which is included a special differential millivolt-meter. As the mercury rises and falls in the leg of the U-tube, more or less of the resistance is cut out of the circuit, and the amount of current flowing may be caused to vary in accordance with the curve of the rate-of-flow.

The last group of meters comprises those that weigh the water as it flows through the weir. It must be conceded that, so far as the operation of a power-plant is concerned, this has much to recommend it, seeing that it gives its information directly in pounds of water. It will be seen, however, that the task of weighing the flowing water is difficult, necessitating a complicated form of apparatus. A typical example is the meter made by the Hoppes Manufacturing Co. (Fig. 8). This consists of a weighing vessel *W*, of special shape, suspended on a spring-scale. It has flexible connections to the weir-chamber *A* and to atmosphere *B*, and is so arranged that the scale is balanced at zero when no water is flowing through the notch. As the water rises in the weir, it also flows into the weighing-vessel and, owing to the special shape of the latter, pulls on the scale in exact proportion to the rate of flow.

In the Lea meter, as built today, the water to be measured enters the inlet-compartment of the steel or cast-iron tank, through a balanced control-valve, passes under a baffle into the approach-chamber, and thence through the V-notch weir into the large storage-compartment below. A pipe connecting with the bottom or end of the storage-chamber takes the water to the feed-pump. This design of tank, with a storage-chamber extending the full length under the inlet and approach-compartments, is patented. It possesses several notable advantages. It provides an exceptionally large volume of water for pump-storage, a long approach to the weir insuring accu-

rate measurements, and, moreover, by regulating the inlet with a float or bucket balanced upon this large pool, it is possible to secure easily readable charts. One corner of the inlet-compartment is partitioned off to form a still-chamber for the float. This chamber is connected with the weir-compartment by a small opening protected by a strainer. A very large and powerful seamless copper float rides upon the surface of the water in this still-chamber, and conveys its motions to the recording instrument mounted on the tank. In order to secure equal divisions on the chart, the recording-pen is not attached directly to the end of the float-rod, but an ingenious compensating mechanism is interposed between these members. As a check upon both the recording and the integrating mechanisms, a scale is fitted into each instrument, on which a pointer, attached to the end of the float-rod, indicates the height in inches of the water flowing through the notch at any time. By inserting this figure in the formula heretofore given, the accuracy of the instrument may be readily checked at any time while in normal operation. One American development of metering feed-water with the V-notch deserves brief mention. This is a metering heater, consisting in the standard Webster open feed-water heater which is combined with the Lea meter, the water, after being heated by the exhaust-steam, passing through an outside connection and the usual balanced control-valve, to the metering section. A considerable saving in floor-space and a conservation of heat-units result from this combination.

A Lea recorder was installed in the hydraulic laboratory of the University of Pennsylvania, directly connected to the cylindrical steel pressure-tank. This tank was over $5\frac{1}{2}$ ft. diam., and 37 ft. high. A stand-pipe with numerous overflows was provided, by means of which the head on the discharge-pipe could be varied at will by 2-ft. intervals. The meter discharged into an open flume, which carried the water to the large weighing-tanks on the floor below. These tanks were of steel, and had a capacity of about 15,000 lb. each. They were supported on accurate scales, sensitive to a weight of 5 lb. An efficient system of hydraulic valves allowed instant change from one tank to the other. The tanks could be emptied in 35 seconds. A hook-gauge was attached to the weir-chamber of the meter, and independent readings were taken every five minutes. The temperature was recorded on the same chart as the water by means of a recording thermometer fixed in the meter-case and checked at frequent intervals by a mercury thermometer. All readings were double-checked. A varying flow was obtained from practically zero to a considerable overload, thus reproducing power-plant conditions. The results are summarized below:

Total water weighed, pounds.....	154,559
Area of chart by planimeter.....	4.23
Scale of chart.....	36,312
Total water by chart, pounds.....	153,599.76
Error of chart-record against water weighed, per cent.....	0.62
Total water by integrator-reading, pounds.....	156,500
Total error of integrator, per cent.....	+1.256

FIG. 8. HOPKES RECORDING SCALE

As pointed out by J. W. Ledoux, it is not generally realized, even today, that the measurement of water flowing through a V-notch is an exceedingly difficult problem. While there are a number of practical, and reasonably accurate, meters available in the market, all of them are capable of improvement. The results of the test given above show a high degree of accuracy. It should be

noted that such closely correct measurement might not be obtained when the meter was running at a constant rate within 1% of the maximum flow.

FLUO-APATITE has been made synthetically by fusing sodium phosphate with fluorspar, and also by heating calcium phosphate with potassium fluoride and chloride.

Mining Conditions in Chile

By FRITZ MELLA

The year 1917 has witnessed no development of new mining enterprises of note. In copper, the Chile Exploration Co. at Chuquicamata, and the Braden Copper Co. at Rancagua, are of course by far the largest producers in Chile, the former with an output of about 4000 tons of electrolytic, and the latter with 3000 tons of blister monthly. The Braden company has under construction a new reduction plant with a daily capacity of 10,000 tons of ore, and Chuquicamata will increase the present 10,000-ton plant to 30,000 tons. It is of interest to observe that, with the gradual improvements made in the crushing and chlorine-elimination departments, as high as 13,000 tons of ore has been put through the Chuquicamata plant in 24 hours, and, were it not for the fact that the shortage of fuel-oil on the coast is restricting operations, this plant should easily handle between 11,000 and 12,000 tons of ore daily.

The Catemú and Naltagua smelters near Santiago, both operating with French capital, are producing from 250 to 300 tons each, of blister copper monthly, chiefly derived from ores produced from their own mines. Both of these companies recently commenced smelting in modern reverberatories, fired with coal-dust, Naltagua having two 5-ft. furnaces and Catemú one of like dimensions, although the latter company has an 80-ft. furnace under construction which it is hoped will be blown in shortly. The furnaces are running satisfactorily, and as they are equipped with waste-heat boilers, a material decrease in smelting costs, as compared with their blast-furnace practice, should be effected. The Catemú company is successfully floating its low-grade ores from the Los Mantos mines in an 80-ton plant. Also a 50-ton flotation unit for handling the ores from the Melon district is being erected at Chagres, adjoining the smelter site.

Other custom smelters operating are the Panulcillo, owned by the Central Chile Copper Co., the Guayacán at Coquimbo, recently acquired by the American Metal Co. from the Cia. Chilena de Fundiciones, and the Caldera plant in the port of Caldera, acquired by the American Smelting & Refining Co. from the Edwards interests. Notwithstanding that Chile is apparently well supplied with custom smelters, and that the price of copper would appear to be attractive, the high rate of exchange, the excessive cost of materials and ordinary commodities, combined with the low prices paid for ores, have combined to oblige practically all the small mines to shut down; and they are not a few. In such districts as Copiapo, Coquimbo, and La Higuera, the situation has become sufficiently acute to provoke a discussion in Congress regarding the advisability of establishing government owned and operated custom smelters. It is difficult to understand why plants operated by the Government would relieve the situation without having to operate at a loss, but the near approach of election time may have

some bearing on the fact that the measure is being patronized by the congressmen from the affected districts. Quién sabe?

Gold and silver mining are of minor importance, the small amount of gold produced coming almost entirely from placer workings in the southern provinces.

The coal-mining companies in the south of Chile are enjoying an era of prosperity, and until the recent determination of the allied governments to place the purchase of nitrate in the hands of one reliable agent, in order to eliminate competition in prices, the producers generally were wearing extensive smiles. At present the market is weak and uncertain, with few transactions, and very little demand. The outlook, consequently, is gloomy. A short time ago a paragraph in the MINING AND SCIENTIFIC PRESS announcing the Government's intention of organizing the purchase of nitrate, stated that there was no justification for the high price prevailing, but I am sure that the assertion was made without an intimate knowledge of local conditions in Chile. It is a well-known fact that the major portion of the cost of producing nitrate is the item of fuel, as all the raw material must not only be crushed, but boiled as well, in order to dissolve the sodium nitrate. In the last few years almost all the producers have adopted fuel-oil in preference to coal, and as the price of Californian residuum and Mexican crude (and crude it is, since most of it must be heated before it can be pumped) is now 50 shillings per ton as against 42 shillings at the outbreak of the War, this item alone is sufficient to influence the cost of the finished product materially. A further influential factor, which cannot be side-stepped, is the fluctuating monetary exchange. When nitrate commanded a much lower price than at present, a producer was able to buy from five to six Chilean pesos for an American dollar, while today the purchasing power of a dollar is about three and a half pesos. Unfortunately the rise in exchange was not accompanied by what should have been the logical drop in prices, nor has the price of labor been lowered. On the contrary, the increased cost of commodities has been accompanied by a demand for higher wages which has been generally met by the employers, and as the nitrate producer pays his labor in pesos his cost of production has increased enormously. I imagine, that 12-shilling nitrate in Chile must look to some people, in the United States like 23½c. copper to a Government price-fixing committee.

SUMMARIZING the case of the Virgilina copper deposits, on the line between Virginia and North Carolina, F. B. Laney, in a monograph just issued by the Virginia Geological Survey, says that the hope of the district is dependent upon consolidation of the various ownerships. A large and complicated plant is not warranted by the size of any of the mines as now held, and in order to secure economy large tonnages of ore must be treated. It would appear that flotation has given good results but that it must be supplemented by other methods to yield high recovery.

The Duties of a Shift-Boss

By JOSEPH P. HODGSON

The object of this address* is to assist the shift-boss. Having served in that capacity myself, and having some knowledge of the things expected of the shift-boss, I have no hesitancy in saying that I know his duties are many and important, and if he is a real shift-boss and has a proper conception of his work, he is, without doubt, one of the most valuable men in the employ of the company. If, however, he is only a driver of men, it is quite possible he may be a positive injury to both the company and the men. Of the former type (real shift-bosses) I know we have a goodly number. Of the drivers only, if we have any, and I know there are very few, I sincerely hope they may soon be real shifters in the truest sense of the word.

The shift-boss is the man who stands between the company and the men. He represents the company to the men and interprets its policy. Consequently, the duties of a shift-boss are varied and far-reaching, and go beyond the ordinary idea of 'getting out the rock.' In working large orebodies of uniform grade his principal duty is to look after the tonnage and, when necessary, to crowd the mine for a still greater tonnage. At a mine like the Copper Queen it is entirely different. Here the shift-boss has many other problems and often he must use his individual judgment. Of these considerations, the one of greatest importance is the work itself.

While the individual responsibility for the employment of men has been removed from the shoulders of the foremen and bosses by the substitution of a central employment-office under the direction of a man whose object is to secure the most intelligent and best-trained men available for the work, the opportunity and duty of the foremen and bosses to "fit the man to the job" are still of supreme importance. In fitting a man to the job the first question which presents itself is, what are the man's capabilities? For example, can he tell ore from waste? Is his temperament such that he unconsciously wants to make a 'big showing' and, consequently, fails to sort the ore as clean as possible? Is he physically strong enough to stand up to the job, or can his intelligence be used to better advantage in some other direction? As, for instance, a man physically able to make a splendid worker in a sulphide stope when there is no sorting to be done might be absolutely wasted in mixed ore requiring careful sorting. Of course, over half of the work requires no particular knowledge of ore on the part of the man, and this fact should not be lost sight of in judging a man's value for this part of our opera-

tions. In development work, a man trained in railroad tunneling, underground drifting and raising, or similar lines, will be better fitted for this field than one trained in 'chloriding.'

So far, we have considered only the question of selecting men already trained. As a matter of fact, in recent years, with the tremendous expansion of metal-mining operations in the West it is becoming increasingly evident that the supply of trained men is practically exhausted, and to meet this condition it is necessary not only to select men but to train them for the job; and it is here that the bosses have their largest opportunity for valuable service. Bosses themselves are selected as much for their knowledge of how to do the work and how to instruct others to do it as for their ability to handle men. These questions of the selection of the man for the job and his proper training are, in a way, only secondary to the real constructive work of the boss. A carpenter selects his materials, tools, and methods for the particular job, but first of all, he must have a plan to work to. Similarly, the boss must have his plan complete in every detail for his run, fitted into that of the division foreman, whose plan, in turn, is fitted into that of the general foreman, and so on, each portion, as it were, dovetailed into every other until the whole makes a complete self-contained scheme of management able to take its stand in the mining world—a finished structure, well designed and efficiently operated. As some one has aptly said "the authority to issue an order entails the duty of seeing that the order is carried out." Naturally, this involves, besides the knowledge of how to carry it out, careful planning, as otherwise the issuer of the order will not know whether it can be carried out or not. For example, a man may be sent into a drift to drill a round of holes and finds only part of the outfit. He spends a couple of hours rustling the rest of the outfit, fails to get in his round and is seriously reprimanded, or, perhaps, in extreme cases, discharged for something that was not his fault, but entirely due to the failure of the shift-boss to work out a comprehensive plan in advance of issuing orders.

In the second place, it is the duty of every boss to do justice to the mine itself. First of all in regard to the method of extracting the ore: Small bodies of ore may be easily overlooked that may be connected to larger ones that would mean hundreds of thousands of dollars to the company. Of course, there are so many prospects that it is impossible to follow out each so-called break or stringer of ore. Nevertheless, it is the duty of the shift-boss to try to recognize a good prospect and report it to his foreman, so that the combined judgment of both men

*Delivered before the mine-foremen and heads of departments of the Copper Queen branch of the Phelps Dodge Corporation at Bisbee, Arizona.

will be exercised. This is an important consideration when we think that the life of the mine is really at stake and that it may be lengthened or decreased according to good or poor mining—in other words, lack of conservation of the orebodies.

The third consideration is vested in the proper interpretation of the company's policy. In general, the policy of this company is well known. It is to pay good wages in order to have the men contented and at the same time to operate the mines on a good business basis, so as to reap the maximum amount of profit. The attitude of the shift-boss may turn the feeling of the men either for or against the company. In fact, the popularity of the company is really at stake between the bosses and the miners.

Fourth is the importance of handling men. Every shift-boss should make a study of his men. First in regard to their ability, so as to fit the right man in the right place; and, second, in regard to discipline, so as to get his goodwill and his interest in the work, and at the same time have all orders obeyed. At this time when wages and bonuses are higher than they have ever been in the history of the district, there is a natural feeling that superhuman efforts must be made to maintain costs at their former level. Obviously, if good work was being done before the increase of wages, costs could not be held down by simply attempting to increase the efforts on the part of the men. The policy of the company in paying these wages is not to obtain the privilege of driving the men any harder, but is to share with them the increasing prosperity of the industry. At the same time the situation does present an extremely favorable opportunity for the study and introduction of new methods for making the same amount of effort more effective. We all know the difficulties encountered in asking an old experienced miner to change his way of doing something, but with the added incentive of more money these changes can be made much more readily. It is useless to expect a man to judge of the company's feelings toward him except in the light of his treatment at the hands of his immediate superiors, and this responsibility of the shift-boss to represent the company to the men both wisely and well, is, after all, the most important duty to them both. It has been said that justice is man's most important mission on earth. Now, unless a boss thoroughly understands the interplay of the forces set in motion by his orders, he cannot hope to estimate their results justly and distribute praise and blame where they belong. In addition to this there can be no co-operation that is not founded on mutual respect, and blackguarding a man, while it may arouse fear and hate, can hardly be expected to arouse esteem and respect. Without the co-operation of his men a boss is as helpless as a new-born babe. In recognition of this fact, too much importance cannot be laid on upholding his authority and discipline over his men; that is to say, he should hold his men individually responsible for the orders issued to them and should be held personally responsible by his foreman for

the execution of all orders issued to him; the foremen, in turn, being held personally responsible for all orders issued to them. This system of responsibility, excepting in cases of extreme emergency, should be adhered to firmly.

In concluding these remarks, I hope that each of you will realize the responsibility that rests upon you. If you consider everything carefully when giving orders, so as to make it clear to your men just what should be done and see that they have the proper tools with which to do it, then you have the right to expect a reasonable day's work. Of course, you may not always be right and you will make mistakes like anyone else, but you must remember that you have been selected by your superiors on account of your ability to transmit and interpret their orders and that in every order you give, regardless of whether it is right or wrong, the company will be back of you and is upholding your judgment, giving you the benefit of the doubt until you should prove yourself unworthy of their confidence. The responsibility for good discipline and the goodwill of the men to yourself and the company rests entirely upon your shoulders. It is, therefore, of the greatest importance that you try to interpret the policy of the company correctly and to use your best judgment in matters of discipline, presenting orders and expecting a fair day's work, so that you will hold the respect and confidence of your men. I am convinced that the foremen and bosses of this or any other mining organization constitute the best asset of the company they are serving, provided they treat the men under their charge fairly, justly, and humanely. What can be a better asset to our company than a force of clean, satisfied, well-paid men, who have the fullest confidence in the organization under whom they are working, and who in case of either hard times, or in times of labor stress or strain, know of a certainty that the official representatives of the company are ready and willing to give to each workman a square deal.

CHILEAN NITRATE, the existence of which was first mentioned in 1809, is said to have been first exported in 1830. Only a few thousand tons per annum was exported for some years, but the amount gradually increased until, in 1879, at the time of the Chile-Peruvian war, when the exports amounted to about 300,000 tons. This nitrate was largely produced from the Province of Tarapacá, which, until then, had been Peruvian territory. By the terms of peace with Peru in 1884, this province, as well as Tacna, became Chilean territory. The Bolivian Province of Antofagasta was also acquired as a result of this war, and thus Chile, with the deposits in her own territory, acquired control of the whole supply of nitrate. At the present time, exports are approximately 3,000,000 metric tons per annum, having a value, at the point of embarkation, of about \$50 per ton, or a total of \$150,000,000. The nitrate industry, measured by its monetary value, is thus of great importance—Rogers and Van Wagenen, Bull. A. I. M. E.

High-Temperature Resistance Furnaces

By W. E. RUDER

*In 1911, Winne and Dantszen described two forms of resistance furnaces using ductile molybdenum or tungsten as resistors. Since the discovery, in the research laboratory of the General Electric Co., of methods for producing these metals in ductile form, their use as resistance elements has grown to such an extent that they are now almost indispensable. These furnaces are used for alloy research, annealing, heat-treating, and practically all of the thermal processes requiring temperatures above 900°C. Various types of furnaces have been developed to meet other needs of laboratory work. A

easing gas tight and to provide it with an inlet and outlet for the neutral or reducing gas. On account of its greater pliability in heavy sections, molybdenum is commonly used for the windings. Its melting point (about 2550°C.) allows for a sufficient range above the softening temperatures of available refractories to make it unnecessary to employ the higher-melting tungsten. This holds true when resistors are run at atmospheric pressures; if, however, it be desired to run at reduced pressure or in a vacuum, tungsten is used, because the high vapor-pressure of molybdenum renders it unsuitable,

FIG. 1. HIGH-TEMPERATURE RESISTANCE FURNACE

FIG. 2. VERTICAL TUBULAR FURNACE

tubular furnace, wound with a metallic resistor, is the simplest type to construct, and almost every laboratory has such furnaces. The only essential difference between a furnace wound with platinum or a base metal and one wound with tungsten or molybdenum is that the coils of the latter must be heated in a neutral or reducing atmosphere. It has long been the custom in the G. E. laboratory to build resistance furnaces with a metallic casing from which the tube could be easily removed for re-winding. The heat-insulating material, usually calcined magnesia, alumina, silica, or silex, depending upon the nature of the resistor, is used in powdered form so that it can be removed and replaced readily. In order to adapt this method to tungsten or molybdenum windings, it was necessary to make the

and because a much higher temperature is available. The resistance of tungsten at 25°C. is 5.0 microhms per centimetre cube, and its temperature coefficient of resistance is 0.0051 (0–170°C.). Molybdenum has a resistance of 4.3 microhms per centimetre cube at 25°C. with a temperature coefficient of 0.0050 (0–170°C.).

The horizontal type of furnace in greatest use is shown in Fig. 1. The alumina tube (1) is fitted into the cast-iron box (3) provided with a lid (2) which is bolted on over an asbestos gasket. The flanges (4) are screwed in so as to make a good contact with the ends of the tube (1). Hydrogen is piped into the case through inlets (15–20), and escapes through the alumina tube and the outlet (5). No. 9–13 show details of the current-terminals. With this furnace, temperatures up to 1750°C. are readily obtained, but if a higher temperature is attempted the alumina tube begins to sag badly. Furnaces have been successfully maintained at higher tem-

*Abstract: 'High-Temperature Resistance Furnaces with Ductile Molybdenum or Tungsten Resistors,' presented at New York meeting, A. I. M. E., February 1918.

peratures, but only with tubes of small diameter for the same thickness of wall. With one of these molybdenum-wound furnaces a temperature of 1700°C. may be attained in about 2 hours, but, for safety, about 3 hours is usually allowed.

It is often necessary to construct furnaces of larger size; these have been equally successful, but not for such extreme temperatures. For maintaining a temperature of 1750–1760°C., with a 36-in. aluminum tube, 3 in. diam. inside, wound with 128 turns of 0.05-in. molybdenum wire, four turns per inch, insulated with 4-in. alumina, this furnace required a total of 5920 watts or $5920 \div 301.6 = 19.6$ watts per square inch of inside heating-surface. Horizontal furnaces of this diameter do not last long at this high temperature, but if the temperature is kept below 1600°C., a long life is possible.

Another useful form is the vertical crucible furnace. This type has been built in many different sizes. The heating tube varies from $1\frac{3}{4}$ to 6 in. inside diameter. Fig. 2 shows the construction. The aluminum tube is $12\frac{1}{2}$ in. long by 3 in. inside diameter, with $\frac{3}{8}$ -in. walls; wound with 26 turns molybdenum wire, 0.067 in. diam., 3 turns per inch, and insulated with alumina, $3\frac{1}{4}$ in. thick. The total heating area is 84 sq. in., the current used being 31.2 watts per square inch at 1565°C.

A molybdenum resistance wire, after having run at a high temperature for some time, crystallizes so that it loses much of its original ductility and can seldom be unwound without breaking. If it is not too much caked with the fused alumina-packing, it can be loosened and the whole slipped off and put on another tube.

Influence of Brine on Reinforced Concrete

Reinforced concrete is by far the most popular structural material in use today. It is employed for the foundations of stamp-mills, often for the buildings enclosing them, and for treatment-vats contained therein, while the flume that conveys the water for power is frequently made of this material; but concrete, like everything else, has its limitations. The oldest reinforced concrete structures were built less than 20 years ago, and what the best of them will be like 50 years hence is a matter of pure conjecture. It is known, however, that there are some purposes for which reinforced concrete is wholly unsuited, and particularly is this the case where it is subjected to the action of salt and brines. Sea-water gradually causes the disintegration of cement; although many massive concrete structures have withstood the action of sea-water for many years, and are likely to stand for many years to come. Still, the disintegration is slowly going on, and is generally supposed to be caused, during setting, by the action of the magnesium sulphate of the sea-water on the lime and aluminates of the cement, with the formation of calcium sulpho-aluminate, which crystallizes with a number of molecules of water. Commercially, in fact, outside of the laboratory, it is practically impossible to make a concrete wholly

impervious to water, and when the water coming in contact with the concrete carries salts, such as sodium chloride, that have a corrosive action on iron, it conveys them to the reinforcing material, and the latter, instead of being a source of strength, then becomes a source of weakness, for, in corroding, the iron expands, first cracking and ultimately breaking away the surrounding concrete. H. J. M. Creighton* gives an account, illustrated by photographic reproductions, of a number of buildings of reinforced concrete that he has examined in different parts of the United States. In all of these buildings salt or brine was used to a considerable extent, for the curing of foods or for other purposes, and the solutions being spilled on the reinforced concrete floors invariably produced a markedly detrimental effect. In the early stages the under side of these floors developed cracks stained by iron oxides and chlorides. As the injury proceeds, these cracks, which follow the network of reinforcing material, enlarge, and ultimately wedge off portions of the concrete. In some of the worst cases cited the reinforcing material, which originally was $\frac{1}{2}$ in. diam. swelled to $\frac{1}{4}$ in. while the core of iron-wire inside was only $\frac{1}{25}$ in. diam. When concrete construction is carried out in winter in cold climates, salt is often added to the mixing-water to prevent freezing. Mr. Creighton examined a quantity of such work and found that, when subject to the influence of moisture, deterioration invariably resulted, but when kept dry no damage could be observed.

From his observations, Mr. Creighton draws the following conclusions: "1. All concrete which is not waterproofed in some way is somewhat porous to water and brine. 2. Brine readily softens the surface of concrete, and, therefore, more easily penetrates to the reinforcement, on which it exerts a disintegrating action that, owing to the attendant expansion, causes it to crack and split and, in some cases, to fall away from the reinforcement. 3. The more porous the concrete the more rapid the disintegration of the reinforcement through the action of brine. 4. Reinforced-concrete floors that come in contact with brine will gradually develop leaks. These will be followed by incrustations of discolored salts on the under side, when, later, iron-stained hair-cracks will develop, running parallel to the reinforcement. As the deterioration progresses, the cracks will widen and, owing to the great expansive force of the accumulating iron oxide, the concrete will be gradually pushed from the corroded reinforcement and ultimately fall."

From these observations it will be evident that where concrete comes in contact with water carrying salts in solution that corrode iron, reinforcement will ultimately be a source of weakness rather than strength. Thus, in flumes that are to carry some of the brackish waters of the West, reinforced concrete is likely to prove less permanent than plain concrete. Mr. Creighton's article raises the question whether it might not be more economical in the end to use some reinforcing material other than iron—monel metal, for instance.

*Journal of the Franklin Institute, November.

Metal-Corrosion in Float-Valves

By PAUL T. BRUHL

To decide on the material most suitable for the float of a float-valve regulating the flow of acid sludge, strips of galvanized iron, wrought iron, and copper were partly immersed in beakers containing the oil, and allowed to stand at the ordinary mill temperature. The following results were obtained:

CORROSION TESTS				Remarks
		Time of contact, hr.	Loss in weight per sq. in. per hr., gm.	
Galvanized iron	65	0.0000291	Corrosion fairly uniform, except at oil-air zone, which was stained black.
"	"	167	0.0000261	
"	"	407	0.0000239	
Wrought	"	43	0.0000440	Corrosion less uniform; brown and bluish-green stains on test-pieces.
"	"	145	0.0000212	
"	"	385	0.0000292	
Copper	48	0.0000517	Corrosion at oil-air zone relatively great. Immersed portion of test-piece darkened; strong local pitting.
"	151	0.0000273	
"	391	0.0000184	

The value 'per square inch per hour' was obtained by dividing the loss in weight in grammes by the number of test-hours, by the number of square inches of the test-piece immersed in the acid sludge. It is seen that the loss in weight is least in the case of copper, but as the copper is strongly corroded at the oil-air zone its usefulness for a float is impaired, and it cannot be regarded as satisfactory compared with galvanized iron, which is more uniformly if more rapidly attacked. In the case of the wrought iron an increase in the rate of corrosion is seen after about 150 hours; this increase coincided with the appearance of the stains, and may be attributed to secondary reactions. A metal corrodes in two stages; the first holding good when it is freshly immersed in the corroding liquid, when the velocity of attack indicates the true rate of corrosion; the second when the corrosion or oxidation products have been deposited or formed on the metal, when the rate of corrosion becomes a factor of secondary reactions. The conclusion arrived at, therefore, was that galvanized iron would prove most satisfactory for the purpose.

Movement of Gold and Silver Bullion

The movement of gold in 1917, while largely in favor of the United States, was by no means as decidedly so as in 1916, as a result of various credits arranged for the financing of purchases here by our Allies. Much the greater part of the year's inflow came, as in 1915 and 1916, for the account of Great Britain and our other European allies in the War, either direct by steamer or from the depository of the Bank of England at Ottawa, passing into this country by way of Ogdensburg, New

York. In the aggregate, Great Britain sent us 500 million dollars, or about 93% of the year's total influx, of which all but an insignificant amount came from or through Canada. Arrivals of gold from France were merely nominal, but from Australia they were 12 millions, South America 7 millions, and West Indies, Mexico, and other countries to the south, 19 millions. Collectively the inflow of the metal for the 12 months reached \$537,854,374, against \$685,990,234 in 1916, and \$451,954,590 in 1915. Shipments of gold were also very

extensive, reaching a total of \$371,883,884, or more than 1½ fold those of 1914, which, up to that time, had been the largest ever reported for any one year in the history of the country. The outflow consisted of about 104 million dollars to Spain, 45 millions to South America, 156 millions to Japan, 16 millions to the West Indies, 11 millions to Canada, and 40 millions to Europe, India, and the East. The net import-balance for the year, at \$165,970,490, compares with similar remainders of \$530,197,307 and \$420,528,672 respectively, in the two preceding years, and a net efflux of \$165,228,415 in 1914.

The imports of silver in 1917 were of about the normal amount, with Mexico the chief contributor, but the exports showed a heavy gain, partly, of course, due to the enhanced value of the metal, with Great Britain and British India the largest absorbers. The net exports of silver were \$30,790,044, against \$38,331,748 the previous year. Bringing together the various balances, we have the subjoined comparative summary for a series of years:

YEARLY TRADE BALANCE				
	1917	1916	1915	1914
Mdse. exp.	\$3,273,789,699	\$3,091,005,766	\$1,776,074,132	\$324,348,049
Silver exp.	30,790,044	38,331,748	19,114,930	25,643,873
Total	\$3,304,579,743	\$3,129,337,514	\$1,795,189,062	\$349,991,922
Gold imp.	165,970,490	530,197,307	420,528,672	165,228,415
Grand total	\$3,138,609,253	\$2,599,140,207	\$1,374,660,410	\$515,220,337

With all items included, the net export-balance for 1917, it will be observed, reaches the stupendous aggregate of \$3,138,609,253, or 539½ millions more than in 1916, and 1764 millions in excess of 1915. It must be noted in passing that our net gain in gold since July 1, 1914, a period of 42 months, reaches 1005 million dollars. —'Commercial and Financial Chronicle.'

Bank Credit and Bond Issues

There is something so plausible and insidious about the idea of financing the War by having the banks create new credit that the stern alternative of cutting down the use of credit for other purposes, and of curtailing all business but that which supports the War, has a poor chance of popular favor beside it. What is the objection to a pyramid of credit, based upon Government bonds, and consisting, first, of individual credit, second, of member-bank credit, and, finally, of reserve-bank credit, all backed by the taxing power and the power to issue money? What can be better than such a combination as this? Why not finance the War in this way?

The answer is that this pyramid of credit cannot add one day's work to the industrial resources of the country. The entire programme upon which the Government is proposing to spend about \$20,000,000,000 this year is all a matter of day's work. In times of peace the labor of the country is employed in private operations. The production consists in part of necessities for immediate consumption, in part of luxuries, and in part of additions to the productive equipment. Now comes the War, and the Government wants to take over a great portion of the working force, and also asks the people to turn into the Treasury money enough to pay it. The rational way of complying with this request would seem to be, first, to cut out the production of luxuries or non-essentials; second, to cut down the additions to permanent improvements and equipment, restricting them to such only as will aid in carrying on the War and the essential industries; third, to keep enough people employed upon necessities to support the country and the army, and to put all the others on war work; fourth, to turn into the Treasury, through taxes and loans, the money which was previously paid to these people now released from private service to war work. Since we are no longer expending the money in the old way we can let the Government have the use of it. The account balances. The country has simply diverted purchasing power from one class of work to another.

The other way of meeting the Government's appeal for help is to say, as considerably as possible, and with all possible assurance of patriotism, that we are sure that, if allowed to continue our industries and occupations as usual, we will be able to do a great deal more for the Government than we possibly can if we are interfered with; therefore, we offer to co-operate in getting up this pyramid of credit, and challenge the world to show wherein this credit is defective or insufficient. We, as individuals, will give our notes to our bankers, the latter will lend us the credit with which to buy Government bonds, and we will deposit the bonds with our notes as collateral security; the bankers can re-discount these notes at the Federal reserve banks, and thus recoup themselves for the advances they have made; and, finally, the Federal reserve banks, on the strength of the Government

bonds in their possession, and by virtue of the power to issue money, can furnish the currency to pay all bills.

The object of this elaborate scheme—this pyramid of credit—is to supply the Government with the means to go off and fight the War by itself, leaving us, the people, to go on with business as usual, undisturbed. The weakness in the scheme is that it does not provide the Government with army, navy, or equipment. These can be had only by taking men—labor—out of peace employments and placing them in the employ of the Government; but when this is done, they go off our private payrolls and upon the Government's payrolls, and if we will now pay into the Treasury what we formerly paid to them, or for the things they were making, there will be no need for a pyramid of credit.

There is a theory that this war task can be handled somehow by increased energy and out of resources heretofore in reserve; but the demands of the Government are very elastic; they amount to all it can get. The more men we can send to France the better, the more cannon we can put on the line the better, the more ships and aeroplanes and supplies we can send, the better. And finally the more people we can keep on the farms and send back to the farms, the better.—National City Bank Circular, February 1918.

ALUMINUM production has tripled in the last five years. The world output for 1912, and the present capacity of the different countries, is given as follows:

	1912, tons	Present capacity, tons
United States and Canada	26,300	75,000
France	13,000	20,000
Switzerland	10,000	20,000
United Kingdom	7,500	12,000
Norway	1,500	16,000
Italy	800	7,000
Total	59,000	150,000

The aluminum industry is busily engaged in preparation for the time after the War, as it is supposed that a rich field will then be opened up for the use of various alloys of aluminum. It is thought that aluminum will, in many instances, be used as a substitute for copper and tin plate.

GOLD PLACERS were recently reported to have been found at Nieble and Villarrasa, in the Province of Huelva, Spain. In ancient times important quantities of gold were obtained from the valley of the Rio Tinto by the Phoenicians, representing concentrations from the eroding outcrops of the copper deposits. It is interesting to note that those venturesome pioneers should have overlooked any sources of the precious metal, and that the deposits should have remained unknown until this late day, especially in a region that has been carefully studied by so many able engineers. The new discoveries are in gravel beds in the Sapo Arroyo, which drains into the Rio Tinto.

A MOUNTAIN OF OIL-SHALE IN EASTERN COLORADO

Mining in Colorado

By ARTHUR J. HOSKIN

An institution intimately linked with the mining and metallurgical successes of this State is the Colorado Scientific Society. For many years this was the premier technical organization of Colorado and its membership roll contains the names of practically every man who had a hand in upbuilding the mining industry of the State. Most of the faithful workers of the old régime have passed and, during recent years, interest in the society has waned somewhat, there being too few members able to devote the time and energy necessary in keeping such a society properly alive. Feeling that a change of some sort might be beneficial, the executive committee has decided that, in place of the customary monthly meetings, there will hereafter be held but four meetings during a year, two in the spring and two in the fall. Each meeting will be preceded by a dinner. Addresses will be made by persons of eminence and dates of meetings will be set to accommodate the engagements of the speakers. The committee plans also to return to a former practice of publishing all addresses in bulletin form. This year's officers are: Richard B. Moore, president; Lewis B. Skinner, first vice-president; Marmaduke B. Holt, second vice-president; Harry J. Wolf, secretary; John W. Richards, treasurer.

Another organization holding the interest of Colorado mining, chemical, and metallurgical men is the Teknik Club, which, a few years ago, succeeded the Western Association of Technical Chemists and Metallurgists. Its meetings are held monthly at the Shirley hotel, Denver, taking the form of dinners followed by papers from members. As a rule—and as originally intended—the papers and discussions are upon strictly technical topics selected by the speakers. Recently, however, the club has enjoyed innovations when members have chosen as their subjects such topics as 'The Oriental Problem,' handled by Mr. Davis, and 'The New Psychology,' by Mr. McFarlane. At the February meeting, Mr. Roach, of the Great Western Sugar Co., spoke in detail upon 'Beet Sugar Manufacture.'

Professional men insist that Colorado must become an 'oil' State. When we had about concluded that the State's possibilities had been exhausted in the oilfields of Florence and Boulder, there came the excitement in the neighboring States of Wyoming and Kansas, leading many Coloradans to wonder why we could not push our State into the 'game,' as it is called. But geologists able to diagnose conditions gave us little encouragement for drilling in eastern Colorado, the region that is geo-

graphically between the neighboring productive States and geologically like them. Prof. Victor Ziegler of the Colorado School of Mines is delivering a series of popular lectures on petroleum in the legislative chamber of the Capitol. We are being awakened to the potentialities of great beds of oil-shale in the western part of the State. A new industry for America seems about to start in the excavation and retorting of this shale. Numerous companies have secured holdings and are planning to erect mining and distillation plants as soon as the weather will permit. Dr. David T. Day of the U. S. Bureau of Mines spent a few days in Denver recently and made two addresses on our oil-shale. His first lecture, delivered at the Capitol, elicited so much discussion and so many inquiries that a questionnaire was hastily planned and held the following day in the Chamber of Commerce. At this unique meeting Dr. Day frankly answered to the best of his ability every question asked, irrespective of the effect his statements might have on individuals, promoters, companies, or inventors. In his own words, he "clipped a good deal out of many prospectuses," and the meeting had a most salutary effect upon this budding industry. At this writing, oil-shale enthusiasts are uneasy about threatened legislation at Washington, but the cool-headed ones maintain that the Government will not do anything to disturb locators *ex post facto*. Hastily called sessions of shale-men were held at DeBeque and Denver and delegates have gone to Washington to lobby for the Walsh-Pittman bill, which is satisfactory to Western oil-men, but is meeting opposition from the ultra-conservative forces.

An interesting mining suit has been concluded in Denver. William B. Milliken, mining engineer, was defendant in a suit for \$190,000 brought by Henry E. Frederickson, who charged fraud in connection with the sale of the Linda Ventura mine in Nicaragua. The trial occupied several days and brought out many charges and counter-charges. One point insisted upon by the plaintiff was that he lost his health by a trip to the property. Milliken maintained that he had forewarned Frederickson against the malarial conditions in Nicaragua and that the plaintiff, instead of providing himself with proper medicines, had relied upon his faith in a certain religious cult to resist disease. The suit was won by Milliken.

A bed of sulphur ore $7\frac{1}{2}$ ft. thick, close to the surface of the ground, was located near Delta this winter. A short time ago, a well, being drilled near Delta for oil, turned into a geyser spouting sulphurous hot water.

The Primos Chemical Co. has its 250-ton mill at Camp Urad in Clear Creek county nearly completed. Mining men have been amused at an item in the daily press to the effect that a prominent sugar company is considering the erection of a sugar plant at Idaho Springs. Is this mountainous county to turn from mining to agriculture? The proposal is on a par with the ideas of the people of Leadville, a year ago, that they could secure a Government aviation school.

The Cresson mine has been again used to furnish spectacular news. This time the statement is made that

new development on the 10th level has added upward of a half million dollars worth of \$150 ore.

The Degge-Clark Tungsten Mining, Milling & Refining Co. has been reorganized as the Caribou Metals Co. It will hereafter own and operate not only the proved tungsten mines and mill in the Nederland district, but a well-known group of silver mines at Caribou.

At the annual meeting of the Golden Cycle Mining & Reduction Co. the following directors were elected: A. E. Carlton, H. McGarry, Richard Roelofs, L. G. Carlton, E. P. Shove, Spencer Penrose, Irving T. Snyder.

Some persons entertained a notion that the annual meeting of the Vindicator Consolidated Gold Mining Co. would be wildly exciting because, a year ago, disgruntled stockholders started a little tempest and it was presumed that they might come to this year's meeting sufficiently fortified to wield influence in the election of directors. However, it seems that diplomacy was utilized in healing the wounds and the old directors were re-elected without a dissenting vote. They are Guilford S. Wood, A. E. Carlton, George A. Stahl, Adolph F. Zang, Irving T. Snyder, Philip A. Zang, and Charles Siegel Jr. The announcement was made that the flotation-mill is a success financially and will soon be treating 1000 tons daily.

POTASH and soda feldspars are mined near Kingston, Ontario, the former containing 10 to 12% of potash and the latter as high as 10% of soda. Prevailing prices are from \$4 to \$4.50 per net ton f.o.b. Canadian shipping point. The best time to purchase feldspar is in the winter season, as shorter hauls can be made then over frozen streams and marshes. There are two large grinding plants near Rochester, New York, importing feldspar from the Kingston district. The crude stone pays no duty on entering the United States while the ground spar pays a duty of 20%, therefore the grinding plants are in the United States. The value of feldspar exported from the Kingston district to the United States in 1917 amounted to more than \$100,000; this year's contracts will exceed \$300,000.

THE 'KIMURA TERM' is the title given by geo-physicists to a variation in latitude, discovered several years ago by a Japanese of that name, since confirmed by scientific men throughout the world. It consists in an effect similar to that which would result from an annual wandering of the centre of gravity of the earth to and fro along its axis, equivalent to a variation in the position of the centre of gravity of about three metres.

LEUCITE crystallizes in the lavas from Vesuvius, and the amount present is so large that the total potash content of these lavas often exceeds 7.5%. The formula is $\text{KAl}(\text{SiO}_3)_2$, representing 21.5% of K_2O . Leucite is characteristic of many modern lavas, and it forms mountain masses at the Leucite hills. Green River basin, Wyoming, which are as rich in potash as the Vesuvian lavas.

REVIEW OF MINING

NEW YORK

GENERAL SITUATION BETTER.—STOCK MARKET.—DETINNING PROGRESS.—MINING METHODS IN NEW YORK CITY.—A. I. M. E. MEETING.—COAL USED IN LIGHTING CITIES.

Warmer weather has improved the general situation, and optimism prevailed when 'workless Mondays' were officially discontinued. Effect of the coal shortage is still being felt, especially at Newark, where many factories were shut-down during the past week and a great number of men were idle. Discontinuance of the fuel order is generally considered due to the fact that its enforcement was found impracticable, rather than that the results desired had been achieved. A salutary effect is already seen. Preventive measures against future disorganization are now well under way. New York City and New Jersey are to be connected by a tunnel for vehicular traffic. This will minimize the danger of a coal famine due to difficulties in water transport during severe weather. An ice-controller has been appointed with authority to cut up to 2,000,000 tons of extra ice from the Hudson and Mohawk rivers—a provision that will eliminate the fear of an ice famine in the summer and at the same time will save an immense amount of ammonia for war purposes.

Securities showed average net gains for the week. Even Liberty Bonds, after reaching a new low level, rallied and indicated a firmness in marked contrast to previous sagging tendencies. Peace and War news has been so intermingled that a neutralization of opinion has resulted; and market appreciations cannot well be ascribed to any well-grounded optimism. New import and export restrictions are not expected to be enforced in so drastic a manner that foreign trade will be crippled, or even seriously hampered. Experience with the fuel order has showed that exemption claims are successful in a great many instances, even when presented from unexpected quarters.

A new company, to be known as the Metal & Thermit Corporation, will result from the amalgamation of the Goldschmidt Detinning Co. and the Goldschmidt Thermit Co. The re-organized corporation will have a capital of \$3,250,000, and will control the operation of the plant at Jersey City for thermit products, and other plants at Pittsburgh, San Francisco, and Toronto. Perhaps the most interesting feature of its operations is in connection with the detinning works at Chrome, New Jersey, and East Chicago, which handle over 100,000 tons yearly of tin scrap and chippings and produce therefrom about 2000 tons of tin. Two processes are in use: One, in which chlorine, manufactured at the company's Wyandotte plant in Michigan, is introduced under pressure into containers packed with the scrap. Destruction of the iron is avoided by the entire exclusion of moisture, and the prevention of rise in temperature. The product is an anhydrous tetrachloride of tin. In the alternative process, a mixture of tin chippings is boiled with sodium alkali and saltpetre, by which stannate of soda is formed. Oxide of tin is ultimately precipitated by dissolving the crystals in water and by treating the solution with carbonate of soda. The oxide product may be smelted to produce a high grade of metallic tin, or may be used as a pigment in enamel work.

The complicated ramification of underground railroads connecting lower Manhattan (the island on which New York stands) with Brooklyn and extending to other suburbs, is making steady progress toward completion. The extent of the work is such that it is difficult to generalize successfully without involving fundamental details, and these are of so varied a character that space forbids. Several features, however, are worth mentioning. The dual subway system calls for two 4-track trunk-line subways to connect lower Manhattan with Brooklyn and four tunnels where necessary underneath the East river. The cost of this section was estimated at \$17,000,000, and this included five miles of shield-tunneling work. The Whitehall-Montague Street tunnel was holed through late in June last, after a record of 95 ft. 4 in. had been made in 6 days. The Brooklyn approaches are in some cases almost finished, and the work presented many interesting problems for the engineers. In one place, and for over a mile, the tunnels are lined with cast-iron and subsequently packed with sand and gravel delivered by compressed air. The ground through which the tunnels have been driven in Brooklyn is, for the most part, very loose, consisting mainly of sand, gravel, and boulders. Little trouble has been experienced from ground-water, although excavations were carried out in most instances below normal high-water mark. This was attributed to the fact that the locality is well drained by wells. In one instance a low water-pressure was encountered, and compressed air was used to keep the concrete in place until set, the blow-holes formed being subsequently plugged with a rich cement mixture. A feature of the work was the necessity for underpinning existing structures so that no surface settlement would take place as the work proceeded. At one part of Fulton street, Brooklyn, there will be four separate levels of subway trains and one elevated railroad structure; and it was necessary to carry out the tunneling directly under two existing subway tunnels and the elevated railroad structure, all carrying frequent trains, heavy street-car traffic, and lofty buildings. All the supports of the elevated railroad were underpinned in front and behind the shields as progress was made. As some of the buildings were 11 stories high, problems of tunneling through a loose soil underneath were fully appreciated in advance, and it was considered necessary in some cases to carry supporting walls to sub-grade. In other cases where the load was less, walls were supported by screw-jacks. Greater part of the work is carried out by shields that are pushed forward and form the support for the concrete which is allowed to set as the material in the space beneath is being excavated. Concrete is delivered through long pipes to the face, being forced through these by compressed air from a sort of monteju or cylinder. These pipes are quickly worn through, and this is a serious but apparently unavoidable factor of expense. The shield may weigh as much as 60 tons for large tunnel work, and in this case is pushed forward by means of 14 or more 110-ton hydraulic jacks operating with a pressure of 5000 lb. per sq. in. In certain parts, timbering methods have been adopted, but the work is slow and cumbersome compared with shield-tunneling, and calls for much lumber. Some of this is lost, as it cannot be recovered after the concrete is set. Phraseology of subway timbering is strange to the miner, who finds difficulty in understanding the origin of such terms as 'needles'

and 'whales'. Subway labor is recruited mainly from the foreign element, and men with a knowledge of timbering are in demand.

The 116th meeting of the American Institute of Mining Engineers opened here on February 18, when about 150 members and guests registered for the convention. The morning was taken up with sessions on coal and non-ferrous metallurgy, and consideration of six interesting papers. Vice-president Ludlow of the Lehigh Coal & Navigation Co. made some pertinent statements as to the coal situation. Anthracite production, he averred, has reached maximum production, and the possibility of discovering further deposits in the United States was remote. George S. Rice, of the U. S. Bureau of Mines, contended that a proportion of the recent trouble was due to individual apathy on the part of some of the miners, and that the high rate of wages now being paid tended to encourage frequent absences from work, and for no other reason. A visit to subway workings in Manhattan and Brooklyn was arranged for the afternoon, and the ladies were the guests of W. A. Clark and H. C. Frick at their Fifth Avenue residences.

Interesting figures dealing with artificial illumination were given by P. S. Millar at a meeting of the Illuminating Engineering Society of New York during the week. The speaker contended that artificial standards of illumination were too low before the War, and that much more efficient output could be obtained in certain industries by increasing artificial lighting. With regard to the question of the economy of coal by decreased lighting Mr. Millar pointed out that any practicable reduction would only effect an inappreciable saving of coal. The total amount of coal used in this country for lighting purposes was given as 12,000,000 tons per annum.

CRIPPLE CREEK, COLORADO

VINDICATOR CONSOLIDATED RESERVES.—SALE OF ORE-DUMPS.—IRONCLAD HILL MINES.—LEASED MINES' ACTIVITIES.

Annual meeting of the Vindicator Consolidated Gold Mining Co., held at Denver on February 14, resulted in re-election of former directors and officers, as follows: president, G. S. Wood; vice-president and general manager, Irving T. Snyder; treasurer, Adolph F. Zang; and secretary, George A. Stahl; who with A. E. Carlton, Philip A. Zang, and Charles Siegel Jr., complete the board. Report of Louis S. Noble, consulting engineer, stated that company ore production in 1917 was derived almost entirely from previously opened reserves, which have been depleted accordingly. Measurable ore blocked out amounts to 255,000 tons, 114,370 tons of which is broken and 141,210 tons is in place. In addition, there is a large area of caved stopes in the upper portion of the Golden Cycle shaft, from which a substantial tonnage can be drawn which should yield a good profit by the present washing and milling system. About 100 tons daily has been drawn recently from this source, with satisfactory results; and although definite measurement cannot be made, it is certain that a considerable rate of production can be maintained for a long time.

Dumps on the Stratton estate have been sold outright for immediate removal, and most of the ore will be treated at the Golden Cycle and Portland mills. These dumps are the Abe Lincoln, Poverty gulch; Keener tunnel on Globe hill; Half Moon and Geneva, Gold hill; Temomj, Gold hill; and Hidden Treasure, Lottie, Pikes Peak, and Garfield Grouse, on Bull hill. It is understood that the Stratton estate is to receive 75c. per ton for all rock moved. Henry Von Phul, former sheriff of Teller county, has commenced moving the Keener Tunnel dump to the Independence mill of the Portland company.

Edwin Gaylord, lessee at the Forest Queen on Ironclad hill, has commenced shipping from new orebodies opened on the 650 and 750-ft. levels. Returns from a car of screenings from

the deeper levels were settled for by the Golden Cycle company at over 3 oz. gold per ton.

Production started on February 23 from the Pride of Cripple Creek, another Ironclad hill property, operated by Cox, Beebe & Co., lessees. Ore mined at the 600-ft. level is estimated to carry 2 oz. gold per ton.

Track is being laid into the Index mine on Gold hill, and with the loading-switch in readiness for cars, the El Paso Extension Corporation will commence shipping. Three sets of lessees are mining ore on No. 2, 3, and 4 levels, and the company is mining better than 2-oz. ore from the bottom of the winze sunk 150 ft. from the bottom, or 900-ft. level. The property owned by the Index Consolidated Mining Co. is under bond to the present operating company, of which A. J. Campbell is superintendent.

Casson and Fink, of Victor and Canon City, have opened a new and strong body of milling ore at a depth of 100 ft. on Block 3 of the Ajax, on Battle mountain. The trial shipment sent out this week is estimated at \$30 per ton.

The Victor Gold Mining Co., operating the Prince Albert group on Beacon hill, under lease and bond to purchase, shipped 1-oz. ore last week.

SUTTER CREEK, CALIFORNIA

FREMONT SHAFT-SINKING.—SALE OF HARDENBURG MINE.—SOUTH EUREKA.

Two months work completed sinking the Fremont shaft 200 ft. to the 2950-ft. level, and station cutting is now under way. This is considered excellent progress. Several miles of driving and cross-cutting have been done from the Fremont and Gover shafts during operation of the combined properties, the Gover shaft having a depth of 1500 ft. and being connected with that of the Fremont. Oil is used for fuel for the steam hoists at both shafts, and the 40-stamp mill is operating steadily. The vein from which the property has been successfully worked for many years is about 6 ft. wide. About 200 men are employed.

A trustee's sale of the Hardenberg mine, south of Jackson, took place at the court-house this week. John Dohmann purchased the property for \$10,000, but it is understood about a quarter of this amount will be refunded to cover the title to mill-site, the mill having been constructed on ground other than that owned by the company. This means that the proceeds of the sale will net the creditors only about 18% of their claims. The Hardenberg Mining Co. of San Francisco purchased the property about five years ago and spent considerable money on development, including shaft-sinking. While indications seemed good for pay ore, the equipment proved inadequate for handling the water and extracting the ore at a profit, so operations discontinued. A company headed by W. J. Loring worked it under option for a short time since, but the purchase was not consummated. Creditors of the Hardenberg company assigned their claim for material and supplies to C. L. Culbert, as trustee, and the sale was made for their benefit.

Prospects appear brighter for the South Eureka mine, as a number of the men who were recently laid-off have resumed work in the shaft, and preparations for sinking are now under way. It is stated that this change of plan is due to the faith of the management in the property and the fact that conditions in the adjoining Central Eureka mine in depth are so good. H. Malloch is general manager, and W. H. Schmal, superintendent, of this property, which employs about 300 men when the entire plant, including the Oneida property, is in operation.

WASHINGTON.—The Sierra Asbestos Co. has been authorized by the State Corporation Commission to issue shares, etc., to purchase and operate unpatented mining claims in this district.

PLATTEVILLE, WISCONSIN

EFFECT OF PRICE-FIXING ON ZINC ORE.—LEAD ORE AND SULPHURIC ACID.

Government price of 12c. per pound on high-grade spelter evidently had an effect on the ore situation in this region, as demand for such metal stimulated demand for high-grade ore.

The Mineral Point Zinc Co., with smelters at DePue, Illinois, also mines and concentrators in the Wisconsin field, produces high-grade metal, but recent unfavorable conditions curtailed the output.

While the Government price for high-grade metal helps some, an official of the American Zinc & Lead Smelting Co. states that no demand has been set up for prime Western, and there is now about 60,000 tons of this grade in stock. There is nothing, therefore, in the metal situation to warrant higher prices for zinc ore, but the situation locally has benefited zinc refiners, who were given advances of \$2.50 per ton on top grades of blende at \$62.50 per ton base, with an increase of \$5 per ton on second and medium grades. This situation is likely to prevail for some time at least, and ore production is being encouraged, especially with the larger operating groups affiliated with the zinc-ore refineries. The demand for the lower-grade ores has not been improved through these developments, and much concentrate is in stock at nearly all points in the field.

Lead-ore producers are involved in a complex situation, not readily understood by the layman. Large sales of ore have not been made for five months, during which time production has been above average. Offerings of \$85 per ton have been submitted, which gives a fair profit to producers, most of whom recover lead as a by-product through wet concentration of zinc ore; but sellers show no disposition to part with their product, and it remains to be seen whether they have exercised prudence in holding so long. Buying representatives are restricted in this field to practically one smelter—the Federal Lead Co. The New Jersey Zinc Co. has recently been in the field for lead ore, but succeeds only so far in obtaining the product of its own mines.

Firm offerings on lead ore give prospectors encouragement to re-open many old workings. In the Galena district at West Diggings several small companies have opened ore in new ground, especially on the Spillane farm. At a depth of 90 ft. three prospectors are mining 10 tons of 85% ore daily.

Demand for sulphuric acid has been strengthened by Government investigation of available supplies, and prices for pyrite have shown improvement for the first time in two years, open market sellers taking advantage with increased deliveries. Car shortage has retarded deliveries of February, and a large reserve is on hand, which owners are more than anxious to dispose of, as there is little pyrite coming direct from mines, and the fines held at separating-plants are felt to be an encumbrance on current production. Mineral Point Zinc Co. ships one 25-ton tank-car nearly every day. Most of this is delivered to the U. S. Steel Corporation, Pittsburgh. Large quantities of low-grade Western blende and high-grade Mexican carbonate ores are received at the zinc-oxide works of the company at Mineral Point, where the plant is running day and night.

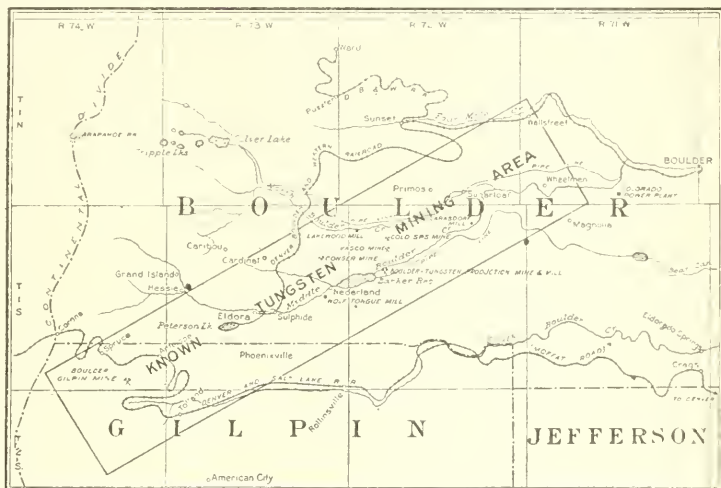

Shipments of zinc oxide in car lots have been given increased impetus recently, and a large force of coopers and bag-makers is now employed. Thousands of tons of coal-screenings are used in mixing the charges for the two blocks of double 10 furnaces, and during the coal shortage no shut-down was necessary on account of foresight of the management. The labor situation at Mineral Point Zinc Co.'s plants has been good all winter, mainly through employment of foreigners, many of whom are Italians.

NEDERLAND, COLORADO

MINES IN THE CARIBOU DISTRICT.

Mining outlook for Boulder county this coming season is good.

Caribou district will be the scene of a boom this spring. During winter high-grade silver-lead ore has been shipped in carload lots. Deep snow and lack of labor and transportation

MINING DISTRICTS OF BOULDER COUNTY, COLORADO

facilities have retarded prospecting and mining. High prices for silver resulted in re-opening old mines, and every lease was in demand. A fine development in the Conger Chief added impetus to operations.

Potosi mine of Davis Ingram has shipped four carloads of rich silver ore, and he hopes to send a car daily when conditions permit.

Johnson and Johnson, above the Potosi, are doing likewise. Comstock mine of Hankins & Co. is shipping three carloads per week of 1100 and 1600-oz. silver ore.

Snow—10 ft.—is hindering work at the Conger Extension of Russell and McSherry.

The Croesus claims in Hicks gulch, between Cardinal and Caribou, were recently located by Judge T. H. Thomas of Nederland.

A. B. Clarkson of St. Louis will do extensive work this year on claims adjoining the St. Louis and Boulder County Mines' tunnel.

Wolf-Tongue lessees are officially reported as doing well at tungsten mining, especially Nels. G. Olsen, who is working on a large deposit in the Cross mine, at Cold Springs. Company's concentrating mill is operating to capacity.

Conditions at Cottonwood were never better.

Nederland is also busy, and Beaver Creek.

Huron mine at Eldora is yielding high-grade gold ore, which is being held until the mill is completed.

TONOPAH, NEVADA

SUMMARY OF PROGRESS IN THE IMPORTANT MINES.

The Tonopah Mining Co. in January treated 15,500 tons of ore giving a net profit of \$56,340. Metal production was 1606 oz. gold and 146,477 oz. silver. At the Silver Top, 17 ft. of development has been done, 22 ft. at the Mizpah, and 52 ft. at the Sandgrass. On the 500-ft. level of the Mizpah shaft a raise has been started to prospect an undeveloped block of ground. On the 1300-ft. level of the Sandgrass the north cross-cut on the west drift made good progress without any change. Production last week was 3200 tons.

At the Victor shaft of the Tonopah Extension Mining Co. 156 ft. of work was done and 60 ft. at No. 2 shaft. At the latter, raise No. 641 on the 600-ft. level, made a connection with the level above. On the 1350-ft. level raise No. 572 advanced 11 ft. on a 4-ft. face of ore. At the Victor, on the 1440-ft. level, east drift No. 604 shows a 5-ft. face of ore. The intermediate east drift from winze No. 1501 on the 1540-ft. on the Murray vein advanced 24 ft. in ore. A raise will be started from the 1680-ft. level to make a connection with the intermediate drift. On the 1680-ft. level, work has been suspended on the O. K. and Victor veins until a connection by the west cross-cut from the Merger vein is made with the Cash Boy. Stopping has been started on the Merger vein showing 6 to 8 ft. of ore. The south cross-cut advanced 58 ft. toward the downward extension of the Murray vein. Production last week was 2380 tons.

The Tonopah Belmont Development Co. treated 10,357 tons of ore in January giving a profit of \$60,138. Metal production was 1270 oz. gold and 124,291 oz. silver. On the 800-ft. level east drift No. 8019 on the Occidental vein cut a fault, and a south-east cross-cut has been started to pick up the faulted segment. South cross-cut No. 8006 is being driven to cut the extension of the South vein on this level. Raise No. 20 on the South vein shows a 5-ft. face of good ore. On the 1000-ft. level east drift No. 1087 on the Favorite vein shows a decrease in the width of the vein, which is low-grade ore. On the 1100-ft. level east drift No. 1161 cut a branch of the Mizpah Fault vein showing medium-grade ore. On the 1400-ft. level north of the cross-cut No. 9 is following a small branch of the Shaft vein, which is a good grade of ore. Last week's production was 2256 tons.

At the Ohio shaft of the West End Consolidated Mining Co. intermediate No. 528 is being driven for a connection with raise No. 513 for mining purposes. Winze No. 534 made good progress in ore and drift No. 539 continues in low-grade ore. On the 555-ft. level No. 7 raise reached the hanging wall of the vein, exposing good ore. No. 3 and 5 cross-cuts are being extended, and new raises to the vein will be started at intervals. Cross-cut No. 601 is in the foot-wall of the vein, and is being driven for a connection with winze No. 534. When this is made, regular development will be started on this level. At the West End shaft, west cross-cut No. 809 is making slow progress in low-grade ore. The output last week was 1118 tons.

At the Halifax Tonopah cross-cut No. 1018 is making good progress, and drift No. 1019 continues on a stringer of high-grade ore. A new cross-cut has been started on the 1100-ft. level to cut the downward extension of the high-grade stringer. On the 1200-ft. level cross-cut No. 1256 has been discontinued, and cross-cut No. 1258 started.

The Jim Butler Tonopah Mining Co. in January treated 1893 tons of ore, giving a profit of \$3010. This is much lower than usual, due to repairs. At the Desert Queen shaft west drift No. 5 on the intermediate level between the 500 and 600-ft. levels shows a 4-ft. face of ore on the South vein. At the Wandering Boy shaft raise No. 376 on the Wandering Boy vein shows a 4-ft. face of medium-grade ore. On the 6th level east drift No. 630 is making good progress on the Wandering

Boy vein on low-grade ore. The output last week was 433 tons.

Cash Boy has advanced the west drift on the 1600-ft. level 40 ft. The face is in high-grade ore, and the width of the vein averages about 5 ft. Production last week was 55 tons, shipped to the Western Ore Purchasing Company.

The north cross-cut on the 700-ft. level of the MacNamara mine is making good progress. A raise has been started from the 600-ft. level to prospect the rhyolite-trachyte contact. The output last week was 538 tons.

The Montana produced nothing and miscellaneous 66 tons, making the week's production at Tonopah 10,137 tons having a gross value of \$172,329.

TORONTO, ONTARIO

LABOR.—HOLLINGER IN 1917.—DOME DEVELOPMENT.—ANKERITE, NORTH THOMPSON, AND ELLIOT-KIRKLAND.—TEMISKAMING AFFAIRS.—GOWGANDA FIELD.

The labor situation at Porcupine is better and prospects of increased production during the coming season are decidedly hopeful. Annual report of the Hollinger Consolidated is most encouraging. The total income for 1917 was \$4,271,260, with a gross operating profit of \$2,009,549. After deductions for depreciation, taxes, and donations, there remained a net profit of \$1,720,314. The deficit of \$269,590 was wiped out. Plant expenditure amounted to \$673,237, and \$131,224 was charged to capital development. The surplus on hand was \$712,724. The most significant feature shown is the notable increase in ore-reserves. Although over 508,000 tons of ore was extracted, reserve value has increased from \$34,185,535 to \$40,231,435. The new ore has been nearly all developed above the 800-ft. level, the ground below that depth being unexplored and of great speculative value. The average value of reserves is estimated at \$8.95, as against \$8.68 per ton a year ago.

Operations at the Dome Mines are confined to deepening the main shaft and exploration, but the ore extraction will be resumed as soon as sufficient labor can be engaged.

At the Ankerite the downward extension of the orebody has been found on the 200-ft. level. The shaft is being sunk to 500 ft. where it is proposed to open extensively, to be carried into the Maidens McDonald adjoining, which is also owned by the Coniagas.

Grade of ore milled by the Vipond-North Thompson shows improvement, averaging \$10 per ton.—Development work on the Thompson-Krist adjoining is to be carried on from the 400-ft. level of the Vipond.

Shaft at the Elliot-Kirkland is being sunk 500 ft. The vein, which was narrow at 100 ft., has widened at 300 ft. to 11 ft. of good grade.

At the Kirkland-Porphry No. 1 shaft is down 300 ft., where the vein is 5 ft. wide, showing higher gold content.

The serious disagreement among the Temiskaming shareholders developed in the course of a hot campaign waged by the interests represented by Max Morgenstern of New York, against the management, was brought to a close at the annual meeting on February 5, when the old directors were ousted and a new board elected. J. P. Bickell, of Toronto, was chosen president, and W. J. Sheppard, of Wabashene, Ontario, vice-president. The new president made it clear that he did not in any way represent the Morgenstern faction, and the election was made unanimous. The board fixed the salary of the president at \$7500 and that of the vice-president at \$1000.

At the Beaver, a winze being sunk from 700 ft. to the 800-ft. has cut high-grade ore.

The Trethewey is actively pushing work on the Castle property in the Gowganda district. Large buildings are being erected, and preparations are being made to bring in machinery, which must be hauled 25 miles from the end of the railway.

THE MINING SUMMARY

ARIZONA

BISDEE.—Shattuck-Arizona Copper Co. reports that for 1917 net profits totaled \$1,477,500, against \$3,074,013 in 1916, and \$1,174,027 in 1915. Dividends last year amounted to \$612,000, compared with \$1,662,500, and \$875,000. Surplus at end of 1917 was \$2,375,397, an increase of \$100,000.

GLOBE.—Iron Cap company announces that the orebody recently opened on 10th level is 50 to 55 ft. wide. Ore is estimated to average 6% copper, but in streaks is as high as 35%. Company is now driving both east and west on the vein. Last month shipments totaled 138 carloads, a new record. Sinking has been resumed on the Williams shaft, 20 ft. having been sunk from the 1100-ft. level.

Owing to a blow-out in an air-pipe to a hoist at the Williams shaft of Iron Cap mine, four men could not be taken out, and were killed by a charge that had just been lighted.

Profitable ore has been opened on the 1500-ft. level of the Arizona Commercial.

JEROME.—Jerome Verde Copper Co.'s Columbia shaft was down 1100 ft. at end of 1917, and 1859 ft. of drifts and 1342 ft. of diamond-drilling done. From the north-west workings—900 ft. deep—1610 tons of 8.55% ore was extracted, and the north-east workings are down 1100 ft. Orebody is 40 ft. long and from 6 to 20 ft. wide. Probably several thousand tons are available above 900 ft. Ore was mined under agreement with United Verde Extension, which terminated on December 1.

Potash is reported to have been discovered near Walnut Springs, $3\frac{1}{2}$ miles from Jerome, by Tom Smart. The U. S. Bureau of Mines has been asked to investigate.

KINGMAN.—Cross-cut being driven west from the 250-ft. level of the Leviathan mine toward the Copper Wonder picked up a new vein 15 ft. from the station. This vein is 2 ft. wide, is high in molybdenite, and is similar in character to the main orebody. A pump is being lowered in No. 3 shaft of the Copper Wonder to secure increased water supply for the mill.

In the Aquarius mountains, the old Shipp mine, famous as a silver producer, has been re-located by Sitton and Murphy, who assert that the vein is rich in copper.

After developing large quantities of shipping ore on the Goldconda Extension, Walter H. Brown and associates will now arrange for a new milling plant.

Arrangements have been completed to develop the Standard Mineral Co.'s mine, formerly the Telluride Chief. A gas engine, compressor, pumps, and machine-drills have been ordered. There is about 2000 tons of ore on the dump. The company contemplates the erection of a 100-ton mill as soon as development is well under way.

NOGALES.—The Lower California Metals Co., a sub-company of the Sociedad Anonima de Metales, whose headquarters are in Mexico City, is operating here. The former company holds all the property in the United States, and acts as agent for the business affairs of the Sociedad Anonima, which have to be conducted in this country. At Nogales the company owns a 100-ton flotation mill of the latest type that has been erected for the treatment of ore coming from the mines of the Sociedad Anonima in north-western Mexico. The Lower California company also buys molybdenite ores in the United States for treatment at its plant.

OATMAN.—The Goldroad Bonanza company states that on the 550-ft. level the vein has been followed 125 ft. in milling ore, the last assays being \$14 per ton across 5 ft. No. 2 assessment of $\frac{1}{2}$ ¢. per share has been levied to pay for mining, erection of bins, etc., until treatment is commenced on April 1.

United Eastern Mining Co. in January produced 8100 tons of \$22.85 ore, a record. Recovery was 96.82%. On February 20 the 965-ft. level cross-cut reached the vein, where it is similar to the upper levels. War taxes for this company in 1918 will be about \$125,000.

Tom Reed company, cross-cutting from Aztec 500-ft. level, has opened 65 ft. of ore, 400 ft. south of Aztec. Only 12 ft. is profitable; 65 ft. assaying \$8; 5 ft., \$40; and 8 in., \$400 per ton.

PRESCOTT.—Old Dos Oris mine, with the Buzzard and Raven, 14 miles from Prescott, have been taken over by J. B. Tomlinson, representing an Eastern syndicate. They were owned by R. H. Burnister. In 1885 they suspended operations, due mainly to troubles in which litigation followed for years. Dos Oris was rated as the largest silver mine in Yavapai county, and with limited development in two years yielded \$166,000, and during the operation of the Buzzard and Raven, some \$30,000. Under new management, modern machinery will be installed.

RAY.—The Ray silver-lead mine, four miles by steep trail from this place, is shipping by mule-team a carload of ore daily. The property was located in 1878, and is known as the Haly-Suffern. A company headed by Captain William McDermott of Tucson now operates it. The carbonate ore assays 30% lead, with \$12 in silver and gold. J. Pollard is in charge.

South-east of Ray, also on a steep mountain, is the Ray Broken Hill mine, where an outcrop carrying silver, lead, and gold, with some copper, is being developed. Frank Schilling is manager.

Ray Consolidated has sunk a new shaft at a point convenient to stoping ground, to be used solely by miners, who now are compelled to climb long stairs in inclines at the principal shafts, taking time and adding to their fatigue. The new shaft, 512 ft. deep, is to have a double-deck Otis elevator. An arched double-tracked tunnel, a third of a mile long, buttressing against solidly shifting ground, has been finished in concrete on the third level of No. 2 shaft. Ore drops into a 500-ton bin, from which the skips are loaded almost automatically. Safety first is noted, as not a wire or pipe is visible, all having been hidden in conduits. Another feature of the mine is the substitution of air for former electric hauling. The new machines are of the H. K. Porter type, taking up to 1000 lb. pressure. The electric system carried 440 volts and caused fatal accidents.

SALOME.—Rich Hill Gold Mining & Milling Co. has been organized to operate the Old Johnson mine.

Argus Copper property, adjoining the Planet in the Swansea district of northern Yuma county, has been taken over by E. C. Lane and associates. Active development will be started at once, all necessary machinery now being on the ground.

Rich gold ore 600 ft. east of the old glory-hole, which started the first Salome excitement, has been made.

A carload of 20% copper and \$10 gold ore has just been shipped from the Vindicator mine of the Black Giant Mines Co. Vindicator shaft is down 80 ft., and shows 2 ft. of ore.

CALIFORNIA

Oil production of this State in January amounted to 292,860 bbl. daily, an increase of 14,000 bbl. over the December total. Stocks decreased 678,000 bbl. to 31,772,465 barrels.

ETNA.—I. J. Luce of Seattle, Washington, and John M. Tetherow of Grants Pass, Oregon, who recently acquired the Blue Jene gold mine of the Siskiyou Syndicate, near Etna, are erecting a stamp-mill and will be opening a large body of rich ore within 30 days.

FORBETOWN.—Butte Consolidated Gold & Silver Quartz Co. has been organized at San Francisco, with G. H. Homer as president and H. C. Freeman as secretary, to operate 10 claims in this district. Company is now ready to start exploration. An office is to be opened at Oroville.

GAZELLE.—Dewey mine, 8 miles from this place in Siskiyou county, has recently had power connected and surface plant overhauled. A good deal of \$5 to \$30 oxide and sulphide ore has been opened, enough to supply the 10-stamp mill and three Wilfley tables for several years. Some rich sulphide is sent to the Mammoth smelter in Shasta county. G. C. Brown is manager and E. H. Page superintendent, and have done good work in bringing the mine to its present stage.

GRASS VALLEY.—Empire Mines Co. has started construction of a tailing-dam. Residue will be prevented from flowing into Wolf creek by a concrete dam. It is estimated that the canyon will store tailing for 30 years at present rate of milling. Sixty stamps are dropping steadily, and most of the ore is coming from below 4000 feet.

MAOALIA.—Mineral Slide Gold Mining Co. has permission from State Corporation Commission to sell 15,000 shares at 20c. each, for cash.

NEVADA CITY.—Under control of Morgan & Leichter, the Oustomah mill has been overhauled, concentrators and special equipment added, and is dressing chrome ore from the Sweet property at Lime Kiln. Eight motor-trucks are delivering the ore, which is said to be of good grade.

PLACERVILLE.—Teddy Bear and Hot Spur gold mines, near the old Church-Union mine, 7 miles south of Placerville, is being developed by W. W. Milner and others of Seattle. When sufficient ore is opened a 50-ton mill will be erected. In Teddy Bear claim an adit cuts vein at depth of 135 ft., and from this point a winze is to be sunk to 350 ft. Vein is 10 ft. wide.

PORTERVILLE.—Freight embargo has resulted in suspension of work at calcining plants of American Magnesite Co. and Porterville Magnesite Co. Plant of Tulare Mining Co., 12 miles east of here, continues operating, as its product is disposed of in the West. The American company owns no mines, but calcines ore from other properties.

Lindsay Mining Co., headed by R. D. Adams and K. G. Gillette, has sold its mines and works in the Success district, 12 miles east of Porterville, to the Tulare Mining Company.

Magnesite shipments from this point are reduced to one carload occasionally, compared with three to five daily some time ago.

SONORA.—Owners of the Densmore mine await early start of operations by the Salt Lake, Denver, and New York investors who recently acquired possession under bond and option. During several years in the earlier days of quartz mining, the Densmore was a good producer, and was once owned by Alvinia Hayward and associates, who paid \$125,000 cash for it. Passing next into the hands of a local company, it was worked intermittently with indifferent results. It is situated 3 miles westerly from Columbia, and is equipped with a 10-stamp mill and other machinery.

Hope mine, just outside the eastern limits of Sonora, suspended operations indefinitely on February 1.

Sonora Wonder mine, sold lately to Frank Sollinsky and E. M. Blake of San Francisco, has been examined for the

owners by J. H. Morris. Two payments have been made, and the last is to be made shortly.

Rich ore has been opened in a 72-ft. shaft at a mine on the Jones ranch, near Shawmut. This is being developed by Francis Gage.

Activity in chrome mining in the western part of the county is steadily increasing; everywhere in the neighborhood of the chrome deposits prospectors are busy and locations are being made daily.

Work was commenced January 29 on the new adit that will open one of the rich ancient channels that traverse the property of the Springfield Tunnel & Development Co. The channel toward which the adit is being driven was prospected by means of a shaft, which had to be abandoned on account of excessive quantities of water. The portal of the adit is on the property of John Wight, which adjoins the company's holdings on the west. All rights necessary for carrying on work from the Wight place were recently secured by the mining company.

YREKA.—John Whitney is developing a chrome deposit near here and on an adjoining farm Mr. Irwin has shipped 25 tons of chrome, and will be a steady shipper. These two properties are reported to contain large deposits and high-grade ore.

Henry Wintering, superintendent for the Cliff, in the Yreka district, reports that much progress is being made in development and the mine will be a big producer in the near future.

COLORADO

BLACKHAWK.—Powers mine in Russell district is under lease to Robert Wilkinson and others of this place, who formed the Powers Mining, Milling & Leasing Co. An electric pump, air-compressor, and other machinery are to be ordered. This mine is said to be one of the best copper producers in Gilpin county.

Denver people have leased the Toronto silver mine in the Hughesville district, and will erect machinery. Stephen Hoskin is owner.

Silver Dollar mine in Russell district is to be re-opened by O. J. Duffield and others of Denver. Main shaft is to be sunk 100 ft. deeper.

BOULDER.—Owing to the high cost of supplies, the United States Gold Corporation, which is mining low-grade ore, is maintaining operations at a minimum, milling having been suspended.

BRECKENRIDGE.—Developments at the Royal Tiger mine, T. A. Brown superintendent, have been encouraging, and a mill is to be ordered at an early date.

CRIPPLE CREEK.—Roosevelt drainage-tunnel in January was extended 144 ft., and the Cresson cross-cut was advanced 105 ft. Face of tunnel is 60 ft. from Colorado City claim of Portland company.

Colburn mill is to resume treatment, employing a flotation method said to be patented by E. A. Colburn.

DENVER.—Crude oil from Rio Blanco County shale, distilled in Oklahoma, yielded 15% gasoline, 16% naphtha, benzene, and kerosene; 43% lubricating oil, and from 8 to 10% paraffin wax.

GROBORTOWN.—At the Colorado Central mine a 10 by 20-in. Blake crusher, two sets of 16 by 36-in. rolls, roughing jigs, Empire tables, trommels, etc., are being installed. Ore from the mine will be delivered from the Equator adit to the mill, which is to have ball-mills, Empire, Wilfley, and Deister-Overstrom tables, and a flotation plant. Ore carries lead, copper, zinc, gold, and silver.

Two feet of galena and iron pyrite has been opened on the 300-ft. level of the Onondaga mine. Besides this the company has good developments throughout the property.

IDaho SPRINGS.—Bonanza Mines Co. will develop the Bonanza claims on north slope of Albo mountain. George Taylor of Norton, Kansas, is president, and C. E. Angell of Independence, Kansas, secretary of this new concern.

IDAHO

BURKE.—Majestic Mining Co. is to resume work at its 13 claims north-east of this place. James Dunn is president. Ore carries lead and silver.

Hecla Mining Co.'s shaft is down 2000 ft., with 200 ft. to go. An additional depth of 1300 ft. is attained by driving in the Hecla, making a total depth of 3500 ft. Daily output is 1000 tons, of which 700 tons goes to the Gem and 200 tons to the Marsh mill. Crude ore sorted is up to 50 tons, and waste about 100 tons.

Federal Mining & Smelting Co.'s December operations resulted in a loss of \$108,381, against a loss of \$27,100 in November, and profit of \$31,076 in October, \$112,492 in September, and \$259,728 in July. The December loss was due to an accident to the Morning mine's shaft.

KELLOGG.—According to G. S. Anderson, manager for the Big Creek Mining Co., east of Kellogg, ore shipments are soon to be started. At 2350 ft. in the adit the vein is 12 ft. wide. A streak in this carries 72% lead and 73 oz. silver per ton. There is also some high-grade copper ore on the foot-wall. To handle second-class ore a crusher and hand jigs are to be procured, while equipment costing \$20,000 is proposed. This includes an aerial tram.

Bunker Hill & Sullivan M. & C. Co. is cross-cutting 500 ft. from No. 15 level, the deepest in the mine, to open ore workings on No. 14. No. 15 is 1200 ft. vertical below the Kellogg adit. The mill and smelter are working well.

WALLACE.—According to F. H. Skeels, manager of the Success mine, the orebodies below 1000 ft. are rarely continuous from one level to the next below. The shoots appear to be stronger near the ends of the vein and are found from 10 to 40 ft. from the granite contact. The widest points were on the 300-ft. level, narrowing at 600 ft., widening to the best ore at 1000 ft., and again narrowing at 1200 ft. From 1200 to 1600 ft. the ore is irregular, and the mine will probably be worked out at the latter depth. Up to July 1916, above the 1200-ft. level yielded 733,200 tons of ore, giving \$1,900,000 in dividends. Since then there has been a loss of \$150,000. Prospects in the east section are rather encouraging. On a 300-ton basis, all costs total \$5.42 per ton. Reserves total 18,300 tons, assaying 3% lead, 13.6% zinc, and 1.5 oz. silver per ton.

The Silver Range M. & M. Co. has been organized at Spokane with a capital of \$1,500,000. E. M. Burt, F. M. Williams, and Reuben Crandall of Spokane were incorporators.

WARDNER.—On the 600-ft. level of the East Caledonia the cross-cut has been driven 230 ft. since January 1, from which drifts are out 60 ft. each way on the vein. The workings are now under the shoot opened at 400 ft. R. J. White is manager.

MICHIGAN

HOUGHTON.—Quincy Mining Co. pays \$2.50 per share on March 25, against \$3 and \$5 for previous quarters.

Calumet & Hecla reports as follows for January:

Mine	Pounds
Ahmek	2,095,488
Allouez	737,779
Calumet & Hecla	6,111,104
Centennial	263,433
Isle Royale	1,038,562
La Salle	150,963
Osceola	1,309,533
Superior	179,837
White Pine	253,498
Total	12,140,197

MISSOURI

FLAT RIVER.—St. Joseph Lead Co. pays 50c. per share on March 20. Net income in 1917 was \$5,610,274. This is equal to \$3.98 per share.

JOPLIN.—Production of concentrate in the district last week was 4650 tons blende, 210 tons calamine, and 888 tons lead, averaging \$55, \$33, and \$84 per ton, respectively. Total value was \$340,259, making \$3,122,341 in seven weeks.

Lucky Shot Mining Co.'s mine north of Carl Junction is now owned by the Joplin-Sapulpa Mining Co. controlled by H. G. Beard of Sapulpa, Oklahoma. Ore is at a depth of 150 ft., and assays 15 to 20% blende.

SAGINAW.—Extensive operations are being planned by the Griffith Lead & Zinc Co. on its 750-acre tract, until recently held under lease by the Saginaw Mining & Leasing Co., near Saginaw. When the ground is drained and opened a 350-ton mill may be erected.

MONTANA

BUTTE.—Davis-Daly profit in January was \$125,000, against \$100,000 in December and \$56,000 in November. The Colorado mine shipped 175 tons daily, 40% being 12 to 15% copper ore from the 2300, 2400, and 2500-ft. levels. The Hibernia mine shipped 75 tons of silver-zinc ore; shipments are now 100 tons per day. The Hibernia shaft is being deepened from 400 to 600 ft. Sixty men are employed at the Hibernia and 300 at the Colorado mine. The Davis-Daly payroll is reported as \$60,000 per month.

Anaconda has reached 100% mechanical capacity in practically all departments. In labor efficiency, however, results are poor. Its production of electrolytic zinc has reached 100 tons daily, with prospects of increasing to 150 or 175 tons when market conditions demand.

Anaconda may have more labor troubles, as the local machinists' union voted on February 14 to strike unless the two men discharged last summer were reinstated. Electricians and other unions may strike in sympathy.

Butte Copper & Zinc Co. for 16 months ended November 30, 1917, reports gross value of ore sold \$1,535,163, of which \$510,150 was profit. Anaconda company was paid \$202,292 account of lease, also \$153,928 profit on lease. Net income at end of period was \$119,772.

PHILIPSBURG.—This district is shipping 500 tons of man-

MAP SHOWING SITUATION OF PHILIPSBURG, MONTANA

ganese ore daily to the East, and within two or three months this quantity will be doubled. The deposits are known to persist to 400 ft. Among the principal companies operating are the Philipsburg Mining Co., a subsidiary of the Bi-metallic Mining Co.; the Western Ore & Mining Co., back of which is the Cambria Steel Co.; the Beaver Creek Mining Co.; and the Morony Estate. The Philipsburg company is shipping daily about 125 tons, the Western Ore 100, the Beaver Creek 75, and the Morony Estate 60 tons. The Philipsburg company has completed the construction of a 300-ton concentrator,

which has been operating successfully on low-grade manganese ores for a while. A product of 40% manganese or better is aimed at from the milling of ores carrying around 30 to 35% manganese, with up to 15 to 20% silica. The general grade of the manganese shipments from Philipsburg is around 45%, with some shipments ranging higher.

NEVADA

COPPERFIELD.—Winze 30 ft. deep has been sunk on 8 in. of \$300 ore opened in the old State Line mine by Hiell, lessee, several weeks ago. At depth of 60 ft. from surface, vein is 4 ft. wide, maintaining the rich streak. Vein is considered to be extension of No. 4 of the Nixon-Nevada adjoining, in which there was 4 ft. of \$150 ore.

On No. 1 vein of Nixon-Nevada, where a winze is being sunk in the north drift, there is 12 in. of 50% copper ore. This and Washoe company may share in expense of proposed adit that is to prospect at depth a number of veins which run with and into the big dike or contact crossing both properties.

FALLON.—Silver-gold ore is reported discovered 28 miles south of this agricultural centre. Jack Davis of Reno has named the place Silver Cliff, and with others is organizing Silver Cliff Mining Co.

GOLDFIELD.—Jumbo Junior is extracting good shipping ore from the vein below the 880-ft. level. Vein is from 18 to 24 in. wide. Operations are conducted through the Jumbo Extension's Velvet shaft.

Driving east from the 1950-ft. level of Atlanta property is under way, and junction of Atlanta and West veins should be found within 150 ft., according to indications. Flow of water has lessened, and the manager, A. I. D'Arcy, is confident that a zone of enrichment will be opened. Prospecting of the Atlanta vein has been resumed at 1750 feet.

A. D. Parker, president of the Florence company, is to confer with the owners of the Red Hill-Florence over the vein recently opened by the latter. Red Hill-Florence maintains that the new vein has its apex in Red Hill territory and dips into Florence ground, but Florence people are inclined to assert part ownership. It is thought by leading men here that the two properties will be consolidated. The vein was discovered at a depth of 400 ft., and showed much rich ore.

LUNING.—Flotation plant near Luning and reverberatory furnace near Sodaville are to be erected, according to Mark Walser of the Wedge Copper Co. Eastern people are to do this, and the deal involves the sale of the entire property interests of the Wedge company and those of the Fermina Sarrias estate adjoining, also taking over the Darms coal property of 1600 acres at Coaldale.

On 1000-ft. level of the Calavada is an 18-in. vein of ore assaying 2% copper.

John Marcalja, leasing on Mary claim of Iroquois Copper Co., is now opening 19 to 23% ore, double that of recent assays. Shipments for months averaged 10%.

MANHATTAN.—In the apex suit of Morning Glory v. White Caps the latter won. It is reported in local mining circles that the Morning Glory company is to appeal. The case occupied court six weeks and cost the contestants approximately \$200,000. Six attorneys and several engineers and geologists were retained. The orebody was in a faulted limestone area. Decision practically makes vertical boundaries in this district.

NEW MEXICO

MOGOLLON.—Mogollon Mines Co. cut its No. 1 orebody on the 900-ft. level last week. This is nearly 200 ft. deeper than other openings. Grade and width are good. This vein shows a vertical extent of over 900 feet.

Oaks Co. is installing a compressor on its Deep Down property.

Construction at Socorro plant is being increased, and an effort is being made to have mill operating by May 1.

OKLAHOMA

Concentrate production of the zinc-lead region last week was 3046 tons blende and 482 tons lead, valued at \$208,150.

OREGON

GOLD HILL.—Herbert Brewitt and C. W. Scott of Tacoma, Washington, officials of the Manganese Mining Co. of that city, are here inspecting the new plant at their Lake Creek manganese mine east of here. Twenty men are employed. The company has recently spent \$30,000, and development promises to have an important bearing on this region. The poor condition of the road is hampering haulage to shipping point.

The McKinly copper mine, consisting of 12 claims lying 12 miles east of Gold Beach, has been sold by Delmer Colegrove and associates of Gold Beach, Oregon, to the owners of the Takilma Smelting Co. at Takilma, Oregon. These mines have long been known for their rich ore, and it is reported that the new owners will commence operating at once.

Hauling chrome and copper ore from the Waldo district to shipping at Water Creek on the Grants Pass-Crescent City railway continues only in a small way, on account of bad roads.

UTAH

Interest in oil-shale possibilities of this State continues. These deposits contain a much higher oil content than those profitably worked in Scotland and France. The oil-bearing beds of Utah are also thicker, and because of the peculiar topography of the plateau region where they are found are much more easily mined than are the foreign shales. Several experimental plants of limited capacity are being erected in Utah, all being adaptations of the Scotch method of distillation.

ALTA.—At the second annual meeting of the Emma Consolidated Mines Co., held at Wilmington, Delaware, George Graham Rice was re-elected president, W. B. Ridgely vice-president, and J. H. Weinberg secretary. To January 23, 1918, shipments totaled 9124 tons of ore averaging \$27.29 per ton, smelter settlements realizing \$253,226.

BINGHAM.—For failing to report on time at the Utah Copper Co.'s mills, 157 men were recently discharged; but were reinstated by the general manager, R. C. Gemmell. A dispute over the train schedule brought on the trouble.

Yampa mine of Tintic Mining & Development Co. will close for good on March 1. This has been a large producer.

EUREKA.—Arrangements are almost completed for exploring a large tract of mineral land in the Erickson district, some distance west of Eureka. The new company to be organized for this work is to be known as the Majestic Copper Mining Co. It will have a capitalization of \$1,000,000, shares \$1 par. Associated with Charles Stauffenberg will be Harry Webber Jr. of New York and C. S. Humphreys of Chicago, as well as other prominent Eastern people. This property was located many years ago by William Stauffenberg, one of the pioneers of this district, who died about a year ago. It has been opened to some extent, and disclosed some splendid copper ore.

TINTIC.—The Tintic Milling Co. shipped 31 tons of bullion worth \$1200 per ton to Eastern refineries. This is the result of two weeks' work.

The Tintic Drain Tunnel Co.'s adit is in 200 ft. in loose porphyry. Hand drilling has been done so far. Two shifts are employed.

WASHINGTON

CHEWELAH.—Washington Water Power Co. has arranged with the Stevens County Light & Power Co. to provide power for the magnesite quarries and copper mines of this

county. The power will be taken from the recently completed plant at Long lake, 20 miles south of Spokane.

REPUBLIC.—Among the papers read at the recent convention of the Northwest Mining Association at Spokane was one by E. L. Tate, entitled 'Future of Republic Camp.' Those who have watched the ups and downs of this district should secure a copy of the address.

The Knob Hill company shipped about 530 tons of ore during January. This ore came from the 200-ft. level and assays from \$9 to \$15 per ton.

AFRICA

TRANSVAAL

JOHANNESBURG.—Cables on February 16 report tremendous rain in this and other parts of South Africa. Johannesburg received 14 in., but mining operations were not hindered much.

CANADA

BRITISH COLUMBIA

ANYOX.—At the Granby company's smelter extensions are being made to the furnace and converter buildings. A new copper-casting machine is in use. The 20-ft. converters have not arrived, the slag-haulage system has not been started, and the slag-casting machine remains to be erected. Payrolls of the Granby company for operation of the mines and smelter at Anyox were more than \$2,000,000 in 1917, according to 'Granby News,' an official monthly.

KALSO.—On February 1 the Utica company shipped a carload of ore to the International smelter at Tooele, Utah. The estimated metal content is 200 to 225 oz. silver, 20% lead, and 15 to 17% zinc, the lot valued at \$12,000. C. B. White is superintendent.

TRAIL.—During the last 10 days of January the Consolidated company's smelter received 11,547 tons of ore. The Centre Star, Rossland, contributed 3498 tons, Le Roi, 3369 tons, and Sullivan, 1858 tons of zinc ore.

ONTARIO

COBALT.—Kerr Lake company produced 204,641 oz. silver during January, against 203,048 oz. in December.

The Adanac Silver Mines Co. on February 14 increased its capital from \$2,500,000 to \$3,000,000. The money raised is for further exploration.

CHILE

Cerro de Pasco company has declared a quarterly dividend of \$1 per share, plus an extra of 25 cents.

Braden Copper Co. produced 6,200,000 lb. in January, compared with 4,798,000 a year ago, and 5,836,000 lb. in December. Grading of the railroad, to connect the Andes Copper Co.'s mine with ocean transportation, has been about finished, and with the equipment of this line, material for the quick development of the orebodies will be rushed. It will be two or three years before production is started.

MEXICO

SONORA

CANANEA.—Cananea Consolidated Copper Co., Montezuma Copper Co., Democrata Mining Co., and El Tigre Mining Co. have been granted permission to pay employees and all State obligations with United States silver coin, silver certificates, or Federal Reserve notes.

Greene Cananea Copper Co. produced in January 3,130,000 lb. copper, against 1,650,000 lb. in December. From July to November, inclusive, the property was closed owing to differences with the Mexican government, but is now getting into its old stride.

EL TIENE.—On February 7, at Kansas City, Missouri, the Lucky Tiger Combination company declared its regular monthly dividend of 5c. per share, plus an extra of equal amount. January earnings were \$68,000.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

JAMES P. GASKILL is at Los Angeles.

AUGUSTUS LOCKE is at Mazatlan, Mexico.

OTTO SUSSMAN is at Blackwell, Oklahoma.

F. A. RICHARDS is here from South Porcupine.

ANDREW MCFARLANE of Tucson, Arizona, is in New York.

WALTER DOUGLAS has returned from Arizona to New York.

LEON J. PEPPERBERG is in the oilfield of Mineral Wells, Texas.

W. W. MEIN has returned from Copper Cliff, Ontario, to New York.

CHARLES JANIN has returned from Washington to San Francisco.

M. A. PETERSON, of the United Verde, Extension, is at Pittsburgh.

ALFRED E. BROOKS, Major in the Expeditionary Force, is in France.

JOHN A. RICE has returned to San Francisco from Cananea, Mexico.

A. G. MCGREGOR is making a trip of inspection through Peru and Chile.

E. GYBSON SPILSBURY has moved his office to 29 Broadway, New York.

J. H. G. WOLF is acting in an advisory capacity on oil at Washington.

C. S. MCKENZIE has joined the 27th Engineers at Camp Meade, Maryland.

J. K. TURNER is a member of the Federal Exemption Board for the State of Nevada.

H. VINCENT WALLACE has returned from Mexico and is now residing at Los Angeles.

F. L. RANSOME is at Bisbee, on his way to examine the Terlingua quicksilver district in Texas.

H. C. ENOS is making examinations of mining properties in the State of San Luis Potosi, Mexico.

SEELEY W. MUND, Major in the Engineer Officers Reserve Corps, is now stationed at Washington.

O. E. LEROY, economic geologist for the Canadian Geological Survey, has died of wounds in France.

HENRY U. BROSSEY has been elected second vice-president of the Detroit Graphite Co., at Detroit, Michigan.

J. G. ALEXANDER has returned to Nacozari to resume the management of the Nacozari Copper Company.

WILL C. HIGGINS, editor of the 'Salt Lake Mining Review,' passed through San Francisco on his annual tour.

THORVALD J. ANDERSEN of New York is in San Francisco, on his way to La Grange, Stanislaus county, California.

O. D. WELSH, recently at Anyox, B. C., has enlisted with the 319th Engineers at Camp Fremont, California.

J. W. WRIGHT has been appointed Second Lieutenant in the U. S. Medical Reserve Corps at Deming, New Mexico.

POPE YEATMAN has succeeded EUGENE MEYER Jr. as metal expert on the Council of National Defense, at Washington.

RUSH M. HESS is examining manganese deposits in the south-eastern States, with headquarters at Anniston, Alabama.

R. S. HANDY, superintendent of the Bunker Hill & Sullivan mill, is acting in an advisory capacity at the Alaska Juneau mill.

LAWRENCE and ARTHUR HASTINGS, two sons of JOHN B. HASTINGS, are privates in the American Expeditionary Force in France.

GEORGE H. GARRY, formerly of the U. S. Geological Survey and at present consulting geologist for the Tonopah Belmont company, is making a geological examination of the Tonopah Midway Mining Co.'s property.

THE METAL MARKET

METAL PRICES

San Francisco, February 20

Aluminum-dust (100-lb. lots), per pound.....	\$1.00
Aluminum-dust (ton lots), per pound.....	\$0.90
Antimony, cents per pound.....	15.50
Antimony (wholesale), cents per pound.....	13.50
Electrolytic copper, cents per pound, in carload lots.....	23.50
Electrolytic copper, cents per pound, in small quantities.....	24.67
Pig-lead, cents per pound.....	7.25—8.25
Platinum, soft and hard metal, respectively, per ounce.....	\$108—118
Quicksilver, per flask of 75 lb.....	\$115
Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	17.50

Antimony imports into the United States during 11 months of 1917 totaled 19,995 tons, compared with 13,049 tons in all 1916. Metal in warehouse on November 30 each year was 4398 and 1511 tons.

Recent bidding for two Government contracts for antimony—30,000 and 100,000 lb., respectively—brought out a large number of bids, the lowest for these being 13.75 and 13.87½¢, per lb., from the same firm. Prices ranged up to 15.75 cents.

ORE PRICES

San Francisco, February 26

Antimony, 45% metal, per unit.....	\$1.05
Chrome, 34 to 40%, free SiO ₂ , limit 8%, f.o.b. California, per unit, according to grade.....	\$0.60—0.70
Chrome, 40% and over.....	\$0.85—1.00
Magnesite, crude, per ton.....	\$8.00—10.00
Manganese, basis 40 to 44% Mn and 8% SiO ₂ , cents per unit.....	70.00—80.00
Tungsten, 60% WO ₃ , per unit.....	26.00
Molybdenite, per lb., 85% MoS ₂	\$2.15

Chrome production of the United States in 1917 totaled 47,935 tons, nearly all from California and Oregon. Imports were 115,945 tons.

EASTERN METAL MARKET

(By wire from New York)

February 26.—Copper is quiet. Lead is inactive, though firm. Spelter is dull, but steady. Platinum is unchanged at \$108 to \$116.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending	Date	Average week ending

Tone of silver market at end of January was easier in London, according to Samuel Montagu & Co. As the demand was fairly good, though not active, lower prices were attributed to freer supplies of the metal. Exchange with Shanghai, where a certain amount of speculation is rife, did not move in sympathy, but actually hardened. Stocks at Shanghai were 27,700,000 oz. as bars and \$13,000,000 (Mexican). Issue of one rupee notes (32 cents) in India is a success, and is relieving the silver situation. Continued shrinkage of Indian Treasury holdings of silver, and the impossibility of silver supplies expanding correspondingly to the abnormal demand for coinage, render the note-issue timely.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Tin imports during 1917 totaled 68,996 tons, compared with 66,824 tons in 1916. Of this, 74% came from England and the Straits. Holland contributed 20%.

Eastern Metal Market

New York, February 20.

Milder weather has continued another week in this part of the country and has been a great aid in relieving railroad congestion, the coal shortage, and industrial troubles. This, combined with the fact that the last of the heatless Mondays was over a week ago—temporarily at least—has imparted a better tone to the market, and affairs are nearing normal war conditions. All markets, however, continue quiet.

Copper output has lessened, and a temporary scarcity exists for domestic consumers not having war work.

Tin is still scarce for spot delivery, but inquiry for and business in futures are active.

Lead is strong, but not active.

Zinc continues lifeless but steady.

Antimony is again lower on poor demand.

In the steel industry conditions are improving decidedly. By the end of this week operations will probably be at 80% capacity. As the time draws near (April 1) for a reconsideration of Government prices, the trade keenly hopes that Washington will not strive further to destroy incentives to maximum output. Mounting costs and restricted operation for several weeks will make it hard to meet capital charges of the first quarter. A three months period of price-fixing is regarded as too short. With only five weeks left before entering the next period, few new commitments are expected. Pig-iron buying in large volume is being restrained by the conservative attitude of makers.

COPPER

There appears, on the surface, to be a temporary shortage of copper. This is inferred from the fact that the Copper Producers Committee has recently restricted shipments and sales to consumers not having Government work. While this class of consumers is not extensive, they have been supplied lately regularly with what they needed, but this has been restricted recently. The cause is understood to be lessened output, though facts are as hard to obtain as ever. Evidently railroad congestion, severe weather, coal shortage, and other industrial troubles have interfered with the normal output of both refined and raw copper—this is admitted by one large company. Supporting this probably is the statement that the January output of 15 companies was 9,200,000 lb. less than in that month of 1917. The restriction or shortage is believed to be only temporary. Government prices of 23.50 and 24.67½c. continue to rule. It is understood that large contracts for shells and war munitions are about to be placed by the Government, and will require a large amount of copper.

TIN

Market has been quiet in the past week, and sales are reported to have been light. Sellers are not numerous and consumers are becoming anxious as to their future supply. High prices for all grades are a cause of reluctance to enter the market. On Monday of this week there were sales, in moderate quantities, of all grades except Straits tin; while yesterday was a quiet day. Off-grade tin is in good demand, and consumers are buying freely, especially Chinese tin, the production of which was said to be at a new rate. The fact that off-grade tin is not up to Government specifications is the reason why the demand is so good; it is not liable to be commandeering. It is possible that one or more cargoes of tin have been sunk recently. A reason for this probability is the fact that in the past week the London market soared to £227 per ton for spot Straits—a record price. This was a source of some anxiety here, and resultant higher prices. A week ago

the quotation in London was £308, but by yesterday it had fallen to £316. The previous high price—a few weeks ago—had been £309. Arrivals to February 19, inclusive, were 850 tons, with 4900 tons estimated afloat. Spot Straits tin continues nominal at about 85c. per lb., New York.

LEAD

Market continues dull but quite firm. Advance of the leading producer—A. S. & R. Co.—early last week, reported in our last letter, has not affected the market as it often has. Its new price of 7c. has usually been raised by the outside market by at least ½c. per lb., the increase this time has been but slight. Quotation by independents is about 7.10c., New York, or 6.95c., St. Louis. Spot lead has sold at 7.12½c., New York. There has been fair buying of small lots because of delayed shipments from the West, and these have gone at 7.12½ to 7.25c., New York, for carloads. Sellers are not anxious to do business unless the buyer can procure a shipping permit. Lead exports in January are reported as 6939 gross tons.

ZINC

The feature of the zinc market since writing last has been the announcement from Washington that a price of 12c. per lb. for grade A zinc has been agreed upon between the War Industries Board and producers, but subject to revision June 1. The official statement, as foreshadowed in this letter, was made by the President last Thursday. The usual stipulations are laid down, and conditions imposed. Sheet-zinc was also fixed at 15c. per lb. base, with plate-zinc, which is sheet-zinc ½ in. thick and heavier, fixed at 14c. per lb. Settlement of the grade A price, after over eight months of suspense, is a source of relief as well as satisfaction. A fair profit is obtainable for makers of grade A, as well as of sheet and plate-zinc. The grade A price is not as high, of course, as some had hoped for. It is estimated in the trade that while the spread in August 1914 between sheet-zinc and prime Western, St. Louis, was only 2.15c., it is now 7.25c., or the difference in one case between 7 and 4.85c., and in the other between 15 and 7.75c. The general zinc market is as dead as ever. The Government is buying and absorbing large quantities of grade A and other grades, but other buying is not large. Regular consumers are spasmodically purchasing prime Western and special brands in small amount, as their immediate needs require. These constitute galvanizers, brass-makers, and others. The quotation for prime Western is unchanged but firm at 7.75c., St. Louis, and 8c., New York, for early delivery, with future positions a little higher. Zinc exports for January are reported as having been 10,550 gross tons.

ANTIMONY

In the absence of any demand the market is lower at 13.50 to 13.75c., duty paid, New York, for Chinese and Japanese grades for prompt or February delivery. The market is somewhat unsettled.

ALUMINUM

With the market lifeless and with no increase in demand, No. 1 virgin metal 98 to 99% pure, is steady and unchanged at 36 to 38c., New York, for prompt delivery.

ORES

Tungsten: Prices are unchanged at \$20 to \$26 per unit in 60% concentrate, the higher price being asked for scheelite. Sales of wolframite have been fairly liberal in the past week. To what extent the new proclamation on licensed exports and imports will affect the tungsten or other ore-markets is as yet difficult to say. Ferro-tungsten is unchanged at \$2.35 per lb. of contained tungsten.

INFLUENCING MEN IN BUSINESS: THE PSYCHOLOGY OF ARGUMENT AND SUGGESTION. By Walter Dill Scott, Ph.D. Second edition. Pp. 186. The Ronald Press Co., N. Y., 1917. For sale by MINING and SCIENTIFIC PRESS. Price, \$1.50.

Dr. Scott is right in claiming that business success is chiefly dependent upon the ability to influence men. The American people have been interested in men mainly for the sake of getting something out of them, which is at the root of business. They have not been interested in men as men to anything like the extent that they have been interested in men as potential placers of orders for goods. It is difficult to dissimulate in this matter, wherefore the American has developed a brutal type of frankness, which is usually regarded as a particularly American virtue. The Frenchman, on the other hand, is seriously interested in other men, and this interest is quite largely independent of any knowledge as to the persistence of the person in question. The result is a special *bonhomie*, which has proved one of the most useful factors in the commercial advancement of the French people. When the American undertakes to imitate this adroitness to win the confidence and favor of others, he usually does it with self-consciousness, which is likely to prove damaging to his interests. It is in the analysis of such relations as these that Dr. Scott's book becomes valuable, and it is to be commended to all young men as a stimulating guide toward that knowledge of human nature which, coupled with sincerity and diligence, will lead to success.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

CONCRETE SHIPS

The Portland Cement Association of Chicago has just issued a pamphlet entitled 'Concrete Ships,' which is of great interest at this time, when the building of reinforced concrete vessels is becoming an important factor in helping to solve the shipping problem. Some of the more striking features of this pamphlet are here presented.

Concrete is a ship-building material that can be quickly and readily obtained in large quantities, and the idea of concrete ships is neither new nor fantastic. There are many reasons why concrete is a logical material for ship construction. Sev-

finished far enough to float the unloaded vessel. Sand, stone, cement, steel reinforcing bars, and structural-steel shapes are on the market, and usually may be obtained promptly. Therefore, the materials required for concrete-ship construction are generally and readily available.

Most of the labor necessary to build concrete ships is of the cheaper grade. Expert supervision is needed with any ship construction, but the number of skilled artisans required for concrete shipbuilding is small. Calking, heavy framework and bracing, fitting of plates, and shaping of planking are entirely eliminated in concrete ship construction. As the time required to construct a sufficient portion of the hull to permit floating

VIEW OF HULL OF 400-TON MOTORSHIP BUILT BY THE FOUIGNER COMPANY, NORWAY

eral of these are especially applicable to the present situation: the materials required for constructing concrete vessels are available in necessary quantities, all along our coasts and waterways; little skilled labor is required; concrete vessels can be constructed rapidly, are reasonable in cost, will not burn, and are rot-proof and rat-proof.

Ship hulls must be made of a material that is stiff enough to prevent buckling between ribs. Concrete will accomplish that end. Shaping it to conform to the lines required is merely a matter of depositing it between forms having the desired lines. It can be finished so smooth that skin-friction will be reduced to a minimum and sea growths will find no opportunity for attachment. Concrete in its plastic state lends itself to any shape. There is no joining as required with wood. There are no rivets nor bolts to be loosened by jars or strains. Reinforced concrete uses steel most effectively and economically. More than ordinary speed in construction is made possible because the skeleton of reinforcement may be placed quickly and the ship launched as soon as the hull has been

the vessel is very short, because of the speed with which concrete may be placed, it is possible to make use of dry-dock facilities, allowing the vessel to float as soon as possible, and then to bring up material on scows and barges, thereby materially lessening the amount of handling of materials and increasing speed of construction.

As will be seen from the following examples of boats and barges now finished or under construction, the practicability of concrete for such structures is not questioned by those familiar with its possibilities. Concrete may be applied to or used in connection with the reinforcing framework of the hull by either of two methods: (1) Mixed and then placed in forms in the same manner as in the construction of buildings; (2) applied by means of a machine such as the cement-gun or similar apparatus, using compressed air or steam under pressure. In such cases fewer and simpler forms are required.

Early in 1917 a group of San Francisco capitalists formed the San Francisco Shipbuilding Co., to undertake the construction of sea-going vessels of concrete. The company is now

building an ocean-going cargo-vessel of nearly 5000 tons, that will be about 330 ft. long and 46-ft. beam. In constructing this vessel the reinforcement was welded together, thus reducing to a minimum the quantity of steel required, by avoiding laps that otherwise would have been necessary. Plans for this work were developed by Allan McDonald, of McDonald & Kahn, San Francisco. The original drawings indicated that the reinforcement used weighs less than the bolts needed in a wooden ship of equal dimensions, and that the

Works. The Porsgrund plant builds the boats bottom up, an internal mold being used which is made in units that can readily be taken apart and re-assembled. Such a vessel is launched in the same position in which it is built, that is, bottom up, and by taking advantage through a special arrangement of interior compartments, a small amount of water is admitted so that the vessel soon after being launched rights itself. The general structure of the vessels is a series of transverse ribs with a thin shell, and because of the fact that

VIEWS TAKEN OF THE LAUNCHING AND SELF-RIGHTING OF A

hull will weigh less than that of a wooden ship; 2500-hp. turbine-engines equipped with reduction gears will be used as motive power. Progress in the construction of this, the largest concrete vessel yet to be built, has recently been shown at motion-picture theatres throughout the country. It is expected that work will be finished and the vessel launched early in 1918.

Companies have been formed in Bergen, Norway, and Buenos Aires, Argentina, to build concrete vessels after the same plans used in Norway at the Porsgrund Cement Casting

it is cast bottom-side up, it is easier to control the density of the concrete along the bottom and lower side of the hull; consequently thinner sections can be used than might otherwise be possible.

The launching of such a 200-ton lighter was briefly referred to in a Norwegian paper as follows: The launching was done after heretofore unknown methods, namely, by letting the ship go into the water bottom up. This method was tried for the first time after calculations by the cement-works superintendent, Engineer Alfsen. The launching was a great success,

and came out exactly as calculated. The barge of 200 tons capacity used about 15 to 20 minutes to right itself.

A series of photographs reproduced herewith illustrates several stages of the launching. 'Shipping' (New York), of November 3, illustrated by the above sketches, *A, B, C, D*, and *E*, the principles of launching, which were described as follows: The diagram *A* represents a section of the vessel immediately on taking the water. The inner mold divided into compartments is seen, together with the outer reinforced

unstable equilibrium, the centre of gravity being considerably higher than the centre of buoyancy as shown. If, now, from any cause whatever, the vessel heels to one side or the other, the weight of the hull and its contents, acting through the centre of gravity, and the pressure on the submerged area acting through the centre of buoyancy, form a couple, the moment of which tends to turn the vessel on a longitudinal axis as shown at *C*. The moment of this couple has its maximum value when the vessel is in the position shown at *D*, after

200-TON CONCRETE BARGE IN THE HARBOR OF FORSGRUND, NORWAY

concrete hull of the vessel, and it will be observed that as yet there is no water in the middle compartment of the mold owing to the air not escaping rapidly enough through the vent pipes. As the air escapes, however, the water rises in this compartment, the vessel gradually sinking as it loses its buoyancy, until the water reaches the level of the two upper side-compartments which are also gradually flooded, so that a position is gradually reached, as shown at *B*, when the vessel is submerged to its maximum amount. The lower side-compartments are never flooded, and thus the vessel is in a state of

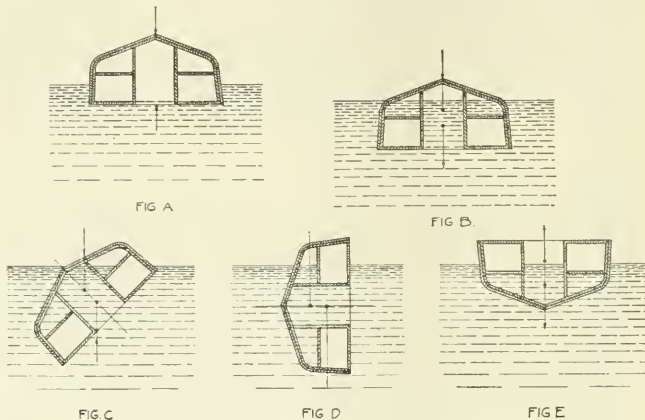

which it gets gradually less and less until the vessel floats in the correct position as shown at *E*, when the moment of the couple is again zero, but the vessel is now in a state of stable equilibrium. The slightest list to one side or the other, after the vessel has been launched and the compartments filled, is thus sufficient to cause her gradually to heel completely over until she floats in a normal position. The flooded compartments are then pumped out, and the mold is removed, this being used again in the construction of another similar vessel.

Few persons are aware of the fact that the first example of

what today would be called reinforced concrete was a boat. In 1849 there was built by M. Lambot, of Carces, France, a row-boat which was nothing more nor less than reinforced concrete. This piece of work marked the starting point of the history, not only of concrete boat-building but of reinforced concrete. The process of construction was patented and its maker exhibited his work at a world's fair held at Paris in 1855. It is said that this boat is still in service. M. Lambot's work was investigated by the French government in 1850 but, as is often the case, further development was left to private initiative. In 1899, Carlo Gabellini, of Rome, Italy, began the construction of concrete scows and barges. His process had been so developed by 1905 that a 150-ton barge was constructed for the city of Civita Vecchia. The following year another barge was built for the military harbor at Spezzia, for the Italian navy. This barge, before acceptance, was put to the severe test of being driven against some piling and afterward being rammed by a steel tow-boat. Results of these tests were so satisfactory that construction of similar boats or barges followed. The

3-in. bulkheads extending from bow to stern. Reinforcing consisted of $\frac{1}{2}$ -in. square deformed bars covered with $\frac{1}{4}$ -in. No. 12 wire-mesh. Reinforcing was suspended in place from wooden beams and properly located by constructing a wooden platform placed at an elevation corresponding to the bottom of the barges. Bars were placed on 9-in. centres lengthwise, and 12-in. centres crosswise, after which the platform was removed and the network of reinforcing covered with wire-mesh. A $\frac{1}{2}$ in. coat of cement-mortar was then applied to the wire-mesh. Ten running feet of the barge-length for its entire width was built up at one time.

In 1909, the United States occupied such an insignificant place in the shipbuilding world that the output of our yards fell below those of Japan. In that year, England led by producing 76% of the world's bottoms. Germany was a poor second; Japan a worse third. American ingenuity, organization, and enterprise is now being directed toward supplying the world with ships. Suitable lumber and timber are not quickly obtainable. Steel mills are overloaded with work. The ship-

DIAGRAMS ILLUSTRATING PRINCIPLES OF LAUNCHING BOATS, BOTTOM UP

first step in 'laying down' these vessels consists of placing reinforcement for the keel and ribs. This reinforcement, which usually consists of round steel rods, is then covered on the outside with $\frac{1}{4}$ -in. wire-mesh, to which a 1-in. coat of cement-mortar is applied by hand. Next, a somewhat thinner coat of mortar is placed on the inside, following which forms for the ribs and keel are put in place and concrete deposited for these parts of the vessel. These ribs run both longitudinally and transversely so that a checkerboard arrangement results, the pockets being 10 in. deep and the ribs about 2 in. wide. Over these ribs $\frac{1}{4}$ -in. wire-mesh is placed with a thin mortar-covering plastered on. Finally a third and coarser wire-mesh is pressed into the soft mortar and the entire surface troweled over. This completes the hull. Bulkheads are next concreted and the boat finished with a wooden sheer strake and gunwale.

Concrete barges built on the Panama Canal in 1911 proved good examples of what service such barges could render under adverse conditions. In this case concrete was selected as the construction material because no skilled labor for steel or wooden ship construction was available, nor could steel plates nor suitable seasoned timber be obtained within the time required. The design of these barges called for a structure 64 ft. long by 24 ft. wide, with a depth ranging from 5 ft. 4 in. to 5 ft. 8 in. Walls were made $2\frac{1}{2}$ in. thick because the barges were intended for use merely as floats to carry suction pumps and engines. The only bracing of the hull consisted of two

building material that can be obtained in ample quantities in many localities at reasonable prices is concrete. It has been tried and found satisfactory. All that now remains is for energetic and farsighted marine engineers, shipbuilders, and designers in reinforced concrete, to work together in applying the knowledge which each has in his particular field to the requirements of shipbuilding. American ingenuity will not balk at the new problems that may arise. That they can be solved is now fully demonstrated.

'Continuous Filtration with the Portland Filter' is the title of Catalog No. 28-C, 1918, of the COLORADO IRON WORKS Co., of Denver. This machine was first operated on a large scale at the Victor mill of the Portland Gold Mining Co., near Cripple Creek, and has since been installed at many mills and chemical works. Drum filters are so well known that no detailed description is necessary, beyond some special points claimed for the Portland type. Sizes vary from 6 ft. diameter, 24-ft. face, and 45 sq. ft. filter area, to 14 ft. diameter, 20-ft. face, and 880 sq. ft. filter-area. Quantity filtered may vary from 200 to 1200 lb. of dry material per square foot of filter-area per 24 hours. Slime can be reduced in moisture from 50 or 60% to 15 or 20%. The makers claim that the filter-valve is the simplest for this work. Panels are effectively isolated from one another, and wire winding is improved. Some interesting sketches and data are given, and the publication is a great improvement on previous ones.

IN order to make room for Mr. Mackenzie's letter on Alaska Juneau affairs we have dropped one page of editorial.

ROASTING of ore is assuming greater importance with the increase in reverberatory smelting, and this practice is destined to grow still more rapidly in the future by reason of the modern tendency to utilize the fume in the manufacture of sulphuric acid. Every contribution to the subject of roasting is therefore interesting, and Mr. R. A. Watson has contributed a most useful article to this issue describing the new plant just erected at the Humboldt smelter in Arizona. We regret that a typographical error was made in the author's initials.

WHATEVER doubt may have been entertained in any quarter as to the sincere and close attachment of Austria to the destinies of Deutschthum will have been dissipated by the fact that Austria appears as the chosen instrument for communicating the German ultimatum to Rumania. The terms of peace, as stated by Count Czernin, the soft-spoken angel-trumpet of the Teutons, reveal commercial benefits in Rumania to be shared by Germany and Austria in such manner that it must now appear to everyone how inextricably interwoven are the purposes of the two Central Powers.

FEDERAL mediator Meyer has denied the petition of the miners and mechanics at Jerome for a horizontal increase of \$1 per day in wages. He finds the costs of the necessities of life at Jerome to be less than at Fort Worth, Texas, the comparison being made with Mr. Meyer's home-town, concerning which he is fully informed. The criticism of the wretched habitations of the workers, recently made in the MINING AND SCIENTIFIC PRESS, is confirmed by the mediator, who declares that rentals are 40% too high, and that it is the duty of the principal mining companies to provide better and cheaper cottages.

COPPER exportation from the United States reached the big total of 1,110,975,000 pounds, or 550,487 tons, in 1917. This represents 60% of the domestic mine production of copper last year. Shipments overseas in

January are given as 115 million pounds, showing that the rate of exportation to our Allies continues undiminished. In 1913 Germany imported 310 million pounds from us, and in 1914 she managed to get nearly 200 million pounds before the seas were closed to her traffic. The bigness of our exportation of copper is further emphasized by the fact that these metal statistics do not include the copper shipped in the form of brass and finished products.

PLATINUM has been commandeered by the Government, and extraordinary efforts are being made to increase the supply, since the main dependence of this country has been upon the Russian resources, now closed to us by the circumstances of war. The metal at present is used chiefly as a catalytic agent in the so-called contact process for making sulphuric acid, and the shortage has become acute. Several thousand ounces could be consumed immediately, whereas the usual output of this country is only 700 ounces per annum, derived as a by-product in the working of gold placers. Mr. L. M. Prindle of the United States Geological Survey, has recently been investigating the possibilities of increasing the production from the gravels and beach-deposits of California and Oregon. Strenuous efforts are being made to encourage the development of these resources, and everyone that can add to the supply is urged to do so, even if he can contribute only a few ounces. The use of platinum in jewelry is prohibited.

ENERGETIC exploration and intensive development of certain needed mineral resources is earnestly recommended in a circular just issued by Mr. Franklin K. Lane, Secretary of the Interior, entitled 'How to Save Ships.' The purpose in view is revealed by that caption; ships are too urgently required for transporting troops and supplies to Europe to admit of dependence upon foreign sources of such metals and minerals as can be obtained in this country. Mr. Lane points out that their importation not only diverts shipping from the trans-Atlantic service, but produces a further demand for fuel and mining equipment abroad. The minerals specified are manganese, flake graphite, tin, tungsten, antimony, pyrite, magnesite, potash, and nitrates. A proposal has been made, and has received official en-

dorsement, for extending Government aid in the exploitation of such deposits, but it has not yet become law. Meanwhile, the remunerative prices obtainable for these products should encourage a prompt response, quite apart from the patriotic incentive that should bestir every true American to do all that he can.

JEROME J. DAY, of the Hercules mine, in the Coeur d'Alene, has established a scholarship in the School of Mines of the University of Idaho. The scholarship is for \$250 per annum to run for four years. It will be awarded annually, so that four scholarships will be in effect concurrently. It is to be awarded to high-school students in Shoshone county, Idaho, the winners being selected by an examination to be held annually at Wallace. Not scholastic ability alone but manliness and character generally will be considered in making the award. We take pleasure in referring to this public-spirited act, because it sets an example that other successful miners should follow. In this connection the gift of \$1,000,000 by Mr. Andrew Carnegie to McGill University is noteworthy. Mr. Carnegie states that he has been moved to this benefaction by the devoted service of the University during the War and the sacrifice it has made toward Canada's part therein; he also wishes his gift to be considered "an expression of appreciation and sympathy for the people of Canada on the part of their allies south of the border." All of which is well done, for McGill is a great and useful institution, and, as for Canada, we are proud to live next-door to her.

OUR ambassador to Spain, Mr. Joseph E. Willard, has been doing effective work. He has reached a satisfactory reciprocity agreement with the Government to which he is accredited, whereby supplies from Spain will be forwarded to our troops in France, in exchange for equipment to rehabilitate the Spanish railroads, as well as for lubricating oils of various kinds, and other needed materials. The King is reported to have taken a personal interest in smothering the discord that had arisen, which is not surprising in view of his previous efforts to stem the pro-German tide in his dominions. As we predicted recently, the elections have returned a majority for the party favoring a neutral attitude, which means that the influence of the Count of Romanones and the Marquis of Albuernas, both of whom are friendly to the Allies, is in the ascendant. The new treaty should open many opportunities for American engineers and mechanics. Our help is needed to improve the operation of the railroads; likewise American capital and experience should contribute to the rapid development of the coal deposits, which have been shown by recent explorations to be extensive and valuable. More than this, our friendly co-operation with Spain will promote an increase in the cordiality of our relations with the Spanish-American republics, which draw more inspiration from the mother country than our people generally have realized. Pan-Hispanism is more than a word; it expresses a definite movement that has taken concrete

form since the outbreak of the War in many organizations for the encouragement of commercial and intellectual intercourse between the several Spanish-speaking countries. Both in the Americas and in the Iberian peninsula these peoples control large undeveloped resources to the unfolding of which we, more than any other nation, by virtue of our geographical and other relationships, should contribute effectively.

AMONG the interesting features of mining in the zinc region of Oklahoma is the financial participation of the Indians that happened to own the land on which the mines were opened. The Quapaw tribe was the most fortunate. One of them, Jackson Barrett, is credited with a subscription of \$650,000 to the first Liberty Loan, a fact that proves that he is indeed a true American. An organization known as the United States Five Civilized Tribes War Savings Society has been formed to assist the campaign for war-savings and our bronze fellow-citizens are showing a fine spirit in the matter. Turning to more technical matters, we learn that among the modifications of the local milling practice is an attempt, suggested by Mr. Persifor G. Spilsbury, to grind the tailing from the rougher jigs in Harding mills using balls, so as to reduce the pulp to 1½ millimetres, before treatment on James tables, followed by flotation. Preliminary tests show a recovery of 80% by this method, as against 50% by the current practice. Whether this new departure prove successful or not, it is pleasant to record an intelligent effort to break away from the crudities of the Joplin tradition; indeed, it is safe to say that the introduction of real Western ideas into this Near Eastern mining region should prove usefully stimulating to progress.

OUR contemporary the 'Tonopah Miner' writes with considerable feeling concerning the plague of apex suits that sap the vitality of mining enterprise in Nevada, being moved to do so by the conclusion of the White Caps v. Morning Glory case, with a backward glance at the Booth v. Jumbo Extension and Jim Butler v. West End contests. Local opinion appears to favor the victory of the White Caps, because the litigation looked like the attempt of a neighboring company owning ground covering a small part of the orebody to take advantage of a legal technicality in order to get hold of the ore that had been originally found and developed by the White Caps. Such is the view taken by our contemporary, who asserts that the lawsuit has caused a "practical suspension of all new enterprise in the Manhattan district." The pleasure given by the adverse decision against the Morning Glory is said to be an "unconscious mass of expression of antipathy" against the apex law, and the 'Miner' has pledged itself to fight for the repeal of it. With the irritation thus expressed we are bound to feel sympathy, for it cannot be doubted that the undermining of property-rights caused by apex suits, usually the consequence of the natural vagaries of ore deposition, does intimidate enterprise. Unfortu-

uately, however, no repeal of the extra-lateral law would be retroactive and therefore it could not help the owners of claims already located in Nevada or in any other State, and even the introduction of vertical side-lines would not prevent the present owners of apex rights from invading later claims in pursuit of ore; in short, the depredation of the apex-owner would persist, whereas the new claim-holder would be unable to retaliate. The apex law is a lamentable fact.

Flotation Litigation

On March 8 the Ninth U. S. Circuit Court of Appeals, in San Francisco, heard the arguments in the case of *Minerals Separation v. Butte & Superior*, and in our next issue we shall publish a description of the proceedings. It is probable that we shall also publish a part of the brief on each side, believing that arguments and briefs alike will interest the large number of our readers that are not indifferent to the litigation over the patents controlling the use of the flotation process. No modern metallurgical process has found so wide an application as flotation, therefore the decisions of the various courts, particularly that of the U. S. Supreme Court, have been awaited with an anxiety far from academic. It is of the utmost importance to the mining industry to know, as finally it will, whether it is to continue under tribute to a patent-mongering company that has shown an overbearing spirit, or is to be free to proceed with the use and improvement of a method of milling relatively so simple and cheap. We are prejudiced in the matter, as our readers are aware, and our prejudice is based on reasons that are neither personal nor commercial. We are partisans for the mining industry, which, we have become convinced, is threatened by a burdensome exaction and endangered by an unjustifiable imposition. We may say frankly that our own study of the history of the process, particularly the description by Mr. James Hebbard of the early work at Broken Hill, as published in our issue of September 4, 1915, and in the book 'Flotation,' together with hints and various items of information concerning the work done prior to 1905, has convinced us that Messrs. Ballott, Sulman, and Picard were not the 'discoverers' of the agitation-froth method of flotation. The 'discovery' was made, we believe, in the Central mill at Broken Hill between 1901 and 1903, that is, two or three years before the alleged discovery in the Minerals Separation company's laboratory in London, when a series of experiments, by varying the temperature, time, and proportion of oil, particularly the last, are stated to have led to the sudden recognition of the basic principle of flotation and prepared the way for the master patent. We believe that any one of three or four men, among them Mr. Hebbard, and others whom we have definitely in mind, could give testimony that would prove our inference that the wonderful discovery of March 1905 was merely a camouflage device to establish an invention the principles of which had been known

and demonstrated in the Central mill at least two years earlier. Those that could give testimony to this effect were formerly employed by the Minerals Separation people, or were otherwise associated with them, so that their personal loyalty conflicts with their public loyalty, to wit, the wish to serve the profession and the industry. They could be subpoenaed, of course, but an unwilling witness is proverbially dangerous, and we regret greatly that, for this reason, the truth, and the whole truth, about the origination of the agitation-froth process is withheld. Next, as we are reviewing the litigation on the eve of another critical decision, we venture to express surprise at the failure of the defence to make use of the facts of the Elmore vacuum process. Messrs. Jackling, Clanning, and their associates bought the American rights to the Elmore vacuum process in May 1915, for only \$50,000, but they have done nothing to develop it, although it antedates Minerals Separation's basic patent, No. 835,120, by a year and involves the use of a diminished proportion of oil. If they had expended as much ingenuity in developing the vacuum process as they did in circumventing 835,120 they could, ere now, have evolved a successful method of milling that might have put Minerals Separation out of court, for, as a matter of technical science, we know now that the various suppositions on which 835,120 was based are illusions. There is no 'critical' proportion and there is no need for a special kind of violent mechanical agitation. Apparently the controllers of the big copper companies feared to place themselves in the hands of the Elmores, who might have proved as exacting as their competitors, but the fact remains that the American courts have been allowed to ignore the Elmore vacuum process, in which as little as 0.15% of oil has sufficed to give commercial results, whereas the establishment of this fact ought to have gone far to invalidate the claims of Minerals Separation. Even now it seems feasible for the holders of the rights under the Elmore vacuum process to bring suit for infringement against Minerals Separation, provided that the Elmore method is developed to a successful milling operation on the ore from an American mine. Here we must lay emphasis on the fact that the British and Australian litigation between the Elmores and Minerals Separation was concerned with the older bulk-oil patents of Elmore and not with his later vacuum process, which used air rather than oil and was never made the crux of any lawsuit between these protagonists. The introduction of the bulk-oil suits into the record of the recent trials only confused the issue as between Minerals Separation and the supposed infringers in this country. Looking back, and with the wisdom that can be shown when writing last year's almanac, it would appear to us that the case against Minerals Separation has been handled badly; they have had the benefit of more than the 'rub of the green'; but we expect to see the issue contested henceforth with more psysical intuition, for when all is said and done, judges are human, they are pharaohs not sphinxes, and their methods of ratiocination have to be anticipated by learned counsel.

DISCUSSION

Alaska Juneau

The Editor:

Sir—In your article on the Alaska Juneau enterprise and its disappointments, in your issue of February 9, there are several misstatements, and, knowing that you wish to publish only facts, I take this opportunity of calling to your attention portions of the article that are untrue and misleading.

In your discussion of the allotment of interest in Mr. Bradley's Alaska Juneau contract, you stated:

"Another third to the San Francisco Exploration Company, a partnership consisting of Messrs. J. H. Mackenzie, M. L. Requa, and F. W. Bradley. The allotment of these participations, we believe, was prompted by motives of loyalty and friendship, not with the idea of spreading the risk."

The facts are that the San Francisco Exploration Company was incorporated in 1907 with 300,000 shares at \$1 each. The cash paid-in capital amounted to \$261,255 and was derived from the sale of 15,000 shares in the Nevada Consolidated Copper Company. F. W. Bradley, M. L. Requa, and J. H. Mackenzie each contributed 5000 shares. Prior to the date of the incorporation, and before Bradley, Requa, and Mackenzie had become jointly interested in mining ventures, Mr. Requa was the means of putting both Bradley and Mackenzie into the Nevada Consolidated, which proved a very profitable venture. With the profits derived from this source was laid the foundation of the San Francisco Exploration Company. Afterward, as money was needed, each of the partners contributed to this company and each participated in many ventures, some of which were profitable and some otherwise. It was the duty of each of the partners to offer anything he might discover or procure in the shape of oil or mining ventures to the San Francisco Exploration Company, and motives of loyalty and friendship had nothing to do with it. Further on you state:

"Mr. Bradley strongly opposed a public flotation." * * *. "Under pressure of the wishes of his two immediate associates, Mr. Bradley also consented to a flotation."

For several months prior to the flotation, the Alaska Juneau was borrowing money and becoming further involved in debt. At the time of financing it owed \$600,000, and everybody connected with the company was concerned, including Mr. Bradley, as to how we were going to carry on the work and pay off the loans. At a con-

ference held on January 23, 1915, William H. Crocker, Wellington Gregg Jr., F. W. Bradley, M. L. Requa, and J. H. Mackenzie being present, the financial condition was discussed. Mr. Bradley had just returned from New York, where he had refused an offer made by B. M. Baruch of a \$3,000,000 bond-issue, convertible into shares at \$8.75—the bonds not to draw interest before July 16, 1916. Mr. Crocker, the largest shareholder in the Alaska Juneau Gold Mining Co. at that time, asked on what grounds he had refused this offer. Bradley replied that Ogden Mills and he wished to retain their present percentage in the property and feared Mr. Baruch intended to get control of the shares and turn the management of the property over to the Alaska Gold Mines Co. Mr. Crocker replied that it was very dangerous for an enterprise to contract large call-loans and that it was almost an axiom that any enterprise in which this practice was pursued sooner or later would be sure to get into trouble. The property was looking exceptionally well at this period and the feed to the 50-stamp pilot-mill was averaging over \$1.50 per ton; in fact, never before nor since has the Alaska Juneau looked as well as it did for the twelve months between May 1914 and June 1915, and any opposition to public financing that Mr. Bradley may have made was because he thought, as we all did, the property would come up to our expectations and was a good permanent investment, and of the further fact that he feared he might lose control.

In discussing the design of mill and the Requa circular, you state:

"Mr. Bradley was inclined to be cautious, the technical opinion at his disposal being divided as to the kind of crushing and pulverizing machines best adapted to the Juneau ore. Unfortunately early in 1915 he became ill, and in May he had to go to Honolulu to recuperate. During his absence Mr. Requa issued a circular, dated May 4, 1915, repeating that the mine contained 80 to 100 million tons of ore 'on which a profit of from 70 cents to one dollar per ton will be realized.' He suggested the probability that 240 to 300 million tons might become available. He referred to the Treadwell mines as having a lode of undiminished value and size down to 2000 feet below sea-level and predicted the continuity of the Juneau orebody to 'an indefinite depth.' He announced that George O. Bradley, who had been consulting engineer for the Utah Copper Company, was to design and supervise the erection of a mill having a capacity of 8000 tons per day."

On April 6, 1915 (more than two months prior to Mr.

Bradley's departure for Honolulu), he signed a contract on behalf of the Alaska Juneau Gold Mining Co. with George O. Bradley, representing Bradley, Bruff & Labarthe, wherein it was mutually agreed that the latter was to "undertake the design and superintend the erection of the 8000 tons daily capacity milling-plant for the above mining company, together with the necessary auxiliary departments, such as power-plant, crushing-plant, etc." In a letter to Mr. Requa, on April 6, 1915, Mr. Bradley said:

"You will be pleased to learn that we have today closed a contract with George Bradley, and his associates, for the building of our new mill in accordance with enclosed copy of contract itself, and in accordance with enclosed copy of my letter of today to Phil."

On the same day he wrote his brother, Philip R. Bradley:

"Mr. Mackenzie and myself have made a definite business arrangement with George Bradley to take complete charge of the designing and erection of our new milling plant, to have a capacity of 8000 tons per day. This means that George Bradley, or his representatives, will have charge of all experimental work in the present mill, and of all work of every kind in connection with the new rock-crushing and milling plant. You are to give George Bradley, or his representatives, every assistance and every facility that you see they may need or that they may have occasion to ask for."

On January 28, 1915 (over three months prior to Mr. Requa's circular), Mr. Bradley, in a letter to Mr. Crocker, made the following statement:

"The mining chances below the Gold Creek tunnel promise an addition of twice as much tonnage of the same value as I believe the vein will yield above the Gold Creek tunnel. These mining chances are based upon the fact that in a parallel vein two miles away on Douglas island the orebodies (of a higher value per ton) are now being mined at a profit from a depth of 2000 ft. below sea-level. At this depth below sea-level, the Douglas island orebodies still hold their size and average values."

In the circular of May 4, 1915, Mr. Requa merely quoted Mr. Bradley's own statements regarding the engagement of George O. Bradley and the probable chances of tonnage and profits below the Gold Creek tunnel. In your comments on the foregoing you state:

"Shortly after this optimistic announcement the directors, in Mr. Bradley's absence, gave full authority to Mr. Mackenzie, as consulting engineer, with instructions to do whatever was necessary to expedite the preliminary mine work and to design and erect a mill of 8000 tons capacity. Two years later, on March 31, 1917, the new mill was ready to start. At the end of May, Mr. Mackenzie relinquished his duty as consulting engineer."

On April 6, 1915 (more than two months prior to Mr. Bradley's departure for Honolulu), he wrote the following to Mr. Requa:

"You will also be pleased to learn that I have made a definite business and mutually satisfactory arrangement

with Mr. Mackenzie to act as exclusive consulting engineer for the company beginning 1st inst."

Early in June 1915, Mr. Bradley was preparing to go to Honolulu, and on June 4 the board of directors of the Alaska Juneau company passed the following resolution:

"Resolved, that pending the return of F. W. Bradley from Honolulu, and thereafter until he shall have resumed the active personal direction of the affairs of this company, Mr. J. H. Mackenzie, its consulting engineer, is hereby authorized and instructed to do and perform all acts necessary to the development and equipment of the company's mine for the output of 8000 tons of ore a day and to further do and perform all acts necessary in connection with the design and erection of the 8000-ton daily capacity mill already provided for."

The resolution shows on its face that it was only passed pending the return of Mr. Bradley and in order to carry on the business of planning a mill and further developing the mine during his absence. The authority was not given Mr. Mackenzie during Mr. Bradley's absence, or without his consent. On the contrary, the resolution was passed because Mr. Bradley had given notice that he was going to Honolulu to benefit his health and did not wish to be troubled with business affairs during his absence.

It is to be regretted that the capacity of the ball-mills has not come up to expectations, but, when the type of mill was under discussion, all available information indicated that ball-mills were a success and especially efficient on coarse feed of minus $3\frac{1}{2}$ inches, making one easy step and eliminating stage-crushing. In Alaska Juneau practice owing to the toughness of the meta-gabbro and the large flat pieces of slate that pass the coarse crushers the capacity of the ball-mills is greatly reduced. The installing of rolls between the coarse crushers and the ball-mills, thereby reducing the ball-mill feed from minus $3\frac{1}{2}$ inches to minus $\frac{3}{4}$ inch, will undoubtedly bring the mill up to its intended capacity of 8000 tons daily and, in addition, will reduce the load on the ball and tube-mills, ensuring grinding to proper fineness, and increasing the percentage of recovery. This intermediate crushing will add to the mill cost not to exceed 5 cents per ton.

At the present time the total cost of mining, transportation, and milling at the Alaska Juneau is about 65¢ per ton, which is somewhat lower than the cost at the Alaska Gold. To say that the "mill as it stands is a failure" is not true; neither is it just to the shareholders to point to the mill as the cause of all the Alaska Juneau disappointments. The principal trouble with Alaska Juneau is that the ore milled during the year 1917 did not contain sufficient gold. For months prior to and after the financing of the company the unsorted ore crushed in the 50-stamp pilot-mill assayed about \$1.45 per ton and over 200,000 tons of this grade of ore was milled. If the Alaska Juneau plant were now running on this grade of rock the company would be making a good profit; but such is not the case. If the mistakes made in the estimates of gold contained in the ore

and in the design of the mill were honest ones, then it is ridiculous to say that either the public financing or the type of mine were forced upon Mr. Bradley.

Mr. Bradley has been manager of the Alaska Juneau property for over sixteen years, has employed all the superintendents that have operated the property during this period, and the hand-sampling and the mill-runs have all been done under his direct instructions; therefore, he has been in a position to interpret these results as well or better than his associates. The company records show that he was not absent when the consulting engineer, or the firm of Bradley, Bruff, and Labarthe, was employed, but signed the contracts himself. He, personally, signed each and every contract for mill-machinery, the power-plant, and building-material. When he returned from Honolulu, there was not a single drawing of the mill finished, or a contract let, and he had ample time and authority to change the program to stamp practice, rolls, or any other type of mill that he wished.

In May 1917, I relinquished the salary attached to the position of consulting engineer for the Alaska Juneau, but did not relinquish and had no intention of relinquishing the duties of the position, and since then have, at all times, tried to assist in solving the difficulties met with in starting the new mill. Between the 5th and 10th of each month, Mr. Bradley receives from his brother, P. R. Bradley, the manager at Juneau, a cable giving the details of the previous month's operations. This information is sent out to a few favored shareholders, but since October 1917 Mr. Bradley has not seen fit to give the board of directors this early information until it appears in the manager's monthly report, which comes to the directors from 60 to 90 days later. If Mr. Bradley has assumed all the responsibility of the management of the Alaska Juneau company, it is because he wishes to do so and not because his associates have not been willing and ready to assist him.

J. H. MACKENZIE.

San Francisco, February 28.

Sampling Diamond Deposits

The Editor:

Sir—I have read, with much interest, the discussions appearing during March, April, and May in your paper on the sampling of ore deposits of low grade. Among these a peculiarly ticklish problem is presented by diamantiferous pipes. According to the value of diamonds one admits generally that a 'pipe' is interesting if it contain 5 carats per 100 loads and that it is exploitable (for diamonds of an average value) if it contain 10 carats per 100 loads, these limitations being equivalent to 1 and 2 grammes respectively per 30 metric tons. The figures are the extreme, and if one regard the influence of the size of the diamonds and of their erratic distribution in the kimberlite one perceives how difficult and delicate a problem is presented to the engineer.

In Katanga (Belgian Congo) there have been uncovered up to date 25 pipes of kimberlite penetrating, like punched holes, the horizontal beds of the Kundelunga series, of the same age as the Karoo. These pipes were sampled in two ways: (1) On some of them one opens paddocks and treats in the rotary concentrators the whole of the tonnage extracted, varying from 200 to 1000 tons. Several small diamonds, some of 2 and 3 carats, have been collected. This sampling evidently is irrational and does not justify any conclusion except as to the core or as to the paddocks over the pipe; (2) in other places there has been adopted the system of sampling by a network of square meshes of 100 metres per side, with sampling pits (2 m. in square section) in the centre of each mesh. Unfortunately one is limited to a superficial sampling barely entering the 'blue ground,' and only 50 to 70 tons of material (yellow ground and blue) can be treated per pit. This method of sampling, distributed systematically over the entire surface of the pipe, is rational, but can one, with the small quantity of ore treated and the slight thickness of the slice removed, infer therefrom the value of the deposit?

The diamantiferous pipes belong to that class of deposits in which ordinary sampling, based on small quantities of ore, does not permit one to draw definite conclusions. I would be glad to have your advice, so competent, concerning the sampling of this type of deposit of small extent at the surface, low in grade, erratic in distribution, and unequal in value, based on the size and quality of the mineral sought.

F. F. MATHIEZ.

Rungu, Belgian Congo, October 12, 1917.

[We have taken pleasure in translating this letter, written in French. We shall apologize to Mr. Mathiez if we have failed to give his exact meaning. Despite his compliment, we do not feel competent to advise him specifically, but, knowing that Mr. Gardner Williams is in San Francisco, we shall ask him to express his opinion. —EDITOR.]

BLISTER COPPER, says Lawrence Addicks in 'Metallurgical & Chemical Engineering', as produced directly by the converter, does not make good anodes, and with few exceptions it is further refined in a special furnace, so as to reduce the work of the tank-house to a minimum. In principle the complete refining of copper involves (1) the oxidation of all elements more base than copper, removing them by slagging or volatilization, leaving only silver, gold, and the platinum group alloyed with the copper; and (2) the oxidation of the copper at the anode, leaving the noble metals in the slime. In the first stage an air-blast oxidizes some of the impurities directly, along with some of the copper. The Cu_2O formed dissolves in the bath, reacting with elements that have a greater affinity for oxygen (O_2) than does copper, thus liberating an equivalent amount of the copper. The basic oxides are slagged while the excess of Cu_2O is reduced by poling.

The Kansas-Oklahoma-Missouri, or Komspelter, Zinc Region—II

By T. A. RICKARD

THE MINES. My first visit underground was made at the Netta mine, of the Picher Lead Co. Descent in a bucket to a depth of 270 ft. brought me to a large open stope 12 to 30 ft. high. It was like dropping through a hole into an underground cavern. The shaft had been cribbed until hard rock was reached, at about 60 ft. from the surface; the stopes were not timbered; the mine, like

rock being cemented by brown zinc-blende. On other faces coarsely crystallized galena was to be seen in patches. The ground was wet, but the water was underfoot, having been drained by adjacent mines down to the working-level. On returning to the surface the bucket, or 'can,' whirled around so much as to cause one of our party to become giddy; it is possible that a tenderfoot

A CHARACTERISTIC STOPE, SHOWING MACHINE-DRILL AT WORK, ALSO 'CANS'

a real gentleman, had no visible means of support except such as nature provided. Pillars 20 ft. thick had been left at 35-ft. intervals and arranged zigzag. A bed of chert made a safe roof. That reminds me of two green-horns that were set to work in a neighboring mine where timber is used; they noticed it and wanted to quit forthwith; on being asked for a reason, one of them exclaimed, "That drift is dangerous, they've got it propped up with wood." To which one may remark that the underlying idea was not far wrong, in so far as rock is a better support than wood.

The ore of the Netta mine was in brecciated chert, the

might be endangered by loosening his hold of the rope under such conditions. The Netta mine is named after the Indian woman that owns the ground. Five acres have been stoped and 79 acres are to be under-cut in the same way. Two shafts (each 5 by 7 ft.) are in operation. The impression made by one's first visit is that the mining is delightfully simple; the ore is easy to follow; the ground stands well; and the shallowness of the deposit facilitates exploitation.

The next mine to which I went was the Underwriters No. 1, where stoping was in progress at a depth of 151 ft. Here the mineralization along lines of brecciated rock,

KITTY

BEAVER

SHERIDAN

ADAMS

or 'watercourses,' had formed a series of lodes separated by intervals, 8 to 30 ft. wide, of barren chert. Half-formed crystals of light-brown sphalerite, or 'resin-blende,' lay on the fracture-planes of the chert and also on the calcite that lined the fractures. A vug, or geode, of clean blende might be seen ten feet from a patch of coarse galena, filling a cavity.

The third mine that I visited was the Woodchuck. Here the shaft was 150 ft. deep, cribbed nearly all the way, down to 125 ft. from the surface. The first observation to be made on arrival underground was the black streaks of 'tar' dripping over the faces of the stopes. Such a sight is not uncommon in the district. The so-called tar is an asphaltic oil, containing only 8% solid asphalt. The Woodchuck mine is 200 ft. from Tar creek, a small sluggish stream the name of which originates from the seum of oil readily observed on the surface of the water. The tar seeps through the roof of chert, suggesting permeability. Not long ago a pocket of tar was cut in the stopes and smeared the broken ore in such a way as to make a miserable mess in the mill. The question arises: if the ore naturally contains tar, and if it be mixed with other ores in the district free from tar, might not enough tar be present in the mill-feed to facilitate flotation? If this natural tar were present in a proportion suitable for a frothing-agent, would Minerals Separation or any other patent-owning corporation be entitled to collect royalty on the use of this metallurgical ingredient? Also, does not the tar in the mill-feed cause a loss of valuable mineral, by floating the slime when concentrating in the jigs and on the tables?

The superintendent of the Woodchuck, C. W. Ritter, took me down the No. 1 shaft. The faces of ore showed the 'jack,' or blende, 'frozen' to the flint; it is not easily sorted, whereas the galena occurs in pockets or patches, so that it can be broken clean. I saw nine-inch cubes of galena, and Mr. Ritter told me that he had obtained many crystals 12 inches cube. He shipped one carload (50 tons) assaying 84%. Occasionally chambers, or big vugs, are penetrated in the course of stoping; these may be lined with crystals of galena, providing a sight of rare beauty. Returning to the surface, we descended through the No. 2 shaft, which is 212 ft. deep, to another

stopping area at 265 ft. Here the ore-bearing chert was darker and the mineral was chiefly resin-blende along the bedding-planes where these had been crossed by nearly vertical fractures. The ore-bearing rock was capped by gray chert. The light from the lamps was reflected from the facets of galena and blende, also from the dripping tar, affording a brilliant display.

MINING AND MILLING PRACTICES. This has been essentially a 'leasing' region. Lessees are proverbially shortsighted, for a sufficient reason; they gut a mine. As soon as the ore runs below grade and the royalty threatens to kill the profit, they quit, and go elsewhere in search of a better opportunity. Joplin has been a synonym for the precarious in mining. When other districts failed to give remunerative employment the miner of the Middle West could always go to Joplin and get a lease on a 5-acre patch. All that he needed in the way of equipment was a one-lunger 8 by 8 engine taking steam from a 10-hp. boiler, with a 1000-lb. can at the end of a $\frac{3}{8}$ rope. The boiler was mounted on top of a derrick, so that the hoist-man could attend to the boiler as well as perform more customary duties. The shaft was a 5 by 7 hole lined with "kindling wood and matches," an old-timer phrased it, meaning anything on which he could lay his hands. It was a rough and ready equipment and a short-lived operation, but it had the merit of being economical and of being adapted to the immediate purpose, which was the extraction of small bodies of low-grade ore at a shallow depth. As for his mill, when the lessee had to build one, he did not draw a plan, "he just went out and built it." The Joplin mill became a synonym for cheap and successful crudity. Classification was ignored. Rough jiggling, sometimes done by hand, sufficed. If it did not, then the rough concentrate was re-jigged; that was all. As for marketing the product, that was equally simple. The lessee placed it in a bin until such time as the buyer, the representative of some smelter, came along and sampled it by mere inspection of a handful, as an expert buys tobacco. Only within recent years has buying been based on an assay. In a day or two he got a bid from this buyer and from others that had tested his product in a similar way. The mining was simple, for it in-

MC CONNELL

LUCKY JUNCTION

SKELTON

WOODCHUCK

CROESUS

involved no timbering, thanks to the fact that the ore, about 8 ft. thick, was covered by a bed of flint that became the roof of the stope, which was only 100 to 200 ft. below the surface. The milling was simple because the zinc-lead ore consisted of coarsely crystalline blende and galena, in the proportion of 5%, in a hard chert that was easily detached from the valuable mineral; and, best of all, the Joplin miner was his own master, he worked with one or two partners, he was independent of unions and

been affected by the uncertainty of the mining, for operations in the older districts of Joplin and Webb City were dependent upon relatively small reserves of ore and upon a market of the most uncertain kind. A visitor might

A PILLAR TO SUPPORT THE ROOF

A SHAFT, SHOWING UNTIMBERED OPENING

of corporations; he was an American, not a Dago or a Bohunk; he could look any man in the face and tell him to go to hell!

The mills give a first impression of sloppiness and inefficiency. The character of the ore-dressing practice has

come to Joplin and find seven or eight hundred small mills at work in the surrounding country and if he returned six weeks later he might find half a dozen of them idle or moved elsewhere. A look of impermanence characterizes the older mill-buildings; they suggest that

their owners take short views of life economically. The interiors are dark and dirty. Boys seem to hang around in a desultory way. At Carterville I watched a man with shovel and wheelbarrow removing concentrate ten yards; soon a two-horse wagon came with two men, who shoveled the concentrate into the wagon. It looked unmethodical and unintelligent, but it was explained to me that the buyer's men did the second shoveling into the wagon and that this was an old custom, the idea being that during the transfer of the material it underwent mixing, so that a better sample could be obtained when it was shoveled, for the third time, into a railroad-car and spread upon the floor so that a number of auger-samples could be taken. It would seem as if the buyer and seller could unite in devising some more economical method. Systematic weighing, sampling, and assaying are conspicuously absent in the milling practice, because the cost of such checks, I was told, would equal the whole cost of milling. *Credat Judaeus Apella.* The assay of the tailing, as a check on the milling, is inadequate because it may record the presence of non-recoverable mineral—the fine flaky blende—nor does it include the slimed sulphide that floats away. Flotation might be used as a check on mill-losses, if for no other purpose. Without being supercilious, it would seem as if an effort to keep the machinery in better order, by maintaining everything ship-shape, and pitching the mill-work on a higher key of attention, might reduce the cost of milling, at least in such mills as I happened to see at Carterville. In a mill in the Wisconsin zinc district where 6 men used to be employed to treat 5 tons of ore, now 3 men suffice to attend to the milling of 50 tons. One can never tell until one has tried.

Undoubtedly the leasing system is not stimulating to innovations. The short life of the enterprise is a deterrent to experimentation. On the other hand, it intensifies the mining operations. The owner of the ground, originally a poor farmer, may not have the money to mine himself nor perhaps the experience warranting him in risking a mining venture. Therefore companies are organized to lease, to open up the ground, to prove its possibilities, and then to sub-lease it in small tracts. One bad result is the cumulative increase of the royalty, which may rise to 25%. Formerly it was 10% straight; now it is based on a sliding scale regulated by the prices of zinc and lead. This helps the lessee to weather the bad times. On the whole, one may question whether the leasing system is well adapted to low-grade mining; it is far better suited to rich ore, such as that of a precious-metal mine.

In criticizing the local milling practice, one must remember that the matrix of the valuable mineral is extremely hard—flint—and that comparatively coarse crushing (35-mesh) suffices to separate the proportion (60%) of mineral that is recovered in the concentrate. Only 5 to 15% of the mill-pulp, in its usual state, is suitable for flotation, owing to the coarseness of the grinding and the non-sliming character of the ore. At the Woodchuck mill, for example, C. C. Burger (Penn-

sylvania '90) informed me that the total cost was \$1.75 per ton of ore and \$25 per ton of concentrate; the ratio of concentration being $12\frac{1}{2}:1$, the recovery 8% in a concentrate containing 60% of combined zinc and lead as sulphides. The tailing contains 1.5% combined zinc and lead; allowing for loss in slime, the total loss would be at least 2% of combined zinc and lead. The recovery is estimated at 70%, but this is considerably better than the average of the district. The flow-sheet of the Woodchuck mill is typical of the best local practice. From the Blake crusher the ore goes to Cornish rolls and then to trommels, yielding a $\frac{3}{8}$ -in. product. The undersize from the trommels goes direct to Cooley 'rougher' jigs having five compartments, each measuring 36 by 48 inches, with screens having openings varying from $\frac{1}{8}$ to $\frac{1}{12}$ inch. The middling, or 'smitten' (another local term), from these jigs goes to a 7-compartment 'cleaner' jig and is not re-ground. The tailing, or 'chats', recovered from the last three beds of the rougher jigs is re-ground and passed through a trommel having $\frac{1}{2}$ -in. openings to be treated on a separate jig together with the sand from the last two hutches of each rougher jig. The overflow from the end of these 'sand' jigs, with the exception of the cleaner tailing, which is treated on the sand jig, passes over dewatering screens having $1\frac{1}{2}$ to 2-mm. apertures. These undersized products are then diverted to settling-tanks, the overflow from which passes to a Dorr thickener of 50 ft. diam. on their way to a set of 16 tables. The product from the settling-tank is screened to $1\frac{1}{2}$ mm. by a trommel, the oversize being re-ground so as to pass through this trommel, while the undersize is divided and then treated by hydraulic classifiers, producing six different classes, the coarser product going to six Arbutnot tables having the Overstrom motion, while the finer material goes to six Wilfley tables. The product of the Dorr thickener is treated by four Deister-Overstrom slime-tables.

The recovery of zinc in the form of concentrate ranges from 55 to 65%. C. A. Wright says that the recovery of 68.6% at a mill discussed by him, is "somewhat higher than the average zinc-recovery throughout the district." At the mill described by him only 2.31% passed a 65-mesh screen. This represented 44.44 tons of pulp containing 5.24% zinc, or 2.328 tons of metal. The overflow from the settling-tanks contained 34.73 tons of solid, assaying 5.01%, making 1.74 tons of zinc. Thus 79.17 tons of pulp, assaying 5.14%, and containing 4.068 tons of zinc, would be available for flotation. He concludes that an additional saving of 10.6%, bringing the total recovery to 79.2%, might be made. The main difficulty, of course, is the fine grinding. The flinty matrix renders such work unusually costly. Experiments have yet to be made in order to ascertain the kind of machine best adapted to the work. The demand made by the process-mongering company, Minerals Separation, namely, 2% on the value of all the products of a mill, however produced, is a decided deterrent to the general use of flota-

'Flotation of Lead and Zinc in the Joplin District,' M. & S. P., Oct. 20, 1917.

tion. Six flotation units were at work at the time of my visit, last October, in plants having a capacity ranging between 25 and 100 tons per day. For the present the best prospect seems to be offered by the re-treatment of the dumps in the older localities, such as Joplin and Webb City. This material can be jigged and then re-crushed to 60-80 mesh, the product going to the flotation-cell. A test made by J. M. Callow, at Salt Lake City, showed 456 units of zinc in the original sample; when this was jigged it yielded a concentrate containing 380 units. After grinding to 60-mesh a recovery of 320

FIG. 1. SECTION OF A STOPE

units was obtained by flotation. Thus 69% of the zinc was recovered in the form of a 60% concentrate.

A typical enterprise in Oklahoma may be described. A unit of area is 40 acres. To test this tract it would be necessary to do 10,000 ft. of drilling at \$1.50 per foot, making \$15,000. In order to mine systematically, two shafts, each 260 ft. deep, would be sunk at \$6000 apiece. With incidentals the shafts would involve an outlay of \$15,000. Thus the preliminary work would entail about \$30,000, excluding the cost of pumping, which is too variable to allow of averaging. Occasionally a flow of 3000 gal. of water per minute has to be overcome; this may require six months of pumping to lower the water-level so as to permit of comfortable mining; the maximum cost may run to \$45,000. However, this item is of decreasing importance and is now rarely burdensome because the water-level in the district has been depressed to the ore-horizon, or just below it, along several of the 'ranges' or groups of 'runs,' in other words, the main lode-channels.

Here I may refer to an incident of mine-drainage. In 1911 T. F. Lennan (Tech. '99) was superintending the sinking of a number of shafts on the Miami Zinc & Lead Co.'s ground. At 260 ft. he placed a pumping equipment that drained the whole Commerce sub-district. The level of ground-water was at 200 ft. He sank the main shaft in shale and extended a drift to within ten feet of the ore in dry ground under the shale-chert contact. There he built a cement dam preparatory to penetrating the water-zone along the contact. He made an iron door with suitable valves in the dam. Upon penetrating the wet ground the water flowed at the rate of 2000 gal. per minute, draining the neighboring ground immediately. Mr. Lennan asked his neighbors to contribute to

the cost of the pumping. They were unwilling. Thereupon he closed the valves in his iron door and stopped the drainage. Soon they 'came across' and paid \$100 per month toward the expense of pumping—12 of them. This pumping plant drained three miles each way along the Miami fault.

The mine having been started, there comes the need of a mill. One of 600 tons capacity per 24 hours will cost about \$80,000. This will cover the expense for a complete plant, including power equipment, but not flotation and its attendant royalty. Stores to the value of \$15,000 will be needed when starting the mine and mill. The drilling and shaft-sinking, as we have seen, will cost \$30,000; the hoist, boilers, head-frame, compressor, drills, track, and accessories will cost \$50,000. The total outlay is \$175,000; it may be taken as ranging between \$150,000 and \$200,000.

The time required to establish a going enterprise may be inferred from the record of the White lease of 80 acres. Drilling was started on October 10, 1916. By March 1, 1917, a reserve of 600,000 tons had been proved. A start to build the mill was made on February 28 and the mill was running on May 2. The mill has a capacity of 750 tons per 24 hours, it being necessary to be specific because many of the mills do not run full time. This record, made under the management of Persifer G. Spilsbury (Lehigh, '05), is probably above the average for speediness, but it will serve as an example. The enterprise was started and put in full swing within seven months.

To return to our 40-acre lease. The ground should yield 40,000 tons of concentrate averaging 60% zinc and

FIG. 2. PLAN OF STOPES

lead. The value of this product in the future involves some guessing. In the summer of 1915 a maximum price of \$135 was paid for 60% zinc concentrate and in the summer of 1916 a maximum price of \$130 per ton was paid for 80% lead concentrate. In October 1917, when I made my investigation, \$85 was paid for the lead and \$75 for the zinc concentrate. A large tonnage of 60% zinc concentrate carrying 6% lead was being sold for \$62 per ton. The concentrate is placed on the market and sold to the smelter. What should it be worth in the future? When I asked three of the best-informed tech-

nical men in the district, one said impatiently "Not a damn!", but he revised his opinion and said \$60 per ton; the second said that \$75 was a fair expectation; the third thought that the minimum would be \$40. Upon further discussion it was agreed by those present that \$55 was a good basis for an estimate of future production.

During normal times—before the War—on a 7% reconcentrate was \$20 when the royalty was 10%. The market price of concentrate was \$45 and the cost of min-
